According to the Boston City Record, ten years will be required for putting into effect the complete schedule, which calls for the establishment of training facilities for health, fire, charities and financial officials, civil service employees, water bureau superintendents, purchasing agents, city and village clerks, park officials and assessors.

The conference has plans already under way for the training schools for fire department and charties department employees similar to those now being organized for police training, and the training of health officers is being taken care of by the State Health Department.

Venturi Meter Regulates Flow of Coagulant

A Venturi meter performing a dual role is an interesting feature of the new Huia filter station at Auckland, New Zealand. Water is carried to the filter station by a concrete aqueduct designed for a capacity of 32 m.g.d. The conduit terminates in a Venturi tube having an upstream diameter of 4 ft. 6 in. and a throat diameter of 17 in. In addition to metering the flow, the Venturi serves as a part of the coagulant dosing apparatus.

The upstream end and the throat of the Venturi meter are connected by piping to vertical concrete tubes, in which are placed copper floats. The difference in elevation of the floats is, of course, proportional to the flow through the meter, and this difference is made to control the rate at which the coagulant is admitted. The relative movement of the floats is translated into a vertical movement of a hollow arm. This arm is hinged at its lower end, is fitted with an adjustable orifice at its upper end and is connected to the tank containing the coagulant solution. The solution in the tank is kept at a constant level by means of floats. When there is no flow through the Venturi, the orifice is at the level of the solution and there is no flow of coagulant. As the flow of water increases, the orifice drops an amount proportional to the difference in head between the throat and the upstream face of the Venturi and the dose of coagulant is thus kept constant at all times.

Atlantic City's $15,000,000 Municipal Auditorium Inaugurated.—The recently completed $15,000,000 municipal auditorium of Atlantic City, N. J., was inaugurated with the convention of the National Electric Light Association, in which was staged the largest exhibition of electrical equipment ever assembled under one roof. This convention marks the beginning of the Edison Jubilee, which continues until October.

New York City to Have More Parks.—The Board of Estimate of New York City has authorized the purchase at private sale of prospective park sites in Queens and Richmond with a combined plottage of more than 632 acres at a cost not exceeding $2,250,000, from the $3,000,000 fund recently made available for that purpose.

No General Taxation for This City.—Ponca City, Okla., a municipality of 20,000 population, is stated to have the distinction of enjoying absolute freedom from general taxation. The city owns and operates its water and lighting utilities and the profits therefrom pay the entire running expenses of its municipal government.

Providing Sewer Facilities in Rural Communities

Formation of County Sanitation Districts in Kansas

By E. F. KINDSVATER
Engineer Douglas County Sewer District No. 1, Lawrence, Kan.

CHAPTER 165 of the Session Laws of Kansas for 1927, authorizes "the construction and maintenance of storm and sanitary sewers in counties having a population over twenty-one thousand and less than seventy thousand, provides for the condemnation of necessary land therefore, and provides for the payment of the cost of such sewers." This law represents the first attempt to provide sewer facilities in unincorporated suburban and rural communities.

The Why of Sanitation Districts.—The enactment of this law and the use that will undoubtedly be made of it comes as a result of the tendency in recent years of urban residents to move out into the open spaces surrounding the cities proper when building their homes. It is not only possible for unincorporated areas surrounding the larger cities to take advantage of the law, but also makes it possible for suburban villages to utilize this method in financing sewer improvements which their taxing limitations would otherwise prevent. It further provides a means for forming a district made up of urban and suburban areas, or of several suburban areas for which a system of sewers and sewage disposal could be designed which would treat the entire area as a whole, each local system becoming an integral part. The law may also prove to be of especial service to summer resort communities and tourist camps from which typhoid frequently emanates as the result of bad sanitary conditions. These resorts can now be cleaned up and given modern conveniences by the help of this law.

Douglas County Sewer District No. 1.—A residential area, located immediately west of the University of Kansas campus and not incorporated with the city of Lawrence, found it necessary to provide sanitary sewer facilities to take the place of an old and very much overloaded septic tank system. Douglas County Sewer District No. 1 was, therefore, formed in April, 1928, when the owners representing "fifty-one per cent or more of the acreage in the district" petitioned the board of county commissioners for its formation.

The board of county commissioners, after duly advertising the petition and making it possible for those not signing the petition to file their protests, employed the writer as engineer to prepare plans and specifications, and superintend the construction of a sewer system. Surveys were made, plans and specifications prepared and with application for the creation of Douglas County Sewer District No. 1, submitted to the State Board of Health for approval.

The policy adopted by the board of county commissioners was to make plans and specifications to cover the entire district and to construct only that part which was necessary to relieve the congested septic tank and provide for the immediate real estate development within the district. In compliance with this policy the commissioners advertised for bids and let the contract for about one-fifth of the complete system. Since then owners within the district have asked that the contract be extended until now the entire system is either under construction or under contract.

Rather than provide a sewage disposal plant for this area, it was found advisable to enter into contract with the city of Lawrence, making it possible to connect the trunk line for the district to one of the trunk lines of the Lawrence sewer system.

Contract Between City and District.—The contract between the city of Lawrence and the district provides: for the payment of $50 for each residence connected to the sewer system; for the payment of a portion of the expense necessary to build or rebuild main sewers in the city of Lawrence, which main sewers under present law, are paid for by the city at large; and for the payment to the city of Lawrence annually a sum equal to the amount which would be raised on all real estate in Douglas County Sewer District No. 1 by a tax equal to the levy made in such year by the city of Lawrence on real estate within the city for maintenance of the sewers of the city.

The contract further provided: that nothing shall be allowed to enter the sewer except such matters as are proper under present ordinances of the city of Lawrence, and any amendments which may be made thereto; that plumbing of any residence within the district shall be installed in conformity with the ordinances of the city of Lawrence relating to plumbing; that all plumbing shall be subject to inspection by the authorities of the city of Lawrence; and that the city of Lawrence may disconnect any residence which may be connected in any way in violation of the contract.

Provisions of Enabling Act.—Provision has been made for the creation of sanitary districts not only by petition from the people within the district, but the board of county commissioners, by resolution, may declare it necessary to build, rebuild or construct, or reconstruct any storm or sanitary sewer, disposal plant, pumping station, or other appurtenances necessary for the proper handling of storm or sanitary sewage, and for which a special tax may be levied. The resolution shall be duly published and if the owners of more than one-half of the property liable for taxation for making such improvements do not within twenty days from the last publication, file protest, the board of county commissioners shall have power to cause such improvements to be made.

The board of county commissioners may create a sanitary district within, or extend any district into, the limits of an incorporated city only upon obtaining the consent of the governing body of such city.

The law further provides, that with the consent of the board of county commissioners, private sewers may be built at the expense of the property owners interested in such improvement, and the board of county commissioners shall have the power to purchase and thereafter maintain sewers so privately built.

Costs Assessed Against Lots.—All costs and expenses involved in creating the district and subsequent construction are assessed against lots and pieces of ground contained within the district in which it is situated (exclusive of improvements), and are levied and placed on the tax roll for collection and collected in the same manner as other taxes. The county commissioners, in its discretion, may provide for payment of the costs thereof by installments, or they may provide for the payment of the entire tax or special assessment at one time.

The board of county commissioners have power to levy a special maintenance tax of not to exceed one dollar on each one hundred dollars of the assessed valuation of the land (exclusive of improvements) within the sewer district or joint sewer districts. The purpose of such fund is solely for creating a maintenance fund to be used for maintaining storm or sanitary sewers, disposal plants, pumping stations, pumps, or other apparatus used in con-

nection with any sewer district or joint sewer district.

The Douglas County Sewer District No. 1 represents the first and only attempt, thus far, to make use of this law in the state; it is, however, not the first attempt in the United States to meet similar problems.

Examples of Sanitation Districts.—The work of the Los Angeles County (California) Sanitation Districts furnishes a notable example of what may be done in solving sewerage and sewage disposal problems by the creation of sanitary districts. In 1926 there were nine County Sanitary Districts in Los Angeles County, covering approximately 432 square miles and including 35 incorporated cities, 35 unincorporated communities, and a comparatively large rural area. The nine county sanitary districts are combined to form the Metropolitan Sewerage System of Los Angeles County, which system has made it possible to treat the entire area involved as a unit in solving the sewerage and sewage disposal problems and treating each district as an integral part. The formation of sanitary districts has been especially desirable in Los Angeles County, not only to cope with the continued and rapid growth in population, but also as a means of conserving the water supply for the entire area.

Another notable example may be cited in the formation of the Sanitary District of Chicago (Illinois). The district includes some sixty municipalities, covering not only Chicago and the Edison Company Territory, but the Public Service Company of Northern Illinois, in part. Some enthusiasts feel that within twenty or thirty years the Sanitary District of Chicago will include all of Cook County. The problem there is primarily one of taking the sewage from the water supply of Chicago and surrounding area, diluting the sewage, then supplementing the dilution by treatment before turning it into the Illinois River.

State laws throughout the United States, with few exceptions, make it possible to form sanitary districts for the collection, treatment and disposal of sewage. It is evident that the development of metropolitan sewer systems must be apart from political boundaries and there must be the fullest cooperation between large cities, small cities, and the developing rural communities. The organization of metropolitan sewer districts is based on the logical grouping of such areas according to their topographic features and common interests. The practice of many municipal authorities at present in solving the immediate demands without thought of the future, will eventually lead to a very ill-advised and uneconomic sanitary scheme, to say nothing of the possible menaces to public health.

Determining Proper Boundaries of District.—A difficult problem presents itself in the determination of the proper boundaries of the sewer district. Provision must be made in correctly designing the sewer facilities for the probable future development of the community. The natural growth of the community will cover land which now may be used only for agricultural purposes, although valued at speculative prices. Such territory, if not included in the sewer district, will obviously be in line for development later and can be sewered only at great expense. On the other hand, to assess an entire township for the construction of sewer facilities which benefit only a very small portion, is clearly unjust. The engineer in establishing the benefit district boundaries must be firm in including such land which is adjacent to and in line for subdivision development and is, therefore, quite obviously benefited by the improvement regardless of the protests from those who may be thinking only in terms of the added return in sale of crops.

From the standpoint of the municipality it is contended by some that the installation of sewers in county sewer districts adjacent to a municipal corporation operates to the disadvantage of the municipality due to the fact that the district provided with sewer facilities and other utilities is not particularly desirous of being annexed to the municipality. This may be true to some extent but, generally speaking, the advantages to a community to be derived by annexation over-balance any possible disadvantages. When a district does comes into the city it represents an asset to it in the way of complete and well designed and constructed sewer systems. Certainly a municipality is fortunate in having the extensions of its sewerage system into the adjacent territory made under capable engineering supervision.

The law providing for the creation of sanitary districts contains the basic elements of a most needed and useful instrument. The refining effects of protests, court actions, experience of use, and legislative amendments, are needed now to make it applicable to all cases that may arise. The legislative amendments that seem apparent at this time would be: first, make provision whereby it would be possible to construct water supply systems in addition to storm and sanitary sewers; and second, since only 22 counties come within the limits set forth in the law, 3 counties exceeding 70,000 and 80 counties falling below 21,000 population (based on 1927 statistics), it would seem that a readjustment should be made in the population limits, possibly the limits eliminated. The act meets a real public need in connection with solving the sanitary problems for unincorporated suburban areas surrounding the larger centers of population, insuring the same regulation by the State Board of Health as applies to incorporated areas.

Acknowledgment.—The foregoing is a paper presented at the meeting of the Kansas Water Works Association.

City Responsible for Damage from Discharging Raw Sewage Into Open Stream

Cities which discharge raw sewage into an open stream and thereby damage farm lands below affected by the polluted waters are responsible to owners of the lands, according to a recent decision of the Indiana Appellate (Supreme) Court, rendered on an appeal of the city of Frankfort against an award in the lower courts to Jay D. Slipher, who brought the original suit for damages. Judgment against the city, in the amount of $3,962.07, was affirmed. Ohio Health News of Feb. 1 comments on the decision as follows:

The decision was a complete affirmation of plaintiff's contention that the city could have remedied the situation, and prevented the damage to his property, by installation of adequate modern sewage treatment works, and that the city, under the law, was responsible for damages caused by its failure in this regard. Sections of the decision of particular interest are as follows:

The contention that appellee could have obtained relief under Sec. 8125 et seq. cannot prevail. These sections simply provide a method by which the common council, the board of health of any city or town, the board of commissioners of any county, the trustee of any township, or 10 per cent of the electors of any city, town or village may file a complaint with the state board of health charging the pollution of the source of any public water supply, or that the water of any stream, spring, lake or pond is being polluted, thereby materially injuring, for domestic use, the character of the water into which the same is discharged to the injury of the public health or comfort. As shown by the title of the act of which the above sections are a part, the statute gives the state board authority to enforce the provisions of the act for the protection of the public health. The statute is not available to an individual landowner like the appellee, who suffers a special injury different from that suffered by the public. The individual landowner must seek relief through the courts, as did the appellee in the instant case.

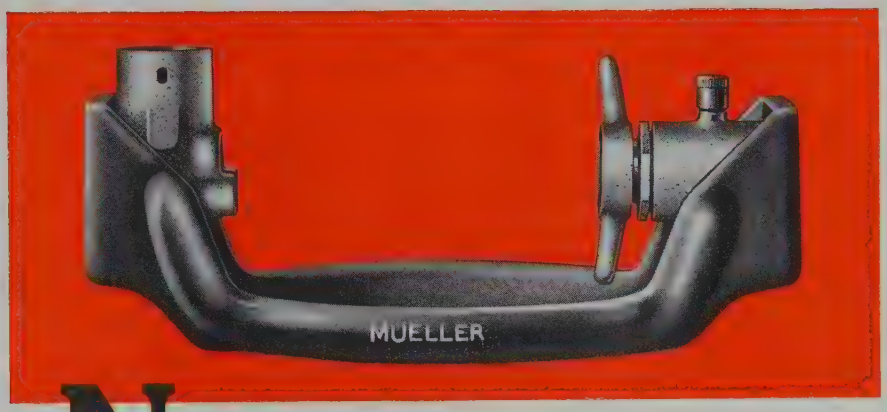
The first and second contentions of appellant will be considered together.

Appellant argues that since it is by statute authorized to build and maintain an adequate system of sewers for the disposal of its sewage, it may lawfully discharge its sewage without purification into a stream which is the natural outlet, and that so long as such discharge is without negligence it is not liable to a person through whose land the stream flows, though the water of such stream is polluted and the rental value of such land is diminished thereby.

The court, after referring to a number of Supreme and Appellate court decisions bearing upon the issue, said:

The rule of necessity thus declared must in and of itself inevitably force just the opposite doctrine, in the interest of the public health, the very thing supposed to be subserved by the rule, when it is daily becoming more and more apparent that the sewage in the streams is a real menace to the public health, and it is not a necessity, because it can be otherwise provided for, with practicability and assured safety to the public health.

* * * Under the facts as found by the court, public necessity did not call for or require the pollution of the water of either Prairie Creek or South Fork, and since appellant, by the expenditure of a reasonable sum of money, could have adopted a method of purifying the sewage, the judgment should be affirmed.



New!

Mueller Improved Meter Yoke

The new Mueller Yoke Plate No. G-10630 was designed after a complete study of all types of meter yokes on the market. It is a one-piece yoke with no bolts to rust, which drops vertically on the risers. Every feature conducive to ease of installation, flexibility, adaptability, and long life and satisfaction is embodied in this yoke.

It is very simple to install and after installation there is nothing to slip or get out of alignment.

The stop in the yoke has been given special thought because we realize it is the only means of controlling the water between the Main and the House. The outlet connection or ell, which in itself is a stop, was so designed that the sleeve can be screwed back to its limit, which forms a stop preventing a drain from the house.

This yoke may be used with any meter now on the market. Send for special information.

PLUMBING BRONZE AND VITREOUS WARE

When Winter Comes

31 States Will Need Snow Removal Equipment

Of necessity, two-thirds of all the states in the U. S. must be well equipped to service their highways during the winter months. Modern road traffic has demanded the removal of snow bound roads, and there is a substantial sum set aside in these 31 states for the purchase of snow removal equipment.

You can reach practically every one of the officials who specify and buy this equipment in the thorough coverage offered by ROADS AND STREETS and MUNICIPAL NEWS AND WATER WORKS. The former covers the huge highway market with a total 27,000 circulation, and the latter takes in the municipal field (covering cities) with a total 16,000 circulation. Here, then, is a total gross coverage of 43,000 in two leading journals which assure you the attention of your message on snow removal to these 31 states.

The September, October and November issues of these two publications will specialize and stress this work as was done in last year's ROADS AND STREETS. The specifiers and buyers have again been notified of this special snow removal section to appear in these two journals and they will be vitally interested in your message.

Our editorial columns will feature this section with much valuable information accompanied with many illustrations. The advertising pages will be greatly increased in these issues with their messages to these officials.

Our advertising department is at your service for any copy and layout assistance. Make your reservations early and blazen your advertising story through these publications which will penetrate to the officials who specify and buy snow removal equipment.

Send in your reservation now for the September, October and November Issues of Roads and Streets and Municipal News and Water Works

Operating Experiences With Large Capacity Filter Plant

Data on Purification Works of Essex Borders Utilities Commission

By J. CLARK KEITH
Chief Engineer, Essex Border Utilities Commission, Windsor, Ont.

THE operation of any filtration plant, large or small, usually gives rise to problems which are peculiar to that plant alone. Plant operation may be largely a matter of routine procedure, but there must be constant vigilance to detect the unusual condition when it does appear.

The purification plant operated by the Essex Border Utilities Commission has a nominal capacity of 21 million Imperial gallons per day. In one respect at least it is unusual, in that it is jointly owned by nine communities serving approximately 120,000 people. The capital costs were originally apportioned on the estimated consumption of each municipality five years hence. The operating costs are based on the actual amount of water delivered to each municipality. This is determined by meter measurement. The plant delivers water by gravity to two pumping stations, one privately owned by the Walkerville Water Co., which serves four communities, the other the municipal plant of Windsor, which serves the other five.

The Supply.—The source of supply is in the Detroit River and is a typical Great Lakes water. The initial source of possible trouble in any plant is naturally at the intake. Due to the constant movement of ferries between the Canadian and American shores, there is seldom an ice cover over the intake which is located in 40 feet of water about 1½ miles upstream from the ferry crossing. Under favorable conditions frazil ice develops which has adhered to the 8 ft. bell mouth of the intake, causing partial or complete interruption of flow.

In designing the low lift pumping station, the possibility of such trouble was recognized, as it has occurred in other intakes along the Detroit River. The piping from the pumps was so arranged that pressure could be applied to the intake in the belief that the ice which had formed at the mouth could be blown off. Frazil ice has appeared in this intake on three separate occasions in such quantities as to cause almost complete interruption of service. In each instance, immediate relief has been secured by reversing the flow in the intake. Large masses of ice conforming to the contour of the pipe would then come into the suction well. The average time required for the operation is 25 minutes, during which period the reservoir is being drawn upon.

Frazil ice did not appear during the past winter, though conditions, based on previous experience, were favorable for its formation. Continued cold, not common to this district, caused Lake St. Clair and the upper part of the Detroit River to freeze over and to remain covered with ice. This ice cover prevented the formation of frazil ice in that section of the river from which this supply is drawn.

The water entering the suction wells is comparatively free from the larger debris such as tree limbs, submerged logs, leaves and weeds and no great amount of these is removed by the revolving screens. Late in the autumn fairly heavy quantities of weeds find their way into the suction well. These are believed to be set free by the impellers of passing freighters. It is found that a half revolution per 8 hour shift is sufficient to keep them clean.

Application on Coagulants. — The coagulants, fed from dry feed machines, are applied to the water at the entry to the suction wells and are mixed by the turbulent action of the water in the wells, the passage through the low lift pumps and in the "over and under" type mixing chambers at the entrances to the coagulation basins. Sulphate of alumina is the principal coagulant and the dosage is determined by the quantity and quality of the turbidity in the raw waters. The dosages applied generally range from a minimum of 0.6 G. P. G. to a maximum of 3.5 G. P. D., with an average dosage of 0.89 G. P. G.

During the month of April, 1929, turbidities as high as 800 P. P. M. were recorded. The average for the month was 175 P. P. M., which is the highest monthly average noted since the opening of the plant three years ago. To reduce these turbidities to a maximum of 40 P. P. M. in the applied water and to maintain an effluent of less than 1.0 P. P. M. alum dosages from 20 per cent to 80 per cent in excess of the scheduled dosages were applied. During one 24 hour period it was necessary to apply 5 G. P. G. to a raw turbidity of 275 P. P. M. to produce a satisfactory effluent.

These unusual turbidities are believed to arise from the high water now prevailing in Lake St. Clair. Silt and sand have been accumulating on the shores for years and these have been brought into suspension by the change in lake levels. Lake St. Clair is, relatively speaking, so shallow that even a moderate wind disturbs the entire lake body.

Dosage with Iron and Lime.—Ferrous sulphate and hydrated lime were introduced as coagulants in May, 1928, in an effort to increase the length of filter runs during the "algae" period. During the month of June, 1927, it became necessary to backwash filters every 1½ hours as a result of the high plankton content of the raw water. This affected the quality of the effluent and the delivering capacity of the plant to such an extent that a remedy was sought to better plant operation during that period.

Dosages ranging from 2.4 to 2.0 G. P. G. iron and 1.8 to 1.0 G. P. G. lime were fed and satisfactory results were obtained in all cases. The maximum dosage represented a cost 2.75 times that of the scheduled alum dosage while the minimum dosage cost 1.6 times as much. The lime and iron were fed separately from two dry feed machines ordinarily used for lime. We learned by experience that they could not be fed from the same machine as in combination they formed sulphate of iron within the hopper. It was necessary to add small paddle wheels to the machine delivering lime to prevent arching over. Sulphate of alumina cost $26.20, hydrated lime $14.00 and sulphate of iron $21.00 per ton, all delivered at the plant.

Conclusions Regarding Use of Lime and Iron.—During the period when lime and iron were employed as coagulants, the following conclusions were reached or results attained:

(a) The service hours of the filters were extended to a minimum of 10 hours.

(b) The effluent did not suffer, physically, at all times having less than 0.5 parts of turbidity.

(c) The filter mat showed less signs of shrinkage and cracking than was observed during the "algae" period of 1927.

(d) Lime and iron required approximately 15 per cent more wash water per M.G. filtered than was required with alum as the coagulant when length of run and turbidities were equal.

(e) An increase in the turbidity of the raw water above 25 P.P.M. could

be met with a decrease in the quantities of coagulants used.

(f) The results obtained justified the added cost and the use of lime and iron in the "algae" period will be continued.

The period of retention in the coagulation basins ranges from 1½ to 4 hours, depending upon the demand. The basins are cleaned twice yearly, following the spring algae period and again in the late autumn. Normal procedure permits the draining, cleaning and refilling of a single basin in ten hours.

Mudball.—Mudballs appeared shortly after the opening of the plant. On examination it was found that a large portion of them had formed with a cotton seed as the nucleus. This seed had apparently been in the car in which the filter sand was loaded. Others were flat or almond shaped. The former was found to a depth of 20 in. in the sand, while the latter remained on the top of the bed. They were removed by fishing the beds with wire mesh scoops while wash water was applied at a rate just sufficient to expand the sand. Their appearance was not noted again, to any extent, until November, 1928, when, following a period of slimy turbidity, they were found in all beds. Extra backwashing and fishing with the wire mesh scoops kept them under control and they disappeared early in December. These formations have never been larger than a good sized bean and have been in evidence only twice in three years.

The Sand.—Some shrinkage from the side and end walls has been observed. The average width of the crack is ⅜ in. and it reached a depth of 2 to 3 in. During the spring algae periods, this shrinkage increases and a maximum width of ¾ in. with a depth of 6 in. has been observed. A physical examination of the sand in every bed was made in November, 1928. Samples were taken at four depths and the coating on the sand grains was determined from their specific gravity. The curve used in these determinations was developed at the Detroit filtration plant where the S.G. of the dry coating was found to be 2.0. The S.G. of the dry clean sand is 2.65.

A storage capacity of 2.3 m.g. is afforded in the clear well and reservoir. This represents a supply sufficient to meet the demands of these communities for a maximum period of 7 hours and a minimum, assuming a demand at a rate of 20 M.G.D., of 2 hours and 50 minutes. The reservoir is 11 ft. deep and the minimum working level permitted is 9 ft. 6 in. The average depth maintained is 10 ft. 3 in.

Raw turbidities have ranged from a minimum of 5 P.P.M. to a maximum of 800 P.P.M. The maximum monthly average in 1928, was 125 P.P.M. and the average for the year was 30 P.P.M. The filtered water is checked for turbidity at least six times daily, using a Baylis Turbidimeter. A maximum of 1.0 P.P.M. was present for a few days in 1928 in the effluent, while the average recorded was 0.3 P.P.M.

Rate of Flow.—The rate of flow through the filter beds is governed by three factors: the demand being made upon the plant, the filtering efficiency of the beds and the filter maintenance programme. A filter rate is maintained which will bring all beds into service during the peak hours of the day. Rates are not changed daily. The rates employed in 1928, expressed in terms of Millions of Imperial Gallons per acre per day, ranged from a minimum of 99.6 to a maximum of 118.5, with an average throughout the year of 112.07.

Laboratory control is exercised over all operations in the plant. The raw and applied water are examined for turbidity every 2 hours and the alum dosage changed as required.

Laboratory Control.—Samples of raw and filtered water are collected 5 times daily for bacteriological analysis and colony counts are recorded which develop on agar plates at 37°C. in 24 hours. The average raw water developed 39 colonies per 1 cc. and the filtered water 6 colonies per 1 cc., showing a removal of 85 per cent B. Coli—aerogenes isolations are made following "Standard Method" procedure, using Lactose broth fermentation tubes and Eosine Methylene Agar for confirmation. The results are expressed in term of "Most probable number per 100 cc." The maximum B. Coli content of the raw water has occurred in April when 117.4 colonies per 100 cc. were found. A minimum of 4.99 was recorded in June, while the average for 1928 was 50.44. The average number found in the filtered water was 1.59, with a maximum of 2.39 and a minimum of 0.98, with an average removal of 96.8 per cent.

Air and water temperatures are recorded every 2 hours and the wind direction is noted at these times. It is known that the velocity and direction of the wind have a definite bearing on raw water turbidities during the spring, summer and autumn seasons. It is thus possible to anticipate plant conditions some hours in advance.

Early in 1929 daily examinations of the raw water were begun to determine plankton content. It is expected that a relationship between these findings and the service hours of the filters will be ascertained when sufficient records are available for study. This will provide additional means of determining coagulant dosages. In the three months period in which these examinations have been made, no members of the plankton families, not common in the Great Lakes water, have been identified. Microcystis (Cyanophyciae) appear frequently and represent from 20 per cent to 50 per cent of the total daily counts.

Records.—Daily records are kept of every operation carried on in the various departments of the filtration plant. In the low lift pumping station the rate at which the raw water is being pumped to the coagulation basins and the total gallons pumped are recorded each hour. The total gallons of wash water delivered to the filter beds are also recorded. The power used by the various pumping units and the total power consumption of the plant is recorded once daily. The total hours in service of every unit in the pumping station are logged on the daily report form.

In the filter building all meters, loss of head and rate of flow gauges are read and recorded every hour. The depth of water in the filtered water reservoir is recorded hourly. These daily records are summarized each month and they in turn are built into an annual report. A plant diary provides a permanent record of items of ordinary or unusual interest and constitute a permanent plant history. All gauges and indicating or recording devices are kept in working order at all times and the utmost care is taken to ensure knowledge, if not control, of every operation attempted. One employee is constantly engaged on plant maintenance and it is rarely necessary to place any unit out of service except for inspection or maintenance.

The plant is electrically operated with power supplied by the Hydro Electric Power Commission of Ontario. The rates are $1.00 per H.P. per month based on the peak load, 2¼ ct. per K.W. for the first 50 hours 1½ ct. for the second 50 hours and .33 ct. for all additional power.

Operating Cost.—Operating costs, divided into five major divisions, i.e. salaries, power, overhead, coagulants and maintenance, totalled $12.58 per M.G. filtered.

The average cost of coagulants per M.G. was $2.09, which included the added cost of "Lime and Iron" coagulation. During the period when "Lime and Iron" coagulation was employed, the average cost per M.G. was $4.09. Alum coagulation during the balance of the year represented an average charge of $1.71 per M.G. filtered.

Salaries represented $4.28 of this sum, Power $2.74, Overhead $2.33, coagulants $2.09 and maintenance $1.24.

The operating staff includes a superintendent, a chief operating engineer, a chief filter operator, three operating engineers, two filter operators and a utility man. The lowest wage paid is 62½ ct. per hour.

The total power consumption for 1928 was 1,455,000 K.W. Hrs., costing an average of 0.82 ct. per K.W. Hr. The pumping cost for power alone, exclusive of wash water, average $2.55 per M.G. or 6.7 ct. to raise 1 M.G. 1 ft.

Overhead charged include supervision, rentals paid for use of railway right-of-way, taxes and insurance. A depreciation reserve of $3,000 is set aside annually to replace the heating system, motors and pumps which will

need replacement within the 30 year life of the debentures.

Maintenance charges include the general upkeep of machinery, buildings and grounds and the purchase of miscellaneous supplies required in this work. The grounds are attractively maintained as water works plants should be. Acknowledgment is made to G. H. Strickland, plant superintendent, for much of the information contained in this paper.

Acknowledgment.—The foregoing is an abstract of a paper presented at the 49th Annual Convention of the American Water Works Association.

Fibrated Asphalt Planking Waterproofing Floor Construction on LaSalle St. Bridge, Chicago

Of late years a great deal of attention has been directed by engineers to some vital requirements in the construction of floors and of the waterproofing course, on both fixed and movable bridges and on the approaches to such structures.

In the specification of materials entering into the construction of the La Salle St. bridge, Chicago, and the approaches to it, considerable attention was devoted on the part of engineers to the requirements of this particular structure—first, as relating to the waterproofing, and second, relating to the wearing surface on the bridge itself.

The illustration, Fig. 1, is of the north approach to the bridge, and the picture shows a crew installing the fibrated bituminous waterproofing planks of the Servicised Products Corporation, Chicago, directly over the waterproofing fabric itself. On the deck pictured, 14,000 sq. ft. of fibrated asphalt sheets, 24x36 in., were laid as a protection to the waterproofing. The waterproofing fabric was laid over the concrete, and while the asphalt was still in a plastic condition, the waterproofing fibrated asphalt planks were placed in position. The granite block paving for the bridge approach was laid immediately over the waterproofing protection course.

The preformed fibrated bituminous sheets provide a blanket of tough, resilient material over the waterproofing, which reinforces the waterproofing itself by increasing its thickness or body, and so protects it from direct damage. It is claimed that due to the fibrous nature, toughness, high tensile strength and the inherent waterproofing qualities of the protection course, the integrity of the waterproofing is maintained indefinitely, regardless of shock and vibration from traffic, the condition of the weather or the state of the temperature.

Its use prevents leaks through the structure, as the greater the pressure upon it, the tighter the waterproofing becomes. The material is sufficiently strong and tough so that it bears the usual loads without distortion.

The very quality of resiliency and toughness enables it to give and take the movements of the main structure. Such a waterproofing course has also some of the qualities of an expansion joint in that it is unaffected by extremes of temperature.

Figure 2 shows Servicised fibrated asphalt plank being installed on the south leaf of the La Salle St. bridge.

The outstanding feature of fibrated asphalt planking is its adaptability to any particular surfacing requirement. The composition of the material can be varied to meet the practical necessities in each case. Fibrated bridge flooring material is constructed of asphalt saturated felt and asbestos fibre for binding, and of asphalts thoroughly mixed with fine mineral matter for compressive strength, and for increasing the abrasive and wearing qualities.

To increase the tensile strength, mats of irregularly overlapping fibre are introduced and further resiliency is effected by inserting divided fibre between the spaces or mats of the linear fibre.

Fig. 2—Servicised Fibrated Asphalt Planking Being Installed on the South Lift of the La Salle St. Bridge, Chicago

When the material is finally incorporated by pressure, into a block-like structure, it is then a composition of extreme toughness, highly resistent to wear and at the same time, extremely resilient and accommodating itself easily to the expansion and contraction movements of the bridge structure.

It is easily laid, in fact just as easily handled as wood planking. There is no difficulty in using the material any time of the year in any climate and without especially trained labor.

Streets and Sidewalks at Boston, Mass.—Boston has a total of 626 miles of roads. The total area of the streets is 11,919,844 sq. yd. The average width of street is 48 ft., the average width of roadway 32 ft., sidewalks 8 ft., residential streets 40 ft., residential roadways 26 ft., and sidewalks 7 ft. The width of boulevards varies from 100 ft. to 200 ft., with roadway width from 25 ft. to 43 ft. The sidewalk widths range from 12½ ft. to 25 ft. The park strips range from 25 ft. to 100 ft. The width of thoroughfares is from 60 ft. to 122 ft., with a roadway from 40 ft. to 92 ft. Sidewalks range in width from 8 ft. to 20 ft.

Electrically Welded Pipe Line for Springfield, Massachusetts

Process Employed in Fabricating Proven Mountain Line

By S. MARTIN, JR.
Industrial Engineering Department, General Electric Co., Schenectady, N. Y.

THE pipe for the Springfield water line was made in 30 ft. lengths from two 30 ft. plates which were bent into half circles and automatically arc welded together. Some consideration was given to welding of the girth joints in the field, but because of considerable opposition, it was decided not to do this on this particular job, and the 30 ft. sections were riveted together in the field. To provide for this, the plates were sheared so that the pipe diameter increased slightly from one end to the other, thereby permitting the small end of one section to fit into the large end of the next section an amount required for the riveted joint.

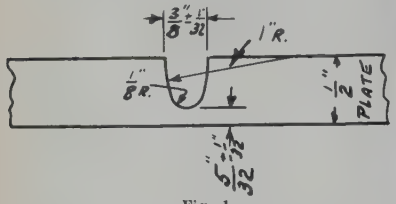

Fig. 1

The first operation in the manufacture of the pipe after the flat plates had been sheared to size was to bevel the sides accurately as shown on Fig. 1. This is done simultaneously on two plates on the plate planer, as shown in Fig. 3. On each plate two lines were then scribed, parallel to the upper edge of the bevel and ¾ in. from it.

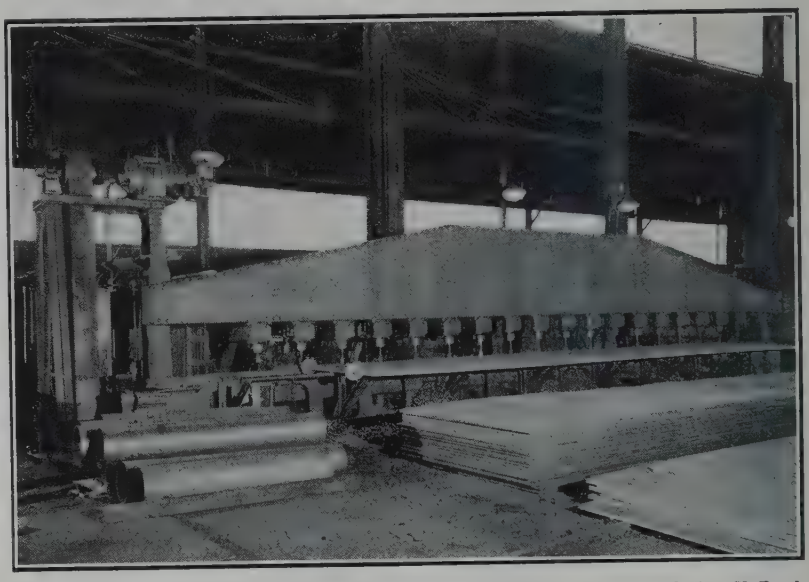

Fig. 3—36-Ft. Planer with Two 30-Ft. Pipe Plates Clamped in Position for Planing U Bevel Preparatory to Rolling and Welding

The plate was then taken to the bending rolls, and by means of a special jig, the 30 ft. edges were bent to the proper radius. The whole section was then formed into a true half circle. Next the two halves of the pipe were placed in a specially designed frame, Fig. 5, and tack welded together approximately every 16 in. on the inside, by hand. The pipe section was then removed and a complete bead run inside by hand. It is then ready to be placed in the welding machine as shown in Fig. 6.

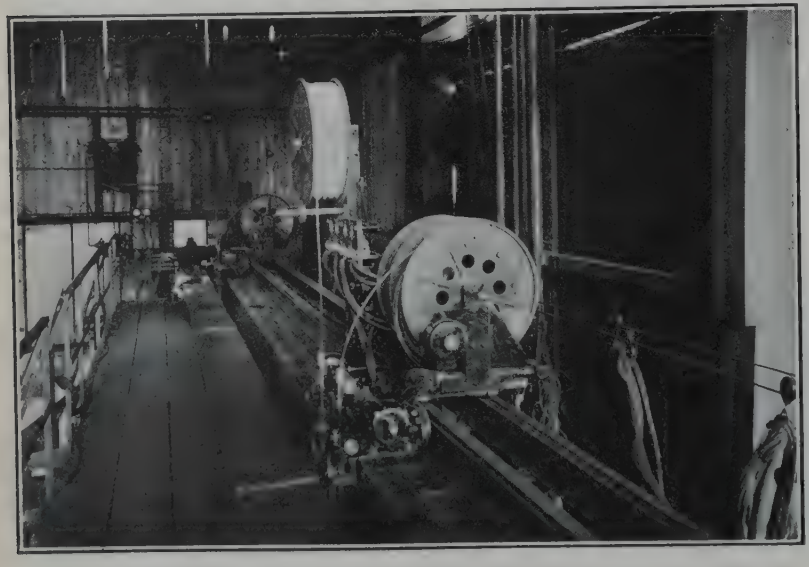

Fig. 2—Two Multiple Arc Welders with Travel Carriages Mounted on 36-Ft. Pipe Welding Machine

Pipe Welding Machine.—The pipe welding machine consisted essentially of three horizontal beams, two above and one below. Enclosed in the lower beam and extending throughout its full length were several sections of fire hose to which compressed air was admitted. On the hose rested a series of plungers, which is turn supported a "backing bar," the latter being fitted with a flat copper chill bar approximately 2 in. wide. Application of compressed air caused the hose to expand, thereby raising the plungers and the copper strip in the backing bar was pushed up against the under side of the joint at a pressure of 200 lb. or more per running inch. The backing bar was also provided with an insulated conductor which formed part of the return circuit for the welding current. By shunting the proper cur-

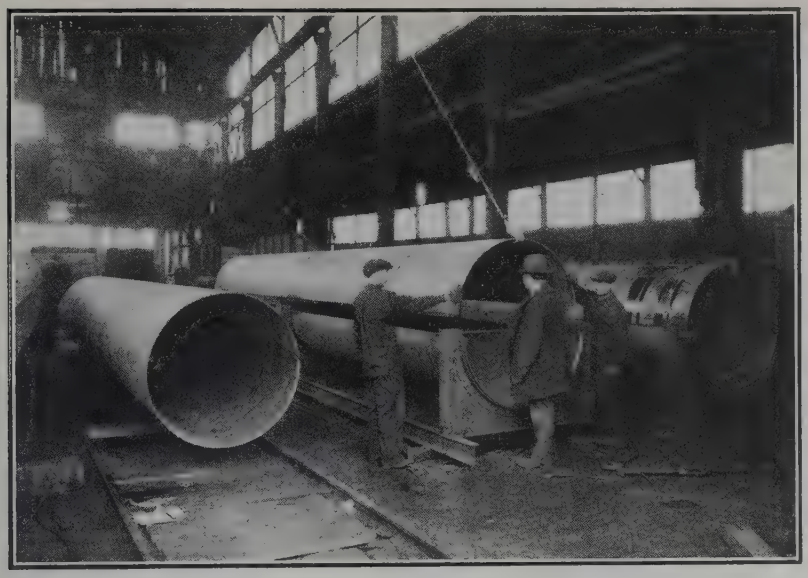

Fig 5—Assembling by Tack Welding Two Halves of a 30-Ft. by 48-In. Diameter Pipe Before Going to Automatic Welder

rent through this bar when the pipe was being welded, the magnetic disturbances of the arc were very effectively controlled.

To the lower side of the upper beams of the machine were attached two copper jaws spaced approximately 2 in. apart and the pipe was placed in the machine so that the joint to be welded was located centrally between these two copper jaws and directly over the copper strip in the backing bar.

Figure 2 shows the double head automatic travel carriage for the welding after the plates have been properly clamped in the welding machine. Two such carriages were mounted on the 30-ft. machine. This meant that each one of these did 15 ft. of pipe and reduced the welding time to 50 per cent of that required for one carriage. A third such double head travel carriage is being contemplated for a further saving of welding time on future operations.

After one seam was welded, the pneumatic clamp was released and the pipe rotated to bring the second joint in position.

Speed of Welding—Electrode-Power Consumption.—The speed of welding attained by the multiple arc process with two welding heads on ½-in. plate was approximately 28 ft. per hour. Using the welding conditions formerly outlined, about 1 lb. of electrode was deposited. The current for each pair of welding heads was supplied from a 1,000 ampere-1 hour rated constant potential welding generator driven by an induction motor. The power consumed was approximately 2.15 kw.-hr. per foot of weld on ½-in. thick plate.

Testing.—At the request of the inspector, check test plates about 12 in. long and a total width of 16 in., with a bevel as specified for the pipe joints, were placed at each end of the pipe seam and welded under the same conditions as the pipe itself. These plates were then cut into specimens. Some of these were tested in tension, others bent and still others were put in a fatigue testing machine.

The pipe itself was given a thorough visual inspection to determine possibility of holes, lack of fusion and reinforcement. The weld was reinforced—i. e., its height above the surface of the plate was usually from 1/16 to ⅛ in. The minimum and maximum values permitted by good practice are 1/32 and 3/16 in. respectively. The weld bead must also be central between the scribed lines on the plate at each end of the joint, allowing a maximum variation of 1/16 in. from the center. The width of the weld bead was measured and its over-all width was not permitted to be less than 9/16 in. Any holes which were seen on the top surface of the deposited metal were carefully chipped and if they extended below the surface of the plate, the spot was rewelded by hand. The edges of the bead were also examined to see that the weld metal was thoroughly fused along the top of the plate. Any cracks or hollow spots were chipped and rewelded by hand.

After the welded pipe had been given a careful visual inspection and any defects rewelded, it was placed in the testing machine, Fig. 7, and subjected to the following hydro-static pressures in pounds per square inch:

Thickness of Pipe in In.	5/16	⅜	7/16	½
66-in. pipe	....	160	....	....
54-in. pipe	135	160	187	213
48-in. pipe	....	....	210	240
36-in. pipe	....	....	....	320

In this particular installation the rivet holes were then punched in each end of the pipe, after which it was thoroughly cleaned and dipped vertically in an electrically heated tank of coal tar pitch varnish (Fig. 8). The pipe was submerged in the bath long

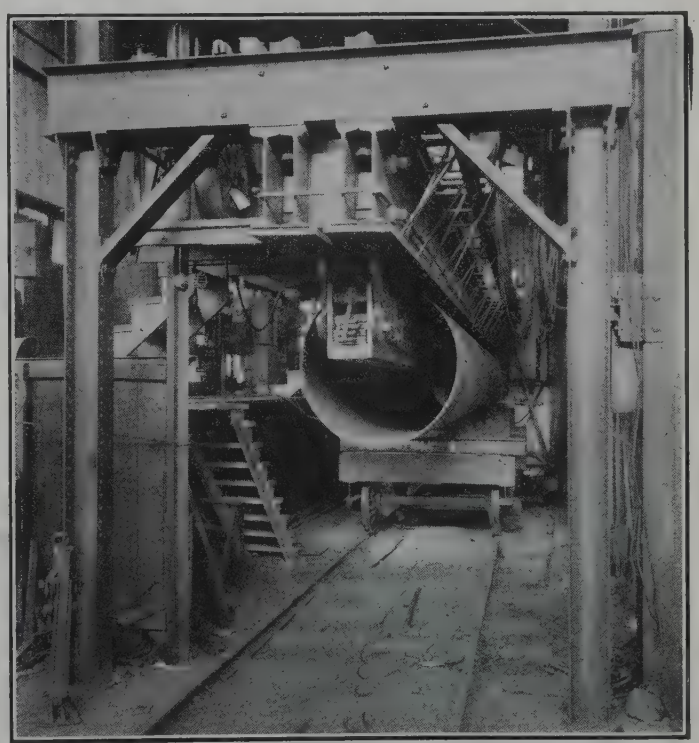

Fig. 6—Loading End of 36-Ft. Pipe Welding Machine Shows Lower Supporting and Pneumatically Operated Backing Up Beam Locked in Position for Welding

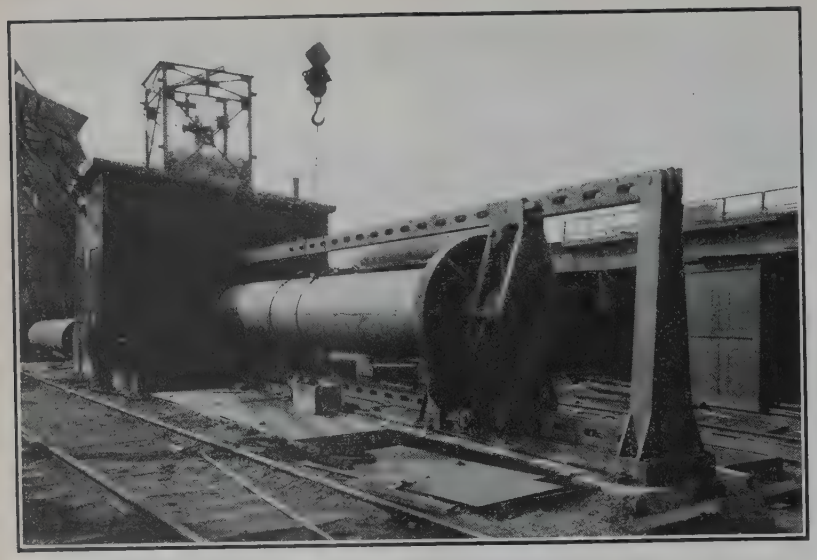

Fig. 7—Hydraulic Testing Machine with 30-Ft. Long, 48-In. Diameter Pipe in Place

enough to heat the metal uniformly to the temperature of the bath. It was then removed and suspended in a vertical position until the coating had drained and set.

Acknowledgment.—The above is abstracted from a paper presented at the 49th annual convention of the American Water Works Association.

Water Rates

In the sale of any commodity, and water is a commodity, there must be in all fairness some basic principle upon which its cost of production and sale can be established, so that each individual may receive equitable results. In other words, the cost of service is made the legal basis for rates. To determine upon a rate which is fair and equitable, both to the consumer and to the water department, demands a consideration of all the factors which enter into the operation of the plant. These may be designated and grouped to meet requirements of the individual plant and existing conditions. The practice of determining rates by comparison with other cities is a false standard.

Water rates should be based upon the cost of production. A very important element is the value of the property that is rendering service. In order to render good service, the utility must be financially sound. It has been my observation that financially poor utilities and poor service go hand in hand. The rate charged must be sufficient to meet all fixed charges, otherwise the utility cannot function on a sound financial basis. Our rates are just, fair and reasonable, and are based upon the cost of the finished product, without regard in any way whatever to the rates in vogue in any other city, whether higher or lower.—Extract from 1928 annual report of W. H. Lawrence, Superintendent of Water Works, Kalispel, Mont.

Municipal Garbage Removal Governmental Function

The Supreme Court of Appeals of Virginia, in a decision rendered March 21, 1929, in the case of Asbury v. City of Norfolk (147 S. E. 223), held that garbage removal by the city was a governmental function. The decision is reported as follows in Public Health Reports May 31, 1929:

An action was brought against the city of Norfolk because of personal injury to plaintiff caused by being struck by a runaway horse which had been hitched to a wagon being used at the time in the removal of garbage. The question which was before the Supreme Court of Appeals was whether, in the removal of garbage, the city was acting in a governmental capacity and was thus relieved from liability for negligence. The holding was that garbage removal by a city was a public governmental function, as contrasted with a corporate or private function, and that the city was not liable. In deciding the matter the court said that "There is some conflict in the cases, but the weight of authority quite certainly is to the effect that the removal of garbage by a municipality is a governmental function, which is designed primarily to promote public health and comfort, and hence that the municipality is not liable therefore in tort when the negligence which is charged occurred in the performance of that particular function, and no nuisance is thereby created."

Financing the Operation and Maintenance of Sewage Treatment Plants

How This Important Problem Is Handled in Various States

By EARNEST BOYCE
Chief Engineer, Kansas State Board of Health, Lawrence, Kan.

THOSE interested in the problem of adequate sewage disposal are constantly confronted with the fact that sewage disposal plants built to accomplish the destruction of the objectionable characteristics of sewage wastes are, after being built, frequently not operated so as to obtain the results expected. While many plants are given good supervision, in at least the average plant the operation must be considered as being the minimum attention that the city can give and yet avoid damage claims due to faulty operation. Governing bodies are usually willing to provide adequate funds for city departments when the expenditure is demanded and expected by the taxpayer of the city, but it is hard with the many demands made on a city's financial resources for a governing body to provide funds to dispose of sewage wastes after they are conveyed to a point where they will not annoy the residents of the city.

The demand for the installation of sewage treatment works and later for their efficient operation comes in most cases not so much from a sense of civic responsibility as from demands by damaged property owners with threatened suits or from some state supervisory authority—usually the State Department of Health. Consequently, a city is quite apt to adopt, or rather lapse into a policy of doing only that which is definitely required. A sewage disposal plan may be considered as manufacturing a product of little or no value out of a waste material which, before this process existed, was a definite liability. No revenues are produced that in any way equal the expense, consequently the cost of the plant and its operation must be paid out of benefits that accrue from the removal of the liability represented by the untreated sewage waste.

The most common place to carry the cost of sewage treatment is to include it in the general tax levy. There is some reason to consider this as a just and proper place for the charge. But funds must be available and the proper appropriations secured in competition with many other demands.

Sewer Service Charge.—If we consider that a system of sewerage exists only to give service to those contributing sewage wastes, then we should properly classify this municipal improvement with other public utilities and expect that all charges for capital and operating costs be paid by those who are served. This view has been reflected in recent legislation in several states where provision is made by statute for the charging of sewer rentals. There are some who feel that a sewer is not properly a public utility but rather a necessity from the standpoint of public health and being necessary to the health and well-being of the community should be paid for by the community as a whole. When an individual makes use of a public utility, such as telephone, electricity, gas, or water, he is primarily interested in the service given by such a utility. A person not interested in having this service is at liberty to do without it. While it may inconvenience others, his unwillingness to have the utility does not create any hazard for his neighbors. With the sewer, it is different. It is important that all and not a part of the sewage wastes be removed from the city. The poorest as well as the most expensive property should be given service,—in fact, not infrequently it is necessary to require in the interest of better sanitation that sewer connections be made against the property owner's will. Such procedure would be unheard of with any other utility. It is more nearly comparable with fire protection service. This comparison might be carried further. We divide our public water supply costs and charge fire protection costs to general taxation and the costs of water supply service to the consumer, in proportion to the use he makes of this utility. It would seem that the principle that has been followed in the past of paying for sewers and sewage disposal improvements by general tax levy is a sound one, but it may be that after the community has, as a whole, provided this service, it is proper that those who use the sewers should pay for their maintenance and operation, and possibly in approximate proportion to the amount of such use.

The cost of sewage treatment was formerly principally one of first cost with a very small item, proportionally, of maintenance. At present, where modern sewage disposal is provided or where all or a part of the sewage must be pumped, there is an annual charge that must in some way be carried in the budget of the city. The service has undoubtedly gone beyond where all the expense should be considered as incurred in the interest of sanitation alone.

If charges are made against the use of the service rendered by a system of sewerage, there remains the problem of deciding how these charges should be apportioned. It has been suggested that since sewers primarily serve the purpose of removing the city water after it has been used, the amount of water used is a measure of the use made of the sewer and might give a rational basis for rental or service charges.

How the Ohio Rental Law Works.—The subject of sewer service charges as a means of financing sewerage and sewage treatment was given consideration by a committee on sewage treatment at the Conference of State Sanitary Engineers. It was considered as one of the three main items to be considered in 1928 by the committee, the other two being, first, a study of progress in establishing technical operation of treatment works and, second, continued sewage treatment research. The operation of the Ohio sewer rental law enacted in 1923 was discussed in detail in their report as follows:

"It is well to review briefly the sewer rental situation in Ohio. Seventeen municipalities are now financing their sewerage and sewage treatment works either in whole or in part out of moneys collected from sewer rentals. The smallest municipality in this list has a population of less than 600 and the largest over 150,000. The charges average about $4 per sewer connection per year, although they vary from $1 to $8 annually. Payment is usually made upon the quarterly plan. The manner in which the charges are made vary. The number of municipalities basing the charges upon the volume of water consumed (5) about equals the number making a flat rate single charge per sewer connection (4). A flat rate according to the number of fixtures is employed by two; and two others have a flat rate schedule per connection according to the character of the premises served. Variations in amounts of charges are on account of the variations in size of the municipalities, and the differences in amounts of funds attempting to be secured. For example, the $4 annual charge at Delaware (8,576) is planned to meet expenses of maintenance, operation, etc., but not to meet sinking fund charges on the new plant. In order to include a substan-

tial portion of the sinking fund or replacement charges, the small city of Kenmore (12,683) charges $8.

"There seems to be a well defined trend in Ohio and elsewhere to adopt the rental or utility idea of financing sewerage works maintenance and operation. Experience indicates that such a plan is most favorably considered and is easy to place in operation wherever a new sewage treatment works is being installed or a complete renovation being given to an old treatment plant."

From other references, we find that the estimated revenue from sewer rentals at Delaware, O., will amount to $11,000 per year. It is estimated that this will be sufficient to maintain and operate the treatment works, and the sewerage system as well. It will also carry the clerical cost necessary for collection. Sewage pumping is necessary and the sewage is treated by passing it through an Imhoff tank and sprinkling filters.

The North Carolina Law.—The Sessions Laws of North Carolina for 1927 provide for the creation and maintenance of sanitary districts. Section 20 of that law is interesting in that it covers service charges and rates in the following words:

"A sanitary district board shall immediately upon the placing into service of any of its works apply service charges and rates which shall, as nearly as practicable, be based upon the exact benefits derived. Such service charges and rates shall be sufficient to provide funds for the proper maintenance, adequate depreciation, and operation of the work of the district. Any surplus from operating revenues shall be set aside as a separate fund to be applied to the payment of interest on bonds, to the retirement of bonds, or both. As the necessity arises the sanitary district board may modify and adjust such service charges and rates from time to time."

The Michigan Law.—Michigan statutes provide that a city may, by charter, acquire, establish, operate, extend and maintain sewage disposal plants, sewers and plants, either within or without the corporate limits of the city, as a utility, including the fixing and collecting of charges for service covering the cost of such service, the proceeds whereof shall be exclusively used for the purpose of city sewage disposal system to include a return on the fair value of the property devoted to such service, excluding from such valuations such portions of the system as may have been paid for by special assessments.

In act 320, Michigan Statutes 1927, a portion of Section 2 reads as follows:

"Such sewage disposal plant and system shall be considered a public utility within the meaning of any constitutional or statutory provision of this state for the purpose of purchasing, owning, operating, constructing and equipping such sewage disposal plant and system."

Section 2 further provides that a municipality may issue bonds beyond the general limits of the bonded indebtedness providing such bonds shall not impose any general liability upon the municipality but shall be secured by revenues from the operation of the system of sewerage. It likewise provides that the system of sewerage may be taken over and operated under a franchise as a security provision for bonds.

Section 3 provides:

"The legislative body may establish just and equitable rates or charges to be paid to it for the use of such sewage disposal plant and system by each person, firm or corporation whose premises are served thereby."

The Provision in Pennsylvania.—In the 1927 Session Laws of Pennsylvania, Section 2170 to 2173, inclusive, the following provision is made for the assessment of cost of maintenance and repair:

"Whenever any borough has constructed any sewer or sewer system, or has acquired wholly or partially the same at public expense, the council of such borough may provide, by ordinance, for the collection of an annual rental or charge, for the use of such sewer or sewer system, from the owner of property served by it. The council may, at its discretion, in lieu of such annual rental or charge, provide for the payment by such owner of a fixed sum.

"Such annual rental shall not exceed the amount expended annually by the borough in the maintenance, repair, alteration, inspection, depreciation, or other expense, in relation to such sewer or sewer system, and may include any interest on money expended by the borough in the construction of the sewer or sewer system. The said annual or fixed sum shall be apportioned equitably among the several properties served by the said sewers.

"Such annual rental or charge, or such fixed sum, shall be authorized and collected as provided by general ordinances, and, when so levied and charged, shall be a lien on the properties charged. The collection thereof shall be made and enforced in the manner municipal claims are now or may hereafter be collected.

"The councils of such borough shall execute a warrant or warrants, authorizing the collection of such annual sewer rentals or charges, or such fixed sum, to the officer employed by council to collect the same. Such officer shall have the authority now vested by law for the collection of borough taxes.

"Such annual sewer rentals or charges, or such fixed sum, shall be a lien on the properties charged with the payment thereof, from the date set forth in the ordinance, and, if not paid after thirty days' notice, may be collected by an action of assumpsit, in the name of the borough against the owner of the property charged, or by distress of personal property on the premises, or by a lien filed in the nature of a municipal lien."

The Kansas Law.—A statute may provide that special levies may be made for maintenance and operation. For example, the Kansas law in Section 12-630, Revised Statutes of 1923, provides as follows:

"Levies for sewage disposal plants. That all cities of less than 50,000 in the state of Kansas be and are hereby authorized to levy a tax, in addition to all other taxes allowed by law, not exceeding one-half mill on the dollar upon all taxable property in such cities, to be collected as other taxes and used for the purpose of maintaining and operating sewage disposal plants. Such levy shall not prevent the use of other funds available for the same purpose."

We believe that in the future more thought will be given to the matter of providing adequate operating revenues and that some sort of service charge will be more generally adopted as being an equitable method of providing these revenues.

Advantages of Service Charge.—One of the principal advantages that we see in the application of a service charge is that funds can be provided continuously without the necessity of an annual appropriation. A source of revenue is provided that does not come in direct competition with other budget items that must be included in the tax levy. This is important because the public, as we suggested in the beginning of this paper, are not usually as much interested in matters pertaining to sewage disposal as they are in other budget items and when an economy cut is made in the tax levy or funds are needed elsewhere, sewage disposal operating funds are either forgotten or so reduced as to make efficient operation impossible.

This subject is one to which we should give further thought. It is somewhat removed from the design problem that we usually consider, but fully as important. Design without adequate operation is valueless, and a sewage disposal plant that is operated only when funds happen to be available cannot be depended upon to accomplish the purpose for which it was built.

Acknowledgment.—The above paper was presented at the 9th Iowa Sewage Treatment Conference, held at Ames, Ia.

Sidewalk Zoning.—A new plan for zoning sidewalks has been put into effect by the city of Detroit, Mich. Sidewalks on the chief shopping avenue are marked off into three lanes—one for northbound pedestrians, one for southbound, and an inside lane where window-shoppers can loiter as much as they like. At street intersections painted foot-prints direct people into the right lane of traffic. The plan was first installed for the Christmas shopping season, and met with such success that it is to be adopted permanently.

Zeolite Softening Plant Operating Experiences

Data on Plants of Ohio Valley Water Co. and Sewickley, Pa.

By D. E. DAVIS and J. T. CAMPBELL
Of the J. N. Chester Engineers, Pittsburgh, Pa.

THE data and comparisons herewith have to do with the 4,000,000 gal. pressure type softeners at the plant of the Ohio Valley Water Co. about six miles below Pittsburgh, Pa., and the 2,000,000 gal. open-softener type plant for the Borough of Sewickley, Pa.

Salient Features of Plants.—The salient features and contrasts are briefly summarized in Table I:

The distinguishing differences between the two plants reside in the contrasts between pressure and open type units. The open softeners at Sewickley, being designed for use as filters as well as softeners, operate at usual filtration rates and correspond closely to rapid sand filtration practice as regards head losses, sand rise, etc. The pressure type softeners at the Ohio Valley Water Co. operate at about twice the rate of the open filters, but require materially greater head in the ratio of 32 ft. to 5 ft. The open units permit of ready and continuous observation of the process, which is difficult of accomplishment in the closed units, because of the design.

A wash rate up to 13 gal. per sq. ft. per min. is possible without loss of sand on the open units, although (with the clear water handled) the rate of 7 gal. is found satisfactory. The closed type units have shown considerable losses at the recommended 6 gal. rating, and have given some trouble at four. This is probably due to the fact that their circular cross-section, and cost considerations on the shell limits

View of 2,000,000 Gal. Water Softening Plant of Sewickley, Pa.

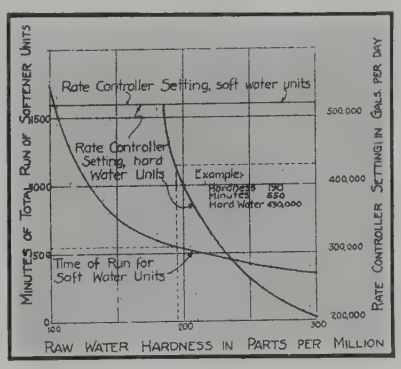

Fig. 2—Curves for Control of Operations

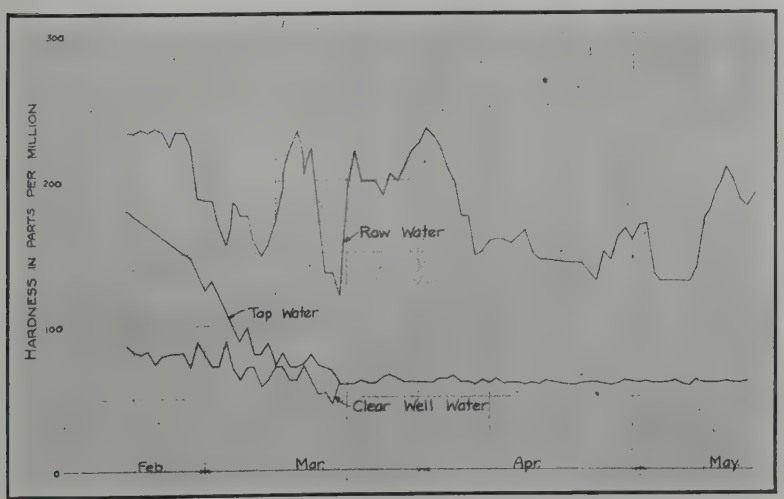

Fig. 1—Operating Results in Terms of Hardness

the distance above the sand line at which the off-take pipe (corresponding to wash trough) can be placed. As the wash water rises it is compelled to converge toward the center at the upper segment of the circular cross-section, thus relatively increasing the velocities. This fact together with the short distance between sand and off-take limits the wash rate and evidently makes it difficult to prevent some loss of sand. Experience thus far with the open units indicates that this difficulty has been obviated in that design, since no losses can be detected.

The sand cross-section in the open unit is rectangular, which is not quite true of the circular closed unit. Standard rate controllers are used on the open unit, whereas the closed unit passes the quantities which the available head loss imposes. In these two features, the open filter appears to advantage, in that the water (and brine solution) seems to travel with greater uniformity downward through the sand thus assuring the fullest regeneration of each sand particle and the maximum removal of hardness per cu. ft. of sand.

Operating Results at Sewickley.—The graph in Fig. 1 presents operating results since the Sewickley plant was started. The hardness of the water reaching the consumers was reduced gradually down to 60 p.p.m. at which figure it has been maintained. This was accomplished by gradually softening the several days' reserve in the borough reservoirs. There was evidently no difference in the taste between the hard and soft water—at least no general comment has been voiced. Some complaints were expected, either for imaginary or real reasons; and ac-

cordingly precautions were taken for making daily bacteriological and chemical analyses on samples taken in the process steps from the crib through to the reservoir. So far as known, not a single complaint was made.

The plant has proved to be quite simple and fool-proof in operation. The zeolite filters are set at a constant rate of about 2 gal. per sq. ft. per min. while the hard water filter is set at the approximate rate shown in the curve of Fig. 2. The second curve indicates the period of run, and by following the procedure there set out, the final product is kept close to 60 p.p.m as may be seen in Fig. 1.

The individual operation consists in turning the effluent of the newly regenerated softener into the soft water clear well, from which it proceeds to the mixed water clear well, there mingling with the hard water effluent from the hard water clear well. The operator usually checks (by soap method) and records the end of the soft water run, and of the "Twilight Zone" or period during which the zeolite bed completes its exhaustion of sodium, and the hardness changes from zero to that of the raw water. The latter part of the entire run usually involves the delivery of hard water through the bed. The operator finishes the total run by closing the raw water valve, and pulling the water to within an inch or so of the sand. He then closes the effluent valve, presses the button to start the brine pump which delivers the brine solution over the bed, and then opens the rewash valve to a calibrated point so as to pull the brine down through the zeolite sand at a rate from 1.5 to 2.0 gal. per sq. ft. per min. After the brine solution approaches the sand line, the

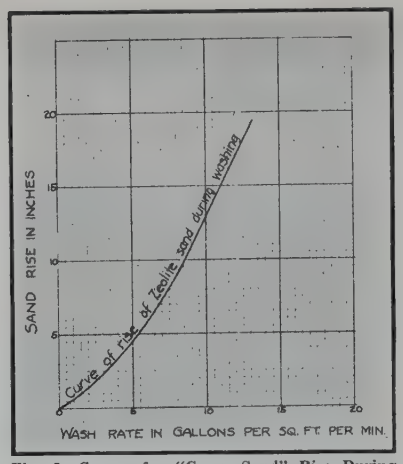

Fig. 3—Curves for "Green Sand" Rise During Back-Washing Operation. Sand: Effective Size .285 mm.; Uniformly Coeff. 1.50

rewash valve is fully opened (to about a 3.2 gal. per sq. ft. per min. rate), and also the influent valve.

During this period of "rinsing" the waste chlorides are washed out to waste through the sewer. After a total elapsed period of approximately 35 minutes, the rinsing is pronounced complete, as determined by tests explained in Fig. 4, and the softener is started on another cycle.

Units have been back-washed on an average of once in 71 hours of service during which period the head on the softener units increases from 4.8 at the start to 7.2 at the end, contrasted to 2.9 and 6.4 for the hard water unit.

The record of 15 consecutive runs is shown in Table II:

During an earlier experimentation period the results for 38 observations indicated a removal of 3,790 grains of hardness per cu. ft. of green sand, and the salt dose .353 lb. per 1,000 grains removal.

This improvement has been effected by changing the dilution of the salt dose, while maintaining the same quantity of salt in all cases. In the earlier runs an 8.6 per cent solution (by weight) was employed, whereas the latter regenerations have been made with a 5 per cent solution. The apparent explanation of the result is that the more dilute solution permits the salt to bathe each sand grain for a longer period than is true of the concentrated solution, and induces a more complete exchange of sodium.

Table I

Plant	Ohio Valley Water Co.	Borough of Sewickley, Pa.
Type	Pressure	Open
Number of Units	4	4
Nominal Cap. in Gals. per 24 hours	4,000,000	2,000,000
Area per sand bed in sq. ft.	208	181.5
Cubic Feet of Sand per Unit	670	470
Direction of flow	Downward	Downward

Note: "A" & "B" observations were made on samples taken from the rewash line; the first sample being taken immediately after opening the valve
Rate of increase in hardness during twilight zone "C"
("C" observations began with the last appearance of zero water in the effluent (or the first appearance of hard water))
TIME ELAPSE IN MINUTES AFTER INITIAL OBSERVATION

Fig. 4—Hardness and Chloride Changes During "Rinsing" and "Twilight Zone" Periods

The curve of sand rise for green sand during the washing period (Fig. 3) was obtained by lowering a series of test tubes, spaced at two in. intervals, into the space between the sand line and the wash trough, and noting the rise from the sand line to the highest tube in which the sand appeared for each given rate. The curve seems to correspond closely with other observations on quartz sand of similar grain characteristics.

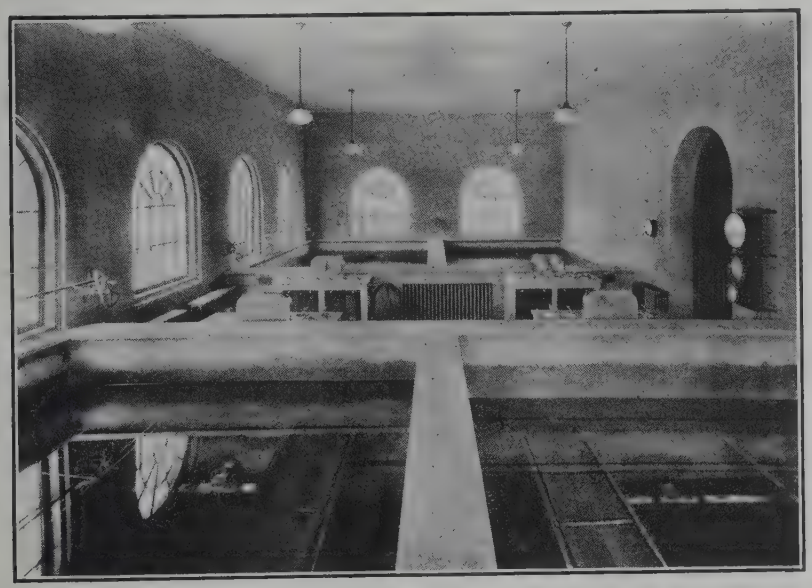
Hardness and Chloride Changes.—Certain technical data respecting the rinsing out of chlorides at the close of the regenerating period and of the action of the zeolite bed towards the end of the softening period are grouped in Fig. 4. At the start of the softening operation the fresh zeolite (or green sand), contains its maximum amount of sodium. As the "hard" water passes through the bed, an ionic exchange takes place through mass action such that the calcium and magnesium in the water "switch partners" with the sodium in the zeolite. For about 90 per

Table II.—Record of 15 Runs on Zeolite Softener Units

	Minimum	Maximum	Average
Hardness of raw water in p.p.m.	185	210	194
Harness of final product in p.p.m.	60	68	63
Length of soft water run in minutes	345	460	398
Length of "twilight zone" in minutes	95	150	123
Length of hard water period in min.	0	60	38
Length of total softener run in min.	495	645	559
Length of regeneration period in min.	20	40	37.7
Hardness removal in grains per cu. ft.	3700	4330	4004
Pounds of salt per 1000 gr. hardness removed	.361	.309	.334

cent of the time until full hardness appears, the bed turns out a water approximating zero hardness. During the latter 10 per cent of the period, or "twilight zone," the water changes from zero to full hardness according to a straight line relationship shown in Curve "C" of Fig. 4.

During the regenerating period there is a reversible reaction, such that the sodium of the brine solution enters the zeolite sand, displacing the calcium and magnesium which are "rinsed" out to the sewer as shown in Curve "A" of Fig. 4. The departure of calcium and magnesium is approximated by Curve "B." The six minute lag between the opening of the rewash valve and the maximum appearance of chlorides represents the waste of water (yet unbrined) which remained in the sand, gravel, etc., when the brine was applied.



Filter and Softening Units of Plant of Sewickley, Pa.

A Correction

In the article on the Design of Sprinkling Filter Distribution Systems published in the June issue there was an error in Formulas No. 1 and 2.

The formulas should read:

$$(1)\quad X=\sqrt{\frac{2(2^2+4^2+6^2\ldots+N^2)}{N}}$$

$$(2)\quad Y=\sqrt{\frac{1^2+2^2+3^2\ldots+N^2}{N}}$$

Sanitary Engineering Courses in the United States

A compilation of data concerning sanitary engineering courses in the colleges of the United States has recently been prepared by the United States Public Health Service. From this summary it appears that there are 16 colleges in the United States at present operating either regular or optional courses in sanitary engineering.

There seems to be considerable difference of opinion among the universities as to the fundamental conception of a sanitary engineering course. The sanitary engineering courses are in reality civil engineering courses with certain appended subjects, such as water supplies, sewage disposal, the bacteriology and chemistry of water and sewage, and a little public health instruction.

Emphasis in both sanitary engineering and public health subjects reflects in practically all the institutions the personality of the professor of sanitary engineering.

The number of sanitary engineering graduates annually is increasing. There is a great variation in the degrees granted by the institutions for equivalent work and also in the names of the courses. In four of the 16 institutions the term of the sanitary engineering courses is either five or six years.

The Model Traffic Ordinance

According to the National Safety Council eleven cities, including Indianapolis; Grand Rapids; Providence; Roanoke, Va.; Port Huron, Mich.; Alton, Ill.; Findlay, Ohio; Boston; Hinton, W. Va.; Fort Dodge, Ia., and Great Falls, Mont., have adopted exactly, or substantially, the Model Traffic Ordinance drawn by the National Conference on Street and Highway Safety. Los Angeles, San Francisco, and Chicago adopted ordinances substantially the same while the model ordinance was in process of formation.

The California Model Ordinance, prepared before and substantially the same as the Model Ordinance, has been adopted by 92 cities in California.

The Michigan Model Ordinance, which is also in substantial agreement with the Model Ordinance, has been adopted by 215 cities and villages in that state.

New Jersey has incorporated most of the provisions of the Model Ordinance in a state law which is thus operative for all municipalities. South Dakota has also adopted Act IV of the Uniform Vehicle Code practically verbatim and this went into effect July 1st for all municipalities in the state.

Municipally-Owned Boiler Plants Must Pay Inspection Fee.—Municipally-owned steam boilers used in plants operated by cities and towns of Arkansas are subject to the payment of the regular inspection fees to the state as are paid by individual owners, it was held in an opinion issued by Attorney General Hal L. Norwood at the request of J. D. Newcomb, chief boiler inspector in the state department of labor. The opinion, which was written by Assistant Attorney General Robert F. Smith, was handed down when the state's right to collect such charges was questioned by Mayor Pat L. Robinson of Little Rock on the contention that the state cannot legally tax one of its political subdivisions. Payment of a bill rendered by the boiler inspection department of the labor department covering inspections of boilers used in Little Rock municipally-owned plants was refused by the city on this interpretation of Act No. 228 of 1927, which requires the inspection of steam boilers within the state as a safety measure. The fees pay the expense of such inspections.

Missouri Valley Water Works to Meet in November.—The 15th annual meeting of the Missouri Valley Section of the American Water Works Association, will be held at Sioux Falls, S. D., on November 6, 7, and 8. R. Rees, Superintendent of the Sioux Falls Water Works, will be in charge of the local arrangements. The office of E. Waterman, the Secretary, is Room 104N, Engineering Building, State University of Iowa, Iowa City, Ia.

Pump Discharge Headers and Pump Piping for Water Works Stations

A Valuable Discussion of a Much Neglected Topic

By F. G. CUNNINGHAM
Of Fuller & McClintock, Engineers, New York City

PROBABLY few important features of water works practice have been so neglected and have been developed in such disregard of sound engineering practice as the piping arrangements used to connect the pumps with the outgoing supply mains, commonly referred to as "header systems." Probably not over one out of ten such systems, as installed, is arranged so as adequately to safeguard reliability of service and obtain maximum reliability consistent with the number of valves and fittings used.

Effect of Local Conditions.—Consideration of this subject in a specific case must take account of varying local conditions that cannot be dealt with in a general discussion such as this. For example, the presence and amount of elevated or hill-top storage beyond the high service pumps has a direct bearing upon the problem. With enough such storage for many days' demand, meager and poorly arranged piping arrangements might still furnish reliable service. Also the number of pumps and of supply mains included in the layout and the number that can be spared without crippling service will influence somewhat the required header arrangements. On the other hand it is obviously unwise deliberately to install header arrangements that might result in shutting down several pumps or several lines even in cases where they might be spared, when a comparatively nominal extra expense or more skill in the arrangement would render such shut-downs unnecessary.

Since most cities have comparatively little or no storage of pressure water, we may assume that for a typical case such storage is absent or too small greatly to be relied upon. Where a considerable amount of it is present the supply that might be obtained from it may be considered in conjunction with that available from the pumping station at the time of the most serious break in the system of header piping, and to that extent might modify the statements about to be made in this paper.

Meeting the Maximum Demand.—Any station should be at least capable of meeting the maximum domestic demand plus fire draft with the largest pump out of service. Preferably this capacity should be available with the two largest pumps out of service, due to the various conditions such as routine repairs, breaks in steam piping or valves or things of that sort to be expected. Most stations have at least one spare pump and many have two, but few have more. Whatever the number of spare units may be, the writer would point out the obvious inconsistency in providing piping arrangements that might readily throw out of service more than the number of pumps that can be spared. It is also desirable and in some cases strictly necessary that full domestic and fire service be maintained with one of the supply mains, or the portion of it necessarily dewatered in repairing any valve, out of service. Considering these factors and the variations in pumping demand normally to be expected, not less than three pumps and three supply mains are required to present an entirely flexible and satisfactory layout for any case where pressure storage is small or absent.

Functions of Good Discharge System.—The functions of a good discharge header may be summarized as follows:

(a) To permit any pump, pipe or valve to be isolated for repairs without crippling service.

(b) To permit any or all pumps to deliver to any or all supply mains, or at least reasonable flexibility in this respect.

(c) To allow of ready operation of essential control valves, especially in emergencies.

(d) To provide convenient access for inspection and repair of control valves and connecting pipes.

(e) To provide reliable and multiple points of connection for essential small water pipes for station service.

The repair or replacement of a valve in a header system is naturally more serious than that of a piece of pipe, since it involves two runs of pipe, that is one on each side of the valve, instead of one run. It is essential, then, to provide two valves between any two adjoining pump connections or supply main connections if it is desired to avoid shutting down more than one unit or line with a single break. With these facts and the above mentioned functions of a good header in mind it is interesting to examine diagrams showing some actual or typical header layouts.

Header Layouts.—Figure 1 shows a flagrant case of poor arrangement actually installed in a recent project. The entire battery of pumps is connected to a single suction main and a single discharge main without valves except on the branch connections to the pumps. The repair of any piece of pipe in suction or discharge lines or of any valve would put the entire station out of service.

Figure 2 shows two pumps and two lines with two valves between pumps. One pump and one line would be shut down by any break or any valve repair. If it were not for the two valves between the pumps the entire station would be shut down. This layout is of interest principally in showing that the number of pumps and of lines is too small.

Figure 3 shows three pumps and two lines of which two pumps and one line would be put out of service by repairs to valves "A" or "B."

Figure 4 shows the same thing except that there are two valves between adjoining pumps making it unnecessary to shut down more thon one pump and one line with a single break.

Fig. 5 shows a three pump layout containing six valves and with a poorly arranged cross connection. Repair to valve "A" would put out of service two pumps and one line. In Fig. 6 is shown a good layout having the same number of pumps, lines and valves, and with each pump discharge split into a separate valved connection leading to each main. With this arrangement the most serious break cannot shut down more than one pump and one supply main, which result would occur through the repair of any one of the six valves. Fig. 7 shows another way of accomplishing the same results as in Fig. 6 and with the same number of valves. The consequences of the most serious valve repair are the same as the Fig. 6, except that the chances of such occurrence are somewhat less since there are only four valves that can produce that result instead of six.

Fig. 8 shows substantially the same arrangement as Fig. 7 except that additional valves are inserted bringing the total number up to 11. Under this arrangement two advantages are gained as compared with the others. First, while the repair of certain valves can shut down either one pump or one supply main, no single repair can shut down both a pump and a supply main. Second, connections are such that there is less likelihood of emergencies re-

quiring the stopping of one pumping unit and the starting of another, which operation might be embarrassing.

Fig. 9 shows the header layout designed by the writer's firm for Memphis, Tenn. The effect of the most serious single break or repair would be to put one pump or one supply main out of service. Due to the arrangement of cross connections it is possible in this layout to continue pumping to all of the mains with all pumps except the one that might be directly affected by a break, thus cutting down the chance of having suddenly to start up a new unit as above mentioned.

Fig. 10 shows a layout devised by the writer in connection with work at Kansas City, Mo. It can be expanded or contracted indefinitely to fit any number of pumps or supply lines. It is founded upon the reasonable basis that one pump and one supply main but not two pumps or two mains may be put out of service simultaneously without impairing service. The features of this arrangement are the way in which the pump discharges and the supply mains alternate in their point of connection to the header and the use of the run-around pipe which may be placed under or above the supply mains or discharge mains. For the number of valves and fittings required this arrangement provides at least as much reliability and flexibility as any arrangement the writer has so far encountered. As compared with the Memphis layout shown in Fig. 9, it provides for the same number of pumps and one additional supply main and requires only ten valves and nine tees instead of 18 valves and 12 tees. By adding eight more valves, that is placing two valves instead of one between each pump connection and the adjoining supply connection, the most serious break would shut down only one pump or one supply main instead of both the pump and supply main, giving substantially the same result as at Memphis.

The arrangements shown in Fig. 9 and 10 make unnecessary the providing of valves in the individual discharge pipes from the various pumps, because any pump can be isolated by closing the header valves lying on either side of the tee for the pump connection.

Fig. 11 differs from Fig. 10 in that the pump discharges and supply mains are in line, doing away with the offset at the header. Without the offset higher velocities and smaller valves and pipes might be used with distinct advantage. The valves in the individual pump discharge pipes are more necessary in this case than in Fig. 10 because without them a supply main would be shut down whenever a pump was opened for repair or inspection. This arrangement is at its best when the number of pumps and number of supply mains can be made equal, as they often can be by a little planning.

Fig. 12 shows another application of the idea already illustrated in Fig. 6, that is, of splitting each pump discharge into two pipes each leading to a different supply main. Fig. 12 is equivalent, as regards the number of valves and the results produced by the repair of a valve, to Fig. 10 or to Fig. 11 if the valves in the pump leads of the latter be omitted. It might be more convenient or economical than either of these in some cases.

Fig. 13 shows the header arrangement actually installed in a large city having the same number of pumps and supply mains as illustrated in Figs. 10 and 12. The interesting points about this layout are the unskillful use which has been made of the number of valves and fittings installed and the failure to provide adequately for maintaining service. Thus repair to valve "A" would shut down three pumps which comprise 75 per cent of the station capacity. Repair to valve "B" would shut down three of the four supply mains. Other combinations would shut down one pump and two supply mains or vice versa. It is interesting to note that by using one of the arrangements shown in Figs. 9 to 12 much better results

Figs. 1 to 14—Diagrams Showing Actual or Typical Header Layouts

would have been secured with five less valves and fewer fittings. Or stated in another way, by using three more valves than were actually used and by changing the arrangement it would have been possible to have kept everything in service except one pump or one supply main in the event of the most serious break of a valve.

Most designs could be improved by using more and smaller pumps and mains, particularly the latter. It is often noted that two large mains lead from a station and soon subdivide into say four smaller ones, when at slight cost all four mains could have been led directly from the header, with much greater reliability and flexibility.

Header Details.—In a few places in an effort to secure the utmost reliability, the pipe and fittings in the header systems have been made of rolled steel and the valves of cast steel. The writer believes that as a rule this expensive practice is unnecessary, and is of the opinion that in a suitably arranged header cast-iron fittings and valves are satisfactory. Both fittings and valves however, should be especially rugged and designed for a pressure considerably in excess of the working pressure on the header system.

Where the fittings are larger than 16 in. in diameter it is a good plan to have each of them tapped and plugged at a number of points to make sure that the casting is not unduly eccentric or thin on one side. This precaution is worth while in view of the fact that special castings are not ordinarily put under a pressure test or measured for wall thickness in the foundry. To avoid danger of joints pulling apart it is best to make all of the pipe and valves in the header system flanged. In layouts such as that shown in Figs. 10 and 11 the run-around pipe, since it contains no branches, can be made of steel.

In order to make all parts of the header readily accessible the header should be enclosed in a masonry chamber, with convenient access provided from the pumping station and from the surface. Fig. 14 shows a section of the header used at Memphis, the plan layout of which is shown in Fig. 9. The header system is 24 in. in diameter throughout. The valves are operated hydraulically from a control table located inside of the pumping station near the front wall. The operating water for the valve cylinders is supplied ordinarily by water from the discharge mains, but the boiler feed pumps are also connected to the operating table through a reducing valve for emergency use. When a lever is moved to operate a valve the waste water flows from a pipe at the back of the table and into a funnel connected to the sewer, giving the operator a visible indication when the valve is moving and when it has stopped moving. Except when the table is in use the water supply and water waste connections to the table are kept cut off by valves controlled from the top of the table, for the purpose of preventing unauthorized persons from tampering with the valves. A black line diagram similar to those shown here is framed and mounted at the back of the table and on it every valve is numbered so that the operator can secure a clear idea of what operations are required for any contingency.

Referring to Fig. 14, it will be noted that there is plenty of space below the header piping and valve cylinders to move any of the valves or fittings across the floor to a point underneath one of the hatchways in the roof. Without this space the removal or insertion of a fitting would be quite difficult. Valve cylinders are all placed horizontally so that there is no tendency for the valves to creep when the pressure is cut off from the cylinder. The bypass valves are all placed on top of the main valves and with the operating stems projecting inward toward the center of the loop so that they all can be reached without climbing over the header piping. A large drain leads from one corner of the header chamber to the sewer so as quickly to carry off water that might come from a break in the header system or the pumping station basement.

The Memphis layout illustrates how the various requirements for ready and convenient operation and for access to the header were met in this one case. Whether hydraulic or electric valves should be used in a given case as against hand operated valves, depends considerably upon the number and size of the valves, but there is no doubt that even in small sizes power operation is advantageous and will speed up the valve operations necessary in emergencies. Hydraulic valves are cheaper than electrically operated valves and if connected to the boiler feed pumps or some similar emergency source of water supply, are probably more dependable as to source of power supply in most stations.

It is often advantageous to use high water velocities and relatively small pipe and valves in the header system. This not only keeps down the cost but promotes quickness of operation, ruggedness and reliability as compared with larger piping. In any of the loop arrangements such as shown in Fig. 10, water ordinarily flows both ways around the header, and normally velocities are moderate. When the loop is interrupted by closing valves, velocities will be high, but considering the short time such conditions exist and the advantages to be gained by the smaller sizes a few feet of extra head loss is not a powerful factor.

Except as the need for reliability may be modified by the pressure of low service storage, low service discharge headers should be laid out with the same care as high service headers.

Suction Connections.—On account of the low pressure on the suction side of the pumps and of the greatly lesser likelihood of breaks occurring there, it is unnecessary to have suction arrangements anything like as thoroughly valved and as complex as the discharge header. There are certain criteria, however, which should be met. The suction connection from each pump should lead directly to the suction well or to a concrete conduit, which may be regarded as the equivalent of a suction well, independently of the other pumps. The suction pipe for each pump should project several feet below the lowest water level in the suction well or suction conduit so that the pump may be primed or started or stopped without interfering with the suction to the other pumps. If these requirements be met about the only other requirement to be considered is that it should be made possible to gain access to one part of the suction well or suction conduit and to the individual pipes connected thereto without interrupting service of the remaining pumps. At Memphis there are two separate suction conduits, one arranged to supply three pumps and the other two pumps. Each conduit is controlled by a sluice gate and each sluice gate by double stop-plank grooves, so arranged that either sluice gate or either suction conduit can be isolated without shutting down more than half of the pumps normally available.

Under other circumstances the same effect could be produced with a single suction conduit merely by placing stop-plank grooves at intervals along the length of the conduit and by feeding the conduit from both ends. This is done in the Dallas design where the grooves divide the conduit into three parts, and where the grooves are covered with plates set flush with the basement floor and designed to take the uplift of a full clear water basin. In this case the basin will be lowered when the conduit is to be entered.

The above described suction arrangements are probably sufficient for the average case. For one thing they eliminate the most common fault in suction piping which is to connect the pumps to a single vacuum suction header invariably resulting in troubles in priming the pumps or in keeping them primed during operation.

Foot valves in suction connections are to be avoided, first, because they introduce in an inaccessible location a device likely to require attention and repair, and second, because they are likely to subject the pumps and suction piping, especially centrifugal pumps, to severe shocks caused by water hammer when the checks close.

Check Valves.—Check valves on the discharge side of centrifugal pumps are practically essential in all ordinary cases. In one case where they were omitted a sudden tripping of the pump, and the resulting back flow of water at

high velocity, burst the pump casing. Another danger when check valves are omitted is that the back flow of water will over-speed the pump and cause damage through centrifugal stress before it can be shut off.

For these reasons check valves in the discharge lines of centrifugal pumps seem to be a necessary evil, although the way in which some of them slam shut and cause water hammer when the power it cut off, is a matter of concern to many operators, particularly where the valves are 24 in. or more in diameter. Relief valves should be provided where the danger of hammer is great. After experiencing this difficulty in a number of installations, the writer took up with a valve manufacturer the question of designing a valve which would close with less shock. A multiport valve was required and it was decided to depart from the standard design of that manufacturer to the extent of increasing the number and cutting down the diameter of the ports and making the flaps of a tough bronze instead of bronze faced cast iron. The reduced weight of the flaps and the reduced distance through which they traveled in closing apparently produced a good result as these particular valves close without noise even when the pump is suddenly tripped. Of course, the Larner-Johnson, Automatic Cone or other special combination stop and check valve can also be used to prevent hammer and can be used in sizes much too big for a good gate or check valve. The writer has seen fit to mention this detail because the shocks in many such lines are a serious potential source of unreliability.

The foregoing discussion of headers and pump piping is offered on the basis that it may point out proper methods of approaching the subject rather than with the idea that it will afford a suitable layout fitted to each particular case. Local conditions must be considered in all cases. In every case, however, authorities responsible for planning the piping arrangements should submit their proposed arrangements to the insurance inspection department having local jurisdiction. In all cities above 25,000 population, the National Board of Fire Underwriters, through its Engineering Department, makes a detailed study of the entire water system and it is highly desirable that their criticisms should be secured before the work is built. They are in possession of an abundance of information and know the good and bad features of all important water systems in the country as viewed particularly from the standpoint of reliability of service.

Acknowledgment.—The foregoing is an abstract of a paper presented June 25 at 49th annual convention of the American Water Works Association.

Wages and Hours of Labor of Common Street Laborers in 1928

The entrance wage rates and regular hours of labor of unskilled street laborers directly hired by more than 2,600 cities and towns in the United States have been compiled by the Bureau of Labor Statistics. The full compilation, giving details by individual communities, will appear in bulletin form. A brief summary of this report is given in the June Monthly Labor Review, a publication of the U. S. Department of Labor.

The rates shown are those paid by the municipalities to common laborers when first engaged on the construction, repairing, or cleaning of streets. Higher rates may be paid for greater skill or after a period of service.

The questionnaires for this inquiry were sent out by the United States Bureau of Labor Statistics, under date of October 31, 1928, to all cities and towns having a population of 2,500 or over according to the 1920 census. About 93 per cent of these municipalities replied.

Classified Hourly Wage Rates.—In Table I are given classified entrance wage rates for common street labor, the number of municipalities in each state paying each classified wage rate, as well as the percentage of all municipalities paying each classified wage rate being shown. Of the 2,626 municipalities reporting, 593, or 23 per cent, were paying 40 and under 45 ct. per hour and 553, or 21 per cent, were paying 50 and under 55 ct. per hour. While 896 or about 34 per cent, paid under 40 ct. per hour, only about 15 per cent paid 55 ct. or more.

Classified Weekly Hours of Labor.—In Table II, classified working hours per week of unskilled street laborers are presented. The number of municipalities in each state whose laborers work each classified number of hours per week are shown, and the percentage of all municipalities whose street laborers work each specified number of hours per week are also set forth. Of the total cities and towns reporting, 1,053, or 40 per cent, had a 48 hour

week and 13 per cent a working week of less than 48 hours. On the other hand, 46 per cent had a working week of over 48 hours. While the street laborers in 9 per cent of the cities worked 44 hours or less a week, in 13 per cent of the cities such laborers had a 60-hour week.

Rotating Overhead Spray Cures Precast Concrete Sewer Sections

A new sewer under construction in Waterbury, Conn., is of considerable interest because of its location in the bed of the Naugatuck River. The sewer is of precast concrete construction, the units being 54 in. in diameter and 4 ft. long.

Because of the location of the sewer under water, particular care was taken to secure an impervious concrete of high strength. Proper curing was deemed especially important. The accompanying photograph shows the casting yard, illustrating the method of curing the finished sections. Simple A-frames were set up with roller bearings at the tops. A line of perforated pipe was laid upon these roller bearings and connected at the end with a small water motor of the type used to rotate large lawn sprinklers. When water was turned through the piping, it fell in sprays, keeping the curing sections in a cloud of moisture. The sprinkling was carried on continuously—day and night. During the daytime the spray was supplemented by a boy with a hose, who patrolled the units and sprinkled portions of the concrete pipe not reached by the spray. The photograph was taken shortly after the manufacture of the pipe was begun and shows only one line of sprinkler pipe. Later two and three lines of pipe were used so that the precast pipe could be kept thoroughly wet for 10 days in accordance with the requirements of the specifications.

As shown in the illustration, the mixer was placed on a platform at the end of rows of forms. Concrete was transported on a raised runway. Concrete was usually placed in the forms between 10 and 2 o'clock, and it had usually set sufficiently to allow removal of the forms by the next morning. The forms were then stripped and the pipe was moved into line below the sprinkler for curing.

The pipe used in this project is being manufactured by the Newark Concrete Pipe Co., of Newark, N. J. The sewer is being built under the direction of Robert A. Cairns, City Engineer of Waterbury, with Truman M. Curry, Jr., Assistant Engineer, in charge of design, location and construction work.

Sprinkler System Used for Curing Precast Concrete Sections for Naugatuck River Sewer in Waterbury, Conn. The Overhead Rotating Spray System Was Found Very Effective in Securing Proper Curing

Air-Port Design Competition

The Lehigh Portland Cement Company is sponsor of a competition for the design of a modern air-port, details of which may be obtained by writing the company at Allentown, Pa. The competition will close Nov. 18, 1929. Engineers, architects and city planners may compete. Entries consist of two sheets, each containing two principal drawings. Fourteen cash prizes aggregating $10,000 will be awarded, as follows:

First prize	$5,000
Second prize	2,500
Third prize	1,000
Fourth prize	500
Ten honorable mentions, each	100

Acquiring the Research Habit

By HALBERT P. GILLETTE

KNOWLEDGE consists in knowing facts; wisdom, in knowing their relationships. Perhaps this is a rather arbitrary distinction between these two words, but it serves at least to emphasize the difference between mere fact gathering and the discovering of the significance of facts.

"Those who refuse to go beyond a fact rarely get as far as fact," said Huxley, and he added, "anyone who has studied the history of science knows that almost every great step therein has been made by the anticipation of nature, that is, by the invention of hypotheses which, though verifiable, often had very little foundation to start with."

In a letter written in 1861 Charles Darwin said: "About 30 years ago there was much talk that geologists ought only to observe and not theorize; and I well remember someone saying that at this rate a man might as well go into a gravel pit and count the pebbles and describe the colors. How odd it is that anyone should not see that all observation must be for or against some view if it is to be of any service." At another time he said "I am a firm believer that without speculation there is no good and original observation."

Coming from a man who was one of the most painstaking of observers and experimenters, and the author of a theory that is without equal in its effect upon biological science, such an attitude toward the framing of scientific hypotheses is not to be brushed aside. Darwin's biographers all say that he was exceptionally prolific in devising hypotheses to explain phenomena. One of them quotes him as saying: "Hence it has become a passion with me to try to connect all such facts by some sort of hypothesis." And again: "I have steadily endeavored to keep my mind free so as to give up any hypothesis, however much beloved (and I cannot resist forming one on every subject), as soon as the facts are shown to oppose it." However, he did not live up literally to this last statement, for several times when his theory of evolution seemed to be seriously controverted by certain facts, he clung to it. Many a competent naturalist, such as Agassiz, cited many a fact that seemed to be unanswerable by Darwin's theory, yet Darwin adhered to his belief in its fundamental soundness. Apparently he reasoned that a new theory should be judged mainly by what it explains rather than by what it fails to explain.

The doctrine that was prevalent a century ago among geologists and astronomers, to which Darwin made reference in the letter above quoted, still controls not a few scientists. Recently an experienced astronomer wrote the editor that the time is not yet ripe for theorizing about the origin of our solar system. If Darwin is right, the time was ripe for such theorizing when Galileo made his telescope. Commenting directly upon such matters. Darwin said: "How many astronomers have labored their whole lives on observations, and have not drawn a single conclusion."

In a letter written in 1871 he says: "I have been speculating last night what makes a man a discoverer of undiscovered things, and a most perplexing problem it is. Many men who are very clever—much cleverer than the discoverers—never originate anything. As far as I can conjecture, the art consists in habitually searching for the causes and meaning of everything which occurs."

There is a world of truth in this last statement, but the word "habitually" should have been printed in capitals. How to become an habitual seeker of causes and meanings is a great problem. Darwin not only denies that his training in two universities failed to make him such a seeker, but he asserts that his university time was mostly wasted: "During the three years which I spent at Cambridge my time was wasted, as far as the academical studies were concerned, as completely as at Edinburgh and at school." He was born in 1809, and when he was at Cambridge physical science was little taught. Yet it is rather surprising to hear so modest a man say: "I consider that all I have learnt of any value has been self-taught." Surely he did not have in mind what he learned from books, but regarded that as part of his self-taught knowledge. The opening chapter of his "Origin of Species" contains many references to books and articles by men who had had more than mere glimpses into the secrets of evolution, and his biographers tell of his painstaking indexing and abstracting of books and articles throughout his long and industrious life. We are, all of us, prone to regard what we learn in that manner as being "self-taught." Henry Ford, in his book, makes the same error, for he speaks of his careful reading of all that could assist him in designing automobiles, and then adds that he learned most from his own experiments. That he learned most from published matter is beyond question when consideration is given to what he himself added to the art of automobile designing.

When we see what Darwin accomplished without much aid from his university training, and what Ford accomplished with no such aid, and remember that many another originator and inventor has succeeded greatly in spite of little scientific schooling, it should be evident that most of science can be learned from books and articles, without the assistance of teachers. Moreover, it is almost self-evident that any studious man of middle age has necessarily learned vastly more from the printed page after his formal schooling ended than he learned at school.

Darwin's rebellious attitude toward Cambridge may have come from his perception that Cambridge did nothing to make him an habitual inquirer as to the causes of things. If so, then most of our American graduates of colleges and universities could justify a similar rebellion. We have yet a long road to travel in America before it is generally realized that the primary function of schooling is to make the students habitual inquirers. Only in a few American institutions of higher learning is training conducted continuously so as to effect that result. Studying the fundamental principles of science does not accomplish that result. Mathematical training does not. Then what does? Nothing but repeated practice in systematic searching for the answers to questions, and particularly to questions that can be answered only by the collecting and weighing of many facts.

If it be objected that we can not all be Darwins or Fords, and that such men will always find ways of training themselves, then the objector has completely failed to understand the primary object of mental training. It is not to acquire knowledge, or even to acquire wisdom, that we take courses of study in college, for neither is acquirable to any considerable extent during the schooling period. It is to become habituated to secure and analyze facts with a view to answering some definite question.

The question may be, What is the most economic pavement to lay for the service that it will probably be required to render? Simple though it sounds, this is a very difficult problem in many cases. The question may be, What business or profession should I enter and where? More than 99 per cent of men guess at the answer, for they have never been habituated to solve problems by the fact-gathering method. The question may be, Why is my business unprofitable although my competitor is thriving? No solution is there for such a problem other than fact-gathering and analysis. Nearly all the problems in life are of these sorts, and then solution is correctly made only by those who are either instinctively fact-hounds, or have become habituated to searching for usable facts and their significance.

Mechanical Developments in Water Treatment Practice

Use of Mechanical Clarifiers and Agitators in Water Treatment

By C. T. LEANDER
Branch Manager, The Dorr Co.

IN this paper the discussion will be confined to the unit operations of presedimentation, sedimentation, chemical softening and chemical coagulation, their relationship one to another, and their relationship to the other unit operations in several typical flowsheets which have been found effective in the case of three frequently encountered treatment problems.

The mechanical equipment for carrying out these unit operations which we are qualified to discuss, are the Dorr traction clarifier and the Dorr impeller agitator.

The Clarifier.—The Dorr Traction Clarifier, as shown in the accompanying illustration, is a continuously cleaned sedimentation basin which, when receiving as its feed raw or chemically dosed water introduced through submerged ports along the influent side, overflows continuously a clarified water across a weir at the effluent side opposite and discharges a thick sludge from a bottom connection. It operates continuously, is never shut down for manual cleaning and duplicate or stand-by units are not needed. The total tank contents are at all times available for detention purposes as sludge is removed at the rate of deposition. The old device which it displaces is the well known settling basin, rectangular in shape and constructed of concrete and masonry.

The Agitator.—The Dorr impeller agitator was developed to satisfy the conditions prevailing in water treatment, that is, effective turnover of the raw water to give homogeneity throughout but at a velocity at which flocs will form and build up rapidly. The illustration of a cross section through such an agitator is almost self explanatory. A slowly revolving marine impeller in a cylindrical draft tube induces a gentle circulating motion of the tank contents, upward through the tube and downward in the annular space surrounding it. A velocity between .5 ft./sec. and 1.5 ft./sec. is maintained as at this velocity flocs build up readily, yet do not settle on the tank bottom. In order to insure complete treatment of all the water with a minimum of short circuiting, two or three agitator tanks, arranged in series, are recommended. Vertical baffles, at right angles to the flow line between influent and effluent ports, and extending from the bottom to slightly above the water level, minimize swirling and cause all of the water to pass through the draft tube at least once.

These Types of Treatment.—With this brief outline of the salient features of the clarifier and agitator, consideration may be given to the development of flowsheets for handling the following three common problems:

	Character of Raw Water	Treatment	Chief Unit Operations
1.	Turbid and soft	Clarification	Coagulation Mechanical sedimentation (Plain sedimentation) Filtration
2.	Clear and hard	Softening	Softening Mechanical sedimentation Plain sedimentation Filtration
3.	Turbid and hard	Clarification Softening	Mechanical presedimentation Coagulation and softening Mechanical sedimentation Plain sedimentation Filtration

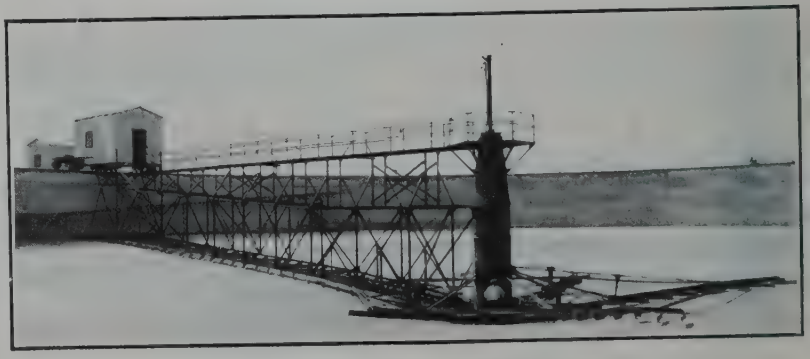
These three types of treatment are well known. It is conservatively estimated that they cover 80 per cent of the problems encountered in water works practice. Simple as they are, they have been the subject of much study by the leaders in the development of modern practice, as Hoover, McDonnell, Graf, Flemming, to mention only a few, have been instrumental in moulding practice in each case to a point where chemical and mechanical controls approach very closely to perfection. As this paper cannot attempt to deal with all phases of improved technique, it will attempt simply to show the relationship of mechanical clarifiers to each of these three common problems, quoting operating figures at typical installations insofar as possible.

Turbid, Soft Water.—Water containing excessive amounts of suspended solids, yet in other respects, such as hardness, suitable to domestic and industrial use is found chiefly along the seaboard as distinguished from the great hard water section in the mid-western and central portion of the country. The accompanying diagram shows diagrammatically in simplified form, the unit operations.

The turbid water is treated with suitable coagulants, such as alum or iron sulfate, and properly conditioned or coagulated in a series of agitation tanks in which mixing is maintained at a velocity suited to rapid flocculation. In the mechanical sedimentation tank the floc settles rapidly, yielding a clarified effluent from which the slight remaining turbidity may be readily removed on rapid sand filters. Chlorination after filtration may or may not be employed, depending upon local conditions.

The plant of the city of Lancaster, Pa., is typical of this type of treatment. The tabulation which follows gives the salient features of the chemical treatment and the operating results of the mechanical clarifier.

Clear, Hard Water.—Clear water, excessively hard, is a common occurrence in the great hard water section of the



The Dorr Traction Clarifier at Kansas City, Mo.

Table I—Treatment of Turbid Water at Lancaster, Pa.

Year Installed	1926

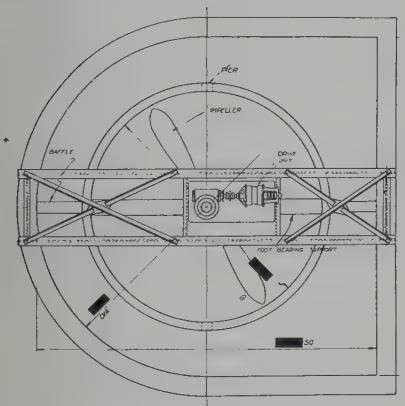
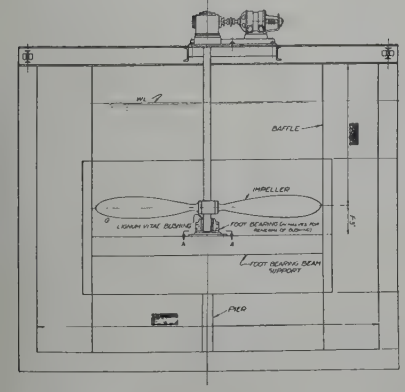
Detention provided	1 hr.
Feed concentration P.P.M.	Max. 2,000
Feed concentration P.P.M.	Aver. 80
Overflow concentration P.P.M.	15—18
Clarification efficiency	80—90%

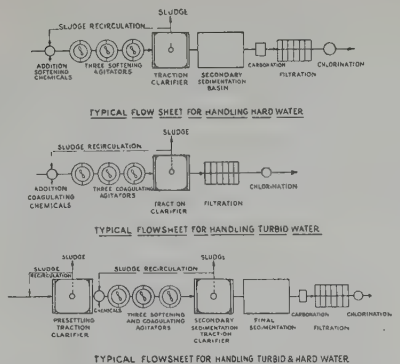
middlewest and the southwest. This condition is particularly prevalent in the states of Ohio, Illinois and Michigan, where many modern softening plants are found. The diagram illustrates a type of treatment which is used successfully for handling water of this character.

The hard water is dosed with the correct amount of softening chemicals, and the softening reaction and formation of flocs completed in the agitator tanks which follow. In the mechanical sedimentation basins the bulk of the floc is removed so that the duty on the plain sedimentation tank is greatly reduced, thus minimizing sludge accumulation and the need for frequent cleaning. The settled water is finally treated on rapid sand filters, preceded by carbonation and followed by chlorination if local conditions make these additional steps desirable.





Dorr Impeller Agitator



Flow Sheets for Handling Various Types of Water Using Agitators and Clarifiers

In the recently designed water softening plants for the cities of Fostoria, O., Bloomington, Ill., and Boca Raton, Fla., plain sedimentation tanks have been eliminated. Single stage sedimentation in mechanical clarifiers yields an effluent containing such a small amount of suspended solids that final treatment on rapid sand filters is all that is required. Such plants as these are 100 per cent mechanically operated as far as sludge handling is concerned.

Table II gives operating data at five representative waterworks handling hard water. The treatment in general follows the lines laid down in the diagram. The raw water is clear in most cases, as it comes from deep wells. The Dorr clarifiers, which in each case remove the bulk of the floc ahead of plain settling basins, effect a 75 to 98 per cent removal of the precipitated solids, thus greatly reducing the duty on the subsequent equipment.

Turbid Hard Water.—That portion of the country which is drained by the Mississippi, Missouri, Arkansas and Red Rivers is noted for the high turbidity and moderate hardness of its water supply. These hard river waters contain turbidities ranging from 3,000 to 10,000 parts per million. Ofter for as long as a week the turbidity stays at 18,000 p.p.m. or higher, while for short periods turbidities of 40,000 p.p.m. have been observed. The difficulty of keeping non-mechanical sedimentation equipment in service under such conditions, may be visualized by considering the following. A turbidity of 10,000 p.p.m. is equivalent to 5,830 cu. ft. of 80 per cent moisture sludge per million gallons of water treated. With such an average turbidity, a sedimentation basin having a detention of 24 hours will be full of mud in 23 days, with 12 hours' detention in 11.5 days and with 6 hours' detention in 5.7 days.

The manual cleaning of settling basins in this section used to be a frequent and major operation, often requiring several weeks' work and the use of a large number of tractors, motor vehicles and teams in addition to a large force of men. Nowhere, it is safe to say, has the mechanically cleaned sedimentation basin helped so greatly in water works practice. An approved layout for handling turbid hard water provides for mechanical presedimentation ahead of chemical treatment and secondary mechanical sedimentation following chemical treatment as shown on the diagram.

The highly turbid raw water enters the mechanically cleaned presedimentation basins depositing therein about 90 per cent of suspended solids which are continuously discharged into the river. The presettled water is thereupon mixed with suitable softening chemicals, agitated at a velocity conducive to rapid flocculation and then resettled in the mechanically cleaned secondary sedimentation basin. The overflow from these, containing only a small amount of suspended material, is given a long detention in simple sedimentation tanks and filtered with or without prior carbonation and subsequent chlorination as the situation may require.

With such an arrangement the difficulties attending the handling of highly turbid waters largely disappear. Practically all of the mud and precipitate is removed and disposed of mechanically, thereby reducing the deposition in the final non-mechanical basins and filters to insignificant volume. Presettling furthermore, by reason of the low tur-

bidity effluent, results in smoother plant operation, simpler chemical control, practically halves the cost of chemicals for coagulation and softening and reduces the cost of the water wasted with the sludge, as this water has not been given the expensive chemical treatment. Furthermore, the return of a portion of raw sludge to the influent channel of the presedimentation clarifier improves the rate of settlement, presumably through entrainment of fines. A similar recirculation of chemically treated sludge in the case of the secondary clarifier has been shown to accelerate the rate of softening, probably due to a reduction in supersaturation or a catalytic speeding up of the reaction.

The use of the mechanical clarifier for presettling turbid water is a comparatively recent development. Four cities—Kansas City, St. Louis, Jefferson City, Mo., and Edmonton, Alberta—with a combined flow of 200 M.G.D. have adopted Dorr clarifiers for presettling, while St. Louis uses the clarifier for settling the chemically softened water as well. In none of these cases is operating data available at the present time.

Studies made at Jefferson City, Mo., in 1925 brought out on a semi-works scale the most important data bearing on presedimentation practice. Operating results (Table III) at Jefferson City during an 11-day run show the character of the results which should soon be obtained at the large installation referred to previously.

Presedimentation of turbid waters before chemical treatments results in a great saving in chemicals as the chemical dosage increases with the concentration of solids. Runs made at Jefferson City, treating the raw river water without presettling, showed that the coagulants required for clarification could be reduced to approximately one-half their former amount if the raw water were first presettled for three hours. Fleming, in a paper on Preliminary Sedimentation and Basin Detention at St. Louis, read in January, 1927, before the American Water Works Association, showed that his studies indicated an annual saving of $53,313 in iron sulfate and lime through subjecting 80 m.g.d. of Missouri River water to 3 hours presettling before the addition of chemicals.

The three flowsheets discussed in this paper are not to be construed as panaceas for all problems, for each problem is different from all others in a greater or lesser degree and must be approached from the professional angle as a separate and distinct one. Nevertheless the flow sheets presented do indicate the general features of plants having to contend with three frequently encountered water conditions and they do bring out the approved position of the mechanical clarifier with respect to other units in the layout.

The elimination of the difficulties inherent in the operation of intermittently cleaned settling tanks has undoubtedly been a forward step at many waterworks recently built or remodeled. The inevitable change in practice has had the cumulative effect of reducing the cost of producing a unit of potable water through continuous operation under uniform conditions which are conducive to simpler mechanical and chemical controls.

Acknowledgment.—The foregoing is an abstract of a paper presented at the 49th annual convention of the American Water Works Association.

Table III—Presedimentation Tests at Jefferson City, Mo., July 15-18, 1926

Source of water supply	Missouri River
Average suspended solids in raw water	5,844 P.P.M.
Type and size presedimentation unit	Dorr clarifier 25 ft. dia. by 8 ft. deep
Detention provided in presedimentation unit	3 hours
Average suspended solids in overflow from presedimentation unit	417 P.P.M.
Average removal of suspended solids	92.8 per cent
Type and quantity of chemicals added to presettled water:	
Iron sulfate (average dose)	3.2 grains per gal.
Lime (average dose)	3.6 grains per gal.
Secondary sedimentation unit	15 ft. by 15 ft. plain basin
Average suspended solids in overflow from secondary sedimentation unit	36 P.P.M.
Average removal of suspended solids	91.5 per cent

Per Capita Water Consumption in Metropolitan District

The following tabulation for the annual report of Frank E. Merrill, Water Commissioner of the City of Somerville, Mass., shows the per capita water consumption in the Metropolitan Water District of Massachusetts for the year 1928.

	Total Per Day	Per Capita Per Day	Services Metered*
Milton	740,000	52	100
Medford	2,902,700	56	100

*Metropolitan District Commission Report for 1927.

Hot Water Melts Ice in Pueblo Streets

Hot water was used with considerable success this last winter by the city of Pueblo, Colo., for removing snow and ice from the streets, according to E. E. Colby, superintendent of parks and highways.

The Highway Department of Pueblo is troubled considerably with light snows which result, through the compacting of traffic, in the formation of a layer of ice upon the pavements and in the gutters. This is not only unsightly, but it also creates traffic hazards and impedes drainage. As removal with picks and bars has proved expensive and, at the best, unsatisfactory, it was decided to use the hot water from the condensers of the local ice plant to remove the ice from the streets.

The regular combination sprinkling and flushing unit—a 5-ton White truck equipped with 1,100-gal. tank and auxiliary pump motor—was used. The tanks were loaded at the plant in approximately 20 minutes and arrived at the job with the water at about 175 deg. The water was released slowly under low pressure and, with the assistance of a man with a bar, rapidly thawed the ice, which was carried into the sewers.

This was found to be a highly satisfactory method for disposing of the ice if the weather is not extremely cold. At very low temperatures, the water freezes, forming a light glaze of slippery ice which is as much of a danger to traffic as the heavy coating of ice disposed of through the sewers.

Progress of City Manager Plan

The Kentucky Court of Appeals, according to the Toledo City Journal, has held the city manager act in that state unconstitutional, because it was held to (1) violate a state constitutional provision that the mayor shall be the chief executive; (2) allow an authoritative position to be appointive rather than elective; (3) be faulty in its title. Three Kentucky cities, Lexington, Covington and Owensboro, had already voted to adopt the plan at the last November election.

Redwood City, Calif., recently adopted the city manager plan. The charter contains the rather striking provision that the manager must have previous training as a city manager, assistant, or deputy manager. A similar provision is contained in the proposed plan for New Rochelle, N. Y. The charter commission in St. Paul is considering the plan and officials and civic leaders in Omaha, Nebr., are considering its adoption. The plan was recently rejected in Lincoln, Nebr.; Sedalia, Mo.; Evansville, Ind., and Terre Haute, Ind.

Man's Descent from a "Protoplasmic Globule"

In one of Gilbert and Sullivan's operettas a character says: "I can trace my ancestors to a protoplasmic globule." Said in jest, there may be truth in the statement. At any rate it is probable that evolution is a fact, and once we start to backtrack on that trail no end seems possible, save the "protoplasmic globule," and even that is not the end.

According to authorities on geology every geological era ended, and its succeeding era began, with an ice age. Every ice age had a profound effect on animal life, certain species vanishing and new species appearing. Huntington has suggested that man completed his evolution from the simian stage during the last ice age.

If we accept this hypothesis that animal evolution was greatly hastened by ice ages and other great climatic changes, and couple it with the hypothesis that climatic changes have been caused by great variation in sunspot activity, we reach this formula: No sunspots, no man; or at least no man in his present form.

Let us go a step farther in the analysis. Sunspots are great electromagnetic whirls, and the evidence is strong that they are generated by other electromagnetic fields, namely, those produced by the axial rotation of the electrified masses of planets and comets. Lying beyond the farthest known planet, Neptune, are comets, some of which have orbital periods that run into millions of years. Since all the superior planets have comets whose aphelia lie in the orbits of the planets, it is presumable that the converse is true and that at least some of the most remote comets are similarly associated with planets as yet unseen. Since it has been demonstrated that every one of the known eight planets produces a sunspot cycle, it follows that any trans-Neptunian planet probably produces sunspots, their number and size depending upon the strength of its electromagnetic field, the direction of its magnetic axis relative to the sun and the position of its magnetic poles. When the north pole of the sun points most nearly toward the earth, more pronounced barometric laws occur, indicating that anti-clockwise rotation of solar electrons probably causes release of more terrestrial electrons and certainly causes rising air whirls. Sunspots rotate and produce similar barometric effects. So we reach the conclusion that since sunspots produce cyclonic movements of terrestrial air, certain trans-Neptunian planets caused those great storm periods that we call geological ice ages.

This brings us abruptly to another formula: No electromagnetic whirls; no man.

Since the ultimate unit of electricity that accounts for magnetic effects is the electron, we conclude: No electron, no man; and by the same token, no electron, no "protoplasmic globule."

The World's Need of Researchers

Scientific research began scarcely more than three centuries ago, with Galileo, Kepler and Gilbert. Marvelous as its achievements have been, perhaps a greater marvel is that they are the accomplishment of relatively few men. It has been the custom to explain this fact by saying that genius is a rare gift. Yet, if the phenomenon is purely one of difference in mental power, and in the rarity of that supreme power called genius, how comes it that there were almost no scientific geniuses prior to about the year 1600? Scientific genius did not suddenly evolve at that time in a few humans. We must therefore infer that men had not till then learned how systematically to interrogate Nature so as to secure definite answers to their questions.

Although this explains, in a general way, the birth of modern research, still it leaves unexplained the fewness of researchers. Even yet their number is pitifully few when contrasted either with the total population or with the economic needs of that population. Doubtless much of the reason for so little researching springs from general ignorance of the nature of research. This ignorance has served to cast a screen of mystery about the art, leading to the belief that only a few divinely gifted mortals can successfully penetrate the winding labyrinths that lead to Nature's holy of holies.

Germany has done more than any other nation to dispel this particular delusion. By training thousands of young men in research methods, German universities have proved that research ability is by no means rare. But, even in the face of such proof, America has been exceedingly slow in entering upon a career of scientific research. Most of us still regard successful research as a thing unteachable, and confined to a gifted few who will somehow or other develop their native talents even in the face of public indifference and in the absence of pecuniary support.

This last clause gives the clue to much of the apathy toward research by men capable of research. The spirit of martyrs is usually found only where public applause accompanies self sacrifice. Many a man will bravely hurl himself into any breach if he knows that his bravery will be appreciated by his fellow men. But when self-sacrifice brings not even a murmur of approval, it becomes a rare thing. The self-sacrifice of the scientific researcher is of this latter sort. He would starve in a garret if assured glory were the reward; but almost the only reward for his research work is apt to be his daily wage, for his renown will probably not extend beyond the ranks of the very few of his own scientific class who are capable of appreciating his achievement. The wonder is that these few are not fewer.

Up to very recently scientific research was almost

entirely in the hands of a few college professors. Small as the salaries of such men have been, still the income served to maintain them, and their daily duties were such as to leave some freedom for investigating natural causes and effects. If even such scant support has served to develop a body of researchers whose achievements have already revolutionized industry, imagine what might have happened in the past three centuries had the same support been provided for ten times their number.

We venture to say that not a single one of the major death-dealing diseases would remain unconquered had ten times as many biological researchers been engaged in seeking causes and cures. We are so sure that successful research is teachable, and that native research ability is not rare, that we regard it as certain that multiplying the number of trained researchers by ten would multiply the discoveries by ten. Indeed, we may safely go much farther, for each discovery itself throws light on other research problems. Hence discoveries tend to multiply in a sort of geometric progression. This is one of the reasons for the startlingly rapid advance of science within the last generation. Another reason is the pecuniary support of research laboratories by many industrial corporations. At last "big business" has begun to see that behind the inventor is the research scientist who furnishes him with his basic ideas; and that behind both inventor and scientist there must be dollars if the combined achievements of these two groups are to be rapid and great.

Take the element of time. Where Goodyear labored the better part of a lifetime to learn how to vulcanize rubber, a great modern chemical research laboratory would probably accomplish the result in a year. In the place of one Goodyear there would be a score of chemists. In the place of his kitchen chairs and tables, burned in that last fine frenzy to keep the rubber in the pot boiling while he added sulphur, there would have been exhaustless fuel.

All honor to Goodyear the Gritty, to Goodyear the Great! But where is there any honor for his blind contemporaries? Neither praise nor pay did they give him, but left him to fight his research battle alone. Does this indicate at that time a public ignorance almost barbaric? It does, and scarcely less is the ignorance of the public of today. Scourged by diseases, poverty stricken as to nine-tenths of this globe, the world is still so ignorant of what research science could do to remove these blights on health and happiness that it looks with bovine eyes at its ills and never dreams that cures are to be had. Its suffering is pitiful; its ignorance is appalling.

Tornadoes and Sunspots

The Pasadena Post recently said: "Never before have the papers of this country had to record such a series of disasters due to tornadoes as have marked the present seasons. Day after day additions have had to be made to a somber list already large beyond known precedent."

The tornado is a belt of air whirling with great velocity, and in the northern hemisphere its direction of whirl is always anticlockwise, whereas in the southern hemisphere its whirl is clockwise. As to the direction of whirl it resembles the ordinary cyclone storm that originates in the Pacific Ocean and sweeps across our continent, but the velocity of whirl is much greater in the tornado. The tornado is short lived, an hour or so, whereas the cyclonic storm often lasts a week or more. The centers of both travel eastward.

Closely allied to the tornado is the tropical hurricane. The latter is, in fact, a giant tornado whose wind velocities are not so great as those of the tornado, but whose area is vastly greater. Hurricanes move westward before they turn eastward, their paths often being almost perfect parabolas.

The following table, compiled by Wolf and quoted by Huntington in "Earth and Sun," shows how hurricanes increase in number as sunspots increase.

Number of Sunspots	Number of Hurricanes
88	8
70	5
62	4
59	3
17	1 to 2

This table gives the number of hurricanes per year, with the corresponding monthly average of sunspot numbers.

Huntington also found that during the spring months hurricanes were 69 per cent more numerous when the average number of sunspots exceeded 80 than when they were fewer than 40.

Cyclonic storms are also most numerous when sunspots are most numerous.

Since tornadoes are clearly of the same nature as cyclonic storms and hurricanes, it follows that they should be most numerous at times of sunspot maxima. Since a sunspot maximum due to the planet Juipter was due about the first of November, 1928, it was to be inferred that the spring of 1929 would be marked by many tornadoes. This inference has been verified, an unusually stormy fall and winter in northern latitudes having been followed by an exceptionally large number of tornadoes in somewhat lower latitudes.

The sunspot cycle due to Jupiter reaches a maximum every 11.2 years, unless some more electromagnetically powerful planet submerges the Jupiter effect. Uranus has caused such a submergence at times. The next sunspot maximum assignable to Uranus will occur in 1951, just six months after a Jupiter sunspot maximum; hence it is probable that an exceptionally severe period of storms will reach a climax in 1951.

From now on the Jupiter sunspot period will slowly wane. Its next maximum will occur eleven years hence, in 1940.

According to Encyclopedia Britannica, Lloyd's has found that ship casualties are 18 per cent more numerous during the two years near sunspot maxima than during the two years near sunspot minima. Although this marine insurer has based rates upon such a relationship between sunspots and storminess, still there are meteorologists and astronomers who express skepticim about sunspots as a cause of storms. Perhaps there is a difference in carefulness of investigation when you back your conclusions with your money.

H. P. Gillette

The Chlorine Institute Standard Valve for Compressed Gas, Cylinders and Drums

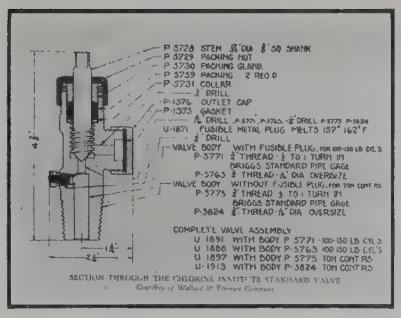
One of the finest examples of co-operation in the cause of public health between manufacturers of water works equipment and health and water works officials is in the development of the new Chlorine Institute Standard Tank Valve for chlorine cylinders and drums.

Although water works officials had for years, on frequent occasions, experienced delays and inconveniences due to receipt of a shipment of chlorine gas cylinders requiring yoke connections for auxiliary valves when fittings on hand were for the union type of attachment and vice versa. It required an emergency situation developed in the course of relief work following the Florida hurricane of 1926 to bring the seriousness of the then existing practice to a head.

The incident in point occurred at Hollywood, Fla., in September, 1926, when a shipment of several cylinders of chlorine gas delivered for emergency chlorination of water supplies could not be used because the cylinders required yoke type fittings while only the union type connections were on hand.

At a special meeting of the Public Health Engineering Section of the American Public Health Association on Oct. 13, 1926, at Buffalo, experiences in emergency chlorination of public water supplies following the Florida hurricane were the subject of a very interesting discussion. Before the close of the meeting the following motion was made by V. M. Ehlers of Texas, duly seconded and carried unanimously: "Moved that the secretary communicate with the Chlorine Institute and also the American Water Works Association with reference to the standardization of tank valves on chlorine cylinders."

Chlorine Institute Standard Valve with W & T Union Type Auxiliary Valve



Section Through Chlorine Institute Standard Valve

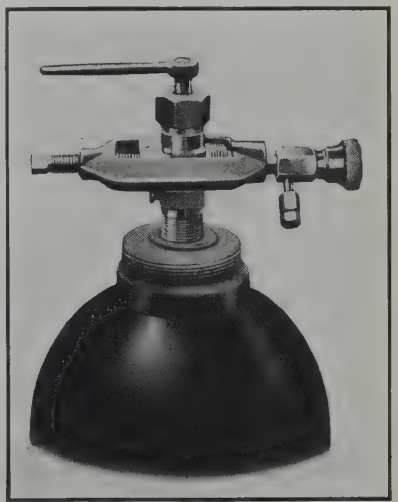
On receipt of communication from Arthur E. Gorman, secretary of the Public Health Engineering Section, referring to this action of the section and requesting its serious consideration by the Chlorine Institute, the directors of this organization at a meeting on Dec. 16, 1926, forwarded the communication to a special technical committee for investigation. This committee after very careful survey of conditions and a study of all types of valves, designed an entirely new valve adaptable for both union and yoke type connections which was accepted is now being manufactured. It is known as the Chlorine Institute Valve.

Investigations of this committee showed that but a relatively small percentage of the chlorine valves owned by manufacturers in the chlorine industry were used in the sanitary field. Also that the investment in these valves was a substantial one making their discards for new valves an expensive matter. However, in view of the health aspects of the situation the manufacturers decided on a policy of purchasing Chlorine Institute tank valves for the replacement of all discarded valves in use. The replacement by new valves was then confined entirely to containers used in the sanitary field.

It was estimated that this procedure would over a period of a few years permit the replacement of all valves used in the sanitary departments of their business with the new Chlorine Institute Tank Valve. It is estimated that to date there are approximately 25,000 of the new type valves in use.

They are being manufactured exclusively by the Wallace & Tiernan Co. and users report very satisfactory results with them. The new valve incorporates the best features of all valves in service. Among the features of the valve are a one piece genuine Monel metal stem, a brass forged body with 3/16 in. seat opening for the cylinder valve, and ¼ in. seat opening for the ton drum valve, an extra long and over size shank thread which allows for wear of the thread in the cylinders and gives increased length of life of the body, brass packing nut, gland and ring, so arranged as to permit packing the valve while in service, the use of soft packing, and the use of a removable bronze fusible metal container plug. The fusible metal represents the result of very extensive research work carried on by the members of the Institute. The outlet connection has the ¾ in. external straight pipe thread, which has been used in the industry for years, to accommodate a union connection and is also equipped with a recessed gasket surface to accommodate the use of an adapter and yoke. The packing nut takes the same wrench as the outlet cap.

The water works and public health professions and the members of the Chlorine Institute are to be congratulated for handling this important situation in such a business like and cooperative way. It is another indication of the fine spirit which exists in American industry in regard to public welfare.



Chlorine Institute Standard Valve with W & T Yoke Type Auxiliary Valve and Yoke

High Curbs on Toronto Bridge Promote Pedestrian Safety

Curbs on the new steel arch bridge carrying North Glen Road over the Park Drive ravine in Toronto, Ont., were made 15 in. high to assist in preventing motor traffic from mounting to the sidewalks. Regular 6x6-in. curbs are provided at the bases of the high curbs to prevent the scraping of automobile hub caps on the walls of the high curbs.

Green Sidewalks for New Orleans

New Orleans, it is stated, is soon to have colored sidewalks. The commission council has approved the paving of the sidewalks of Baronne St., from Howard Ave. to Canal St., with light green cement. This will eliminate to some extent the glare from the strong sunlight.

A New Chlorine Colorimeter

A new piece of equipment, known as the LaMotte chlorine colorimeter, for determining free or residual chlorine in drinking water, has recently been developed by the LaMotte Chemical Products Co., Baltimore, Md. The set

LaMotte Chlorine Colorimeter

consists of 8 permanent chlorine color standards in LaMotte "Sealed Nessler tubes" with polished tops and bottoms, representing 0.02, 0.04, 0.06. 0.08, 0.10, 0.15, 0.20 and 0.30 parts per million of chlorine respectively; three open Nessler tubes for the test sample; a 50 cc. bottle of Ortho Tolidine reagent with 0.5 cc. pipette and nipple; and a LaMotte Colorimeter for Nessler tube comparison. All this equipment is compactly arranged in a polished wooden case with a sturdy handle for carrying.

Previously great difficulty has been experienced with standards kept in open Nessler tubes, due to contamination from cork and rubber stoppers, and both contamination and loss of material if the solutions are kept in bottles and poured into the tubes when determinations are made. To eliminate these difficulties, all standards, including those for color, nitrogen, chlorine, iron, nitrate, etc., are put up in closed Nessler tubes with polished tops and bottoms, as recommended by F. R. Georgia (J. A. W. W. Assoc., May, 1926). The standard tubes are filled thorugh side arms which are then sealed off, preserving the standards from contamination of any kind. The special colorimeter must be used in making determinations with these sealed standards.

In making the determination, one of the open Nessler tubes is filled to the mark (50 cc.) with the water to be tested, 0.5 cc. of the Ortho Tolidine reagent added by means of the pipette, the tube shaken to ensure thorough mixing, and placed in the middle hole of the colorimeter.

Two consecutive color standards, for example, those representing 0.04 and 0.06 ppm. are then placed in the remaining two holes on either side of the test sample. The tops of the tubes are held toward a window or other source of daylight, and the standards changed if necessary, until the color of the reflection of the test sample in the mirror either matches that of the reflection of one of the standards or lies between the two. If an exact match is obtained the chlorine concentration in parts per million is read off directly from the standard with which the match is obtained. If the color lies between those of the standards on either side, the reading is taken as the average of the two. Thus if it lies between 0.04 and 0.06, it is taken as 0.05 ppm.

This set is also supplied with permanent standards and reagents for determining Nitrogen, Nitrates, Nitrites, Total Iron, Manganese, etc.

The new principle of making determinations by matching the reflection in the mirror, instead of by looking down through the tubes makes the readings much more simple and accurate.

Worthington Compressors Timken Equipped

A new line of compressors, employing Timken roller bearings on the main crank shaft journals, is announced by the Worthington Pump and Machinery Corporation, Harrison, N. J. This is the Worthington single horizontal straight line series, so popular among smaller users of compressed air. Capacities range from 100 to 300 cu. ft. per minute and, operating at moderate speeds, maintenance charges and attention are said to be almost completely eliminated.

Oil rings, which deflect the surplus oil and return it to the crank case, are mounted on the shaft beyond the Timken bearings. A special feature is the design of the crankcase enclosure. This is completely oil tight, and free from oil leaks usually found in equipment of this kind.

"Feather Valves" are standard equipment on these machines, as they are on all Worthington air and gas compressors. These valves are light strips of steel, approximately 1/32 inch thick, which flex when opening against a curved guard to permit the passage of air. They probably are the lightest and simplest air valves in use.

Regulation may be by an automatic starter and pressure switch mounted on the motor, stopping and starting it to control the air pressure between definite limits. Or a pressure regulator may be attached to the compressor inlet valves, holding them open to maintain constant air pressure. Compressors with the latter type of unloader, which bypasses the air back to suction, are claimed never to overheat when unloading.

These compressors can be furnished with ball bearing idlers for short belt drive; with Texrope drives, using V-type ropes; or a synchronous motor may be directly mounted on the compressor crank shaft, thus eliminating transmission mechanism.

Witt Concealed Garbage Can

The Witt Cornice Company have brought out their new product the Witt concealed or underground garbage can.

This modern container for the underground disposal of garbage is quickly and easily installed without expense. It is out of sight, sanitary, odorless, cannot be upset and its contents will not freeze in winter nor ferment in summer.

The complete assembly consists of (1) semi-steel durable top fitted on (2) a heavy gauge, hot-dip galvanized receptacle which contains (3) a heavy gauge corrugated, hot-dip galvanized Witt garbage can or (4) a lighter gauge corrugated, hot-dip galvanized Brighton garbage can.

After each Witt concealed can is entirely finished in the black, it is hot-dipped in pure, molten zinc. The zinc (galvanizing) knits itself into the pores of the steel and will not crack, peel or chip. It averages 4¾ oz. per square foot and furnishes the rust-resisting quality so necessary for the long life of an underground can. At the same time it seals all cracks and crevices so that each inside can is water and odor tight. Unlike paint or other covering materials, this galvanizing coating becomes a part of the metal itself. Natural underground forces rapidly corrode ordinary metals. It is therefore of primary importance that cans made for such use be of rust-resisting quality.

New Stearns Conveyor System

The Stearns Conveyor Company, of Cleveland, O., a subsidiary of Chain Belt Company, of Milwaukee, Wis., recently completed a new installation at Evanston, Ill., of a coal handling system for the pumping station.

The coal is delivered by trucks, dumped into the receiving hopper from the bottom of which a reciprocating feeder delivers it to a gravity discharge conveyor which elevates it to the upper part of the silos. In one of the silos a steel cone is suspended, this design is patented. The cone and the upper part of the silo form a live storage space from which coal is drawn through a spout from the apex of the cone into a weight carrying car traveling in front of the boilers. When the live storage space is filled the coal delivered thereafter falls through the overflow spouts to the reserve storage space.

Correction

In the June issue reference was made to the A. M. Byers Co. of Birmingham, Ala. This should have been A. M. Byers Co., of Pittsburgh, Pa. The Byers Co. has been identified with Pittsburgh industry for sixty-five years.

Vol. LXXVI AUGUST, 1929 No. 8

Steel Tanks for Water Works Systems

Probable Trend in Development of These Structures

By GEORGE T. HORTON
President, Chicago Bridge & Iron Works

One Million Five Hundred Thousand-Gallon Elevated Tank Built for Royal Oak, Mich. It is Part of the Woodward Ave. Water System Project Serving a Large Section of the Detroit Metropolitan District

IN 1893 there was illustrated in the engineering press the design of a hemispherical bottom elevated steel tank built at Laredo, Tex. This structure was designed by Mr. Edward Flad, consulting engineer of St. Louis. Mr. Flad has told me that this design was entirely original. To him, therefore, should be accorded all credit for the original conception of a steel tank with a suspended bottom.

Interested as I then was in the construction of steel standpipes and in steel towers for the support of wood tanks, I could quickly grasp the possibilities in a combination of the two. It did not require any very profound calculations to show that if the upper part of the standpipe, which provides the only effective storage, could be supported on a steel tower it could be done at far less expense than that necessitated by building the standpipe down to the ground and providing the necessary foundations.

Construction in the decade following the year 1895 was in a transition stage. The elevated tank immediately appealed to some engineers; others insisted upon wood tanks; many would have nothing but a standpipe. Old records will show numerous examples of standpipes built only 10, 12, and 14 ft. in diameter, over 100 ft. high, for which was paid more than elevated tanks of approximately double the effective capacity would have cost.

Arguments as to the relative merits of elevated tanks and standpipes no longer exist. Decision is now reached upon the engineering opinion as to the best and most economical method of obtaining the desired storage.

Most Economical Form.—The most economical form of a simple storage tank—by which I mean a tank supported directly upon the ground or upon foundations if necessary—is one in which the height and diameter are approximately the same; provided the height does not exceed 50 ft. If a greater capacity is desired than can be contained in a tank 50 ft. in diameter and 50 ft. high, then the diameter only should be increased to obtain the desired capacity.

This, to be sure, is only a general statement, subject to several variable factors such as thickness of bottom and roof, allowed unit stresses, and cost of foundations.

The oil industry presents the greatest demand for storage tanks. Quite elaborate studies in connection therewith indicate the most economical height to be from 46 ft. to 48 ft. These tanks are universally built directly upon the ground, the only foundation work usually done being the removal of the top soil and leveling of the exposed surface.

I think it not amiss to call to your attention this fact, that most of the storage tanks of the world are built with so little foundation work, and that I see no reason for the construction of such extensive foundations as are usually placed under water tanks.

Elevated steel tanks of earlier years were practically all built with hemispherical bottoms. A few conical bottoms were tried out and discarded except in special instances, the most notable being those for railroad service.

One Million-Gallon Elevated Tank at Springfield, Ill. It is 72 Ft. in Diameter, Has a 17-Ft. Shell Height and a Total Range in Head of Only 37 Ft. 8 In.

The Ellipsoidal Bottom.—As demands for ever increasing capacities developed, certain inherent difficulties in the hemispherical bottom tank appeared. If we endeavored to limit the total height of a tank in order to prevent an undesirable range of head, the diameter would become so great that the bottom would be out of all proportion to the cylindrical part of the tank: for example—should be called upon for a hemispherical bottom tank containing 1,000,000 gal. and having a total height of 40 ft., the tank would be all bottom; because 1,000,000 gal. is the capacity of a hemisphere 80 ft. in diameter. The same condition would prevail in an effort to store 2,000,000 gal. within 50 ft. We obviated these difficulties, in part, by making an ellipsoidal bottom, the vertical depth of which is but half that of the hemisphere.

An ellipsoidal bottom tank answers very well in capacities up to 500,000 gal., constitutes an improvement in all sizes, and is the explanation of why so many of our large tanks have been so built. Unfortunately some of the stresses in an ellipsoidal bottom are compressive rather than tensile. These

compressive stresses in tanks of over 1,000,000 gal. capacity are of sufficient magnitude to necessitate an increase in the depth of the bottom, causing an increase in the range of head, and thus setting up a vicious cycle. More simply stated—when there is a limit to the total height of a tank, there is also a limit to the size of that tank if it be of the suspended bottom type.

It is not practical to build a hemispherical bottom tank containing more than 175,000 gallons, nor an ellipsoidal bottom with more than 300,000 gallons, the total height in each case being limited to 25 ft. While we have not as yet been called upon to build many tanks so limited, it is not unlikely that the future will bring such calls.

Advantage of Elevated Storage for Larger Systems.—Only recently have those advantages of elevated storage, known to obtain in a small plant, been considered applicable to our larger systems. (Witness the paper on this subject presented by Nicholas S. Hill at the Buffalo meeting of this association; also one presented to the Rocky Mountain Section by Donald H. Maxwell, of the firm of Alvord, Burdick and Howson; as well as many actual installations, such as those at Detroit, Charleston, San Antonio, Tampa, and others.) I am told that for such service the less the variation in head the better. Theoretically, the maximum head should also be the minimum; or perhaps better stated, the minimum head required should also be the maximum.

Pumps operate at their highest efficiency against a constant head. Pumping against additional head involves useless expenditure of energy; and where power is purchased, easily reducible to exact figures.

These conditions show that in determining the proportions of a tank, operating costs should be considered. In any city where elevated storage is under consideration, certain practical problems are at once presented to the engineer in charge. Studies must be made to determine to what extent it may be economical to limit the range of head. Once that limit has been fixed, there arises the question as to whether the storage will be better provided by the installation of many small tanks, or by fewer large ones. Very likely it will be found that the larger units are preferable; furthermore, that the size of these units will exceed the limit of any possible suspended bottom tank.

Suspended Bottom Tanks.—I imagine that there is prevalent an impression that a suspended bottom tank is the only practical—at least the most economical—form. For many years I so believed. This impression is true as regards all ordinary sizes. It is also true if the height of a tank be unlimited. Not otherwise.

The fundamental economies in suspended bottoms obtain by making use of the inherent strength in the bottom plating, and in lesser degree to the fact that a hemisphere or ellipsoid requires the least surface to contain a given volume.

The suspended bottom, due to the refinements required in its construction, is the most expensive part of a tank, and as its size is increased greater stresses necessitate heavier material. It is evident, therefore, that a point will be reached at which the additional material required in a suspended bottom will more than offset the cost of beams and girders necessary to support a flat bottom. At this point the economies in a suspended bottom tank disappear.

I have recently studied this subject sufficiently to announce that tanks over 1,000,000 gal. in capacity may be built with flat, or approximately flat, bottoms which will cost less than tanks of the same capacity with suspended bottoms. Stated more specifically, and of course referring to equal capacities, I am sure that an elevated tank with an approximately flat bottom, the height of which will not exceed 25 ft., can be built for less than can an elevated tank with suspended bottom, the total height of which will be more than 50 ft. I presume you understand that my references to the height of a tank apply to the tank only, and not to the height of the supporting tower.

There is seemingly a growing demand for tanks limited in height in order that the range of pressure may be reduced. I know of two tanks built during the past year—each 1,000,000 gal. capacity, one of which is only 8 ft. high, and the other 24 ft.; both so constructed for the reasons cited.

I think this discovery, viz., that we may radically change the form of our larger tanks from that heretofore used, to one which will reduce operating charges and at the same time effect an actual first cost saving, is most important. It will, I hope, prove of practical benefit to those members of this association who have before them the problem of elevated storage.

Acknowledgment.—The above is an abstract of a paper presented at the 49th annual convention of the American Water Works Association at Toronto, Ont., June, 1929.

New Industrial Water Rate at Fort Worth, Tex.—A new industrial rate on water was authorized in July by the Fort Worth City Council. It is for consumers "with a weighted average of 4,000,000 cu. ft. or 30,000,000 gal. per month," and on this basis will cost 12½ ct. per 1,000 gal. The table for the ordinance to be drawn covering the new schedules: For the first 350 cu. ft. $1, next 24,650 cu. ft. 22½ ct., next 25,000 cu. ft. 17½ ct., next 1,374,575 cu. ft. 12½ ct., next 2,575,425 cu. ft. 7½ ct., all over 4,000,000 cu. ft. .934 ct.

Sanitation of Automobile Tourist Camps

The safeguarding of the health o automobile tourists, both on the road and in the camps, has become an im portant public health problem. As earl as 1925 it was estimated that in 3 states there were more than 3,00 camps attended by over 2,000,00 campers. In 1928, it was estimate that, in California alone, there wer 1,400 automobile camps. In othe states, particularly those with well ad vertised scenic areas, there were prob ably several thousand others. Invest ment in camps of all kinds in the stat of Maine has been estimated to excee $5,000,000. Much has been done withi recent years to improve tourist camps but there is yet much more to do. Fo example, in one state in 1926, ther were 233 camps inspected, and only 10 of these could be approved.

The problem is not a simple one bu involves three important factors: First an intelligent understanding of th situation by the people; second, the co operation of state and local authorities and the support of official and volun tary organizations; and, third, the mos important, the fixing of the responsi bility for the maintenance of sanitary conditions.

In many states the responsibility fo the sanitation of tourist camps ha been delegated to state health officer by law, and in others, those agencie have undertaken it without expres authority. In a few states where th state agency is doing the work, part o all of the authority has been trans ferred to district or local agencies o groups. Unfortunately, there are a few sections in which the responsibilit for the work has not been positively assumed by any particular departmen or group. However, these sections ar in the minority, because within the las few years much careful thought an diligent effort has been given by healt authorities as a whole to making living conditions for campers as nearly suit able for them as possible.

Such state agencies as have started tourist camp sanitation work have usually set up regulations governing the proper construction and main tenance of this kind of camp. The three principal items in any set o regulations might be given as follows: (1) Proper camp location; (2) Safe and adequate water supply; and (3) Safe and efficient waste disposal.

What is the effect of location on a tourist camp-ground? This question might be sub-divided as follows: (1) Is the site of ample size? (2) Is it provided with a reasonable amount of shade and natural shelter? (3) Will the soil readily absorb and remove water? (4) Is the site accessible to the tourist? (5) Are utilities available from the city, and, if not, are conditions such as to permit the installation of the necessary facilities?

Latest Developments in Asphalt Paving Practice

Subgrades—Base—and Wearing Surface

By HUGH W. SKIDMORE
Of Chicago Paving Laboratory, Inc., and Craig, Skidmore & O'Brien, Inc., Chicago

A DISCUSSION of this subject should not be confined to asphalt wearing courses, because an asphalt pavement, in common with all others, must have an adequate base which in turn superimposes a subgrade, good, bad or indifferent. Bases may be of several distinctly different types structurally and likewise subgrades may, and frequently do, vary greatly within the limits of a given project. Thus we find our discussion encompassing developments in base practice and subgrade classification and treatment.

Subgrade.—Fundamentally the subgrade should be considered before the base and surfacing are designed, because the nature and bearing capacity of the soil may control the choice of both base and surfacing. Poor subgrade may respond to drainage or treatment readily and cheaply so that it will be the equal of good subgrade, or it may require such extensive treatment as to warrant spending more on the pavement and little or nothing on the subgrade. However, reasonably good subgrade support is so basic as to render doubtful its neglect in favor of expensive pavement in the vast majority of cases. There is even some doubt as to whether it should ever be neglected in the light of expensive maintenance and reconstruction in years to come. In any event, subgrade is so important that every operation depends upon its character.

One large project recently investigated, included a variety of conditions none of which has been taken into account in designing the pavement. Both top and base had followed arbitrary standards of thickness and mixture that were quite satisfactory where drainage was good and subgrade support ample, but failed miserably when conditions changed suddenly within the project.

When the Drainage Was Neglected.—A considerable cut was made at the top of a hill adjoined by a heavy fill diminishing to zero in a few hundred feet, from which point on for a mile or more the street passed through a very flat, poorly drained section in which water stands in great ponds during the spring and fall seasons. The pavement is not on a fill through this section, which means that the concrete base is saturated a great portion, if not all, of the time and especially during freezing weather. Hence in a period of only a few years, the base has failed in the cut from lack of proper intercepting drainage, on the fill from settlement, and in the flat section from disintegration of concrete due to freezing of saturated base. Cores taken from this project, together with a careful study of subgrade conditions, prove conclusively what has happened. At no point has the sheet asphalt top failed except as it has finally followed the broken or settled concrete base. Thus an asplant pavement has failed through no fault of the asphalt and a concrete base has failed because its subgrade support was not uniform in one case and in the other because it was saturated.

Obviously drainage would have eliminated this extensive failure except that caused by fill settlement, in which case the fill was too new at the time of construction. No pavement of economical design is capable of withstanding such extremely adverse conditions.

Classification of Soils.—Recent developments in subgrade investigations and soil studies have provided comparatively simple means of classifying soils with respect to bearing power and drainageability together with various means of subgrade treatment such as:

1. Porous layers on certain soils.
2. Insulating layers of fine, granular materials to prevent soft soils from working up into macadam bases, or porous sub-bases.
3. Bituminous treatment to break up capilarity, and to prevent fine soils from working up into macadam bases.
4. Compacted layers of gravel, stone, slag, etc., to correct lack of uniformity of subgrade support.
5. Drainage to remove moisture from wet areas, and to prevent wetness by intercepting flow from water-bearing strata.

Research work now in progress promises to develop much more valuable knowledge of subgrade performance.*

Base.—Pavement bases must transmit loads to a subgrade. The subgrade is essential and must finally carry the entire load of traffic. In the subgrade is good and of high supporting capacity, the base or foundation course may distribute the load over a comparatively small area without danger of rupture of the pavement base or surfacing. As the load bearing capacity of the subgrade diminishes or traffic loads increase, the foundation must distribute load over a greater area in order to avoid base failures. This becomes true, however, only when the danger point is approached, and is not an arbitrary rule, but is entirely relative to the actual capacity of the subgrade and traffic loads.

As has been shown above, correction of defective subgrade is basic, and should be abandoned only after most careful diagnosis, if at all. But even fairly good subgrades differ in capacity, so that arbitrary laws governing base type and thickness for a given traffic load cannot be laid down. Thus a thin 3-in. or 4-in. base may be ample for one subgrade, while a 5-in. or 6-in. might be required for another, etc. Likewise a macadam base may be entirely ample for one subgrade and entirely inadequately for another unless subgrade is artificially stabilized or base thickness is increased beyond possibly an economical limit.

Old Roadbeds as Foundations.—Traffic bound bases, such as old roadbeds, are nearly always excellent foundations for two very substantial reasons; they are thoroughly compacted and free from further settlement, and they are capable of carrying the traffic even though they may fail or have passed their useful period as wearing surfaces. It is because of these important economic reasons that resurfacing has become so popular. It has thoroughly demonstrated the folly of destroying a present investment for a new one of doubtful economy. Likewise stage construction, or progressive development of pavement commensurate with present needs while simultaneously laying in a store of valuable assets in the nature of future base for a surface of the first order when such shall be required, is constantly impressing more and more engineers with its soundness. Wide awake municipal engineers have recognized the economy of such development for many years, but are frequently prevented from utilizing it because of legal difficulties attending special assessment work. Several eastern states have employed it with outstanding success, likewise the state of Michigan is doing the same thing in connection with gravel and macadam roads.

Such construction marks one of the greatest of recent developments in asphalt paving practice and affords one of the most fertile fields for further progress.

Black Base.—Black base cannot be properly called a recent development; it is actually one of the oldest types of base in the country. However, in its present advanced state, it can be called one of the most important developments

*Reference is made to the valuable discussion of this subject by C. A. Hogentogler, in Proceedings of American Road Builders, 1929, and the May issue of "Public Roads."

in recent asphalt paving practice. Having been a close student of this type of construction for many years, I do not know of a single instance where it has failed of performance and that is something which cannot be said of any other type of base. True, it should not be employed in utter disregard of exact type (premixed, hot or cold, penetration, mixed-in-place, etc.) thickness, character of subgrade and drainage, but, taken "catch-as-catch-can," it has a remarkable record of performance.

Sometimes no base is required. Now and then cities find themselves the fortunate possessors of natural bases in subgrades of high supporting capacity such as gravel or sand. Where such conditions exist, advantage should be taken of these assets in designing pavement. There are numerous examples of asphalt wearing surfaces laid directly upon native subgrades of this class, which have given complete satisfaction for many years. I have in mind a certain section within the city of Joliet, Ill., where the asphalt surfacing is laid directly upon native gravel subgrade. These pavements have given excellent service for about 20 years.

Asphalt surfaces are a great protection to portland cement concrete slabs. This is perhaps the most outstanding fact developed by such experimental pavements as the Bates and Arlington Experimental Station Roads. Such surfaces protect their rigid bases against breaks following cracks in the concrete. They do not, however, prevent cracks and it is folly to expect no cracks in an asphalt pavement laid on concrete base. Soft asphalt and rich mixtures are no cure for this evil. Rich mix bases are likewise no insurance against cracking; on the contrary, tend to encourage it. Rich mix in bases is only justified in the case of persistently wet subgrades and even in these cases subgrade treatment and drainage nearly always proves to be more economical. It is well known that the richer mixes of concrete are more resistant to disintegration from freezing, hence will usually outlast very lean mixes on very wet subgrades.

One of the recent developments in asphalt paving that is increasing in great strides, is the resurfacing of badly worn and cracked portland cement concrete pavements. For this purpose, hot mix asphalt is proving to be the ideal material.

Another development in connection with concrete bases is machine finishing, leaving only a rough, grainy surface instead of the usual irregular surface. Machine finished base has the advantage of generally smoother asphalt surfaces. It is not advised, however, unless surface mixtures of good stability are laid after careful design. The city of St. Paul, Minn., has pioneered in this development with success.

Wearing Surfaces.—Undoubtedly the two outstanding developments in the field of asphalt paving mixtures are, first, rational mixture design from actual scientific basis instead of the old "cut and try" method and, secondly, the stability or shear test for rating mixtures according to traffic requirements. This test is of great value in investigation of failures, examination of materials, design of mixtures and control during construction.

Two stability tests are in use. One is the Hubbard-Field test which is adapted only to fine mixtures such as sheet asphalt. This test gives an empirical value which represents a combination of functions of the mixture under test. The other is our own test (Chicago Paving Laboratory) which measures the shearing strength of the mixture and is adaptable to all types of mixture regardless of size of aggregate.

Both tests are made at the same temperature, and for fine mixtures, upon cylinders of the same size. In our test, cylinders are increased in diameter and height as the aggregate increases in size. The Hubbard-Field results are not capable of reduction to unit stress, consequently are expressed in total load required to cause failure, hence must always refer to specimen of the same size. The Chicago Paving Laboratory shear test gives values of the basic stress that resists rutting and waving (distortion under traffic loads) and these are expressed in pounds per square inch. A fairly accurate conversion factor is possible between the two tests when applied to fine aggregate mixes such as sheet. Joint work between Messrs. Hubbard and Field and our laboratory shows that Hubbard-Field values are about 75 times ours for identical sheet mixtures.

For several years the need of a physical test for asphalt paving mixtures, capable of measuring resistance to displacement under traffic, has been badly needed. Several years' experience in both laboratory and field leaves no doubt as to the real practical value of these two tests. Since they have been in use, much valuable data has been developed concerning mixture performance. In every case of tests upon old mixtures that have given years of satisfactory service, we have found stabilities in line with those for which we are designing under similar traffic conditions today. For example, mixtures showing shear strength of 50 lb. per square inch, or better, are withstanding the dense, heavy traffic of Michigan Ave. in Chicago, whereas those showing only slightly less than this are rutting under the bus traffic.

Thus it is obvious that mixtures need not be designed in the hope that they will withstand the traffic but they may be so designed that they are certain to do so. The stability, or shear, test has done two important things that alone more than justify it as a practical test; it has exposed the fallacy and danger of attempting to increase stability by means of (a) using harder asphalt cement and (b) laying dry mixtures containing less bitumen than will comfortably fill the voids in the mineral aggregate. Extensive investigations show, first, that a 10 point drop in penetration will mean a gain of only about 5 lb. per square inch shear strength, whereas an increase of 3 per cent in raw filler, say from 15 to 20 per cent in terms of total mix, usually means at least doubling or trebling the shear strength; secondly, both decrease and increase of bitumen beyond a certain optimum amount causes a drastic falling off in stability. Hence by applying a scientifically correct test, it is easily proven that "guessing" and "hoping" for results may lead into dangerous ground—the most commonly used remedy for lack of proper stability not only failed to accomplish hoped for results, but actually harmed the mix.

Correct modern practice calls for two cardinal principles, use as much bitumen as the mixture will carry, and use a soft bitumen consistent with the traffic and actual stability afforded by the mixture. If greater stability is needed, this can readily be accomplished by manipulating the mineral aggregates, especially the filler which is the most important stabilizing factor. It is just plain ignorance to try to design an asphalt mixture around an arbitrary percentage of bitumen.

Thorough Mixing of Aggregates Important.—An important item in mixture preparation that was disclosed by the field investigations of Messrs. Hubbard and Field last summer, is the importance of thorough mixing of the aggregates before the asphalt cement is introduced. Uniformity of mixture depends upon about 30 seconds dry mix with an additional 15 to 30 seconds after adding the asphalt. The stability test proved invaluable in this investigation. The importance of such definite knowledge as this is obvious. Continued mixing at high temperature with the asphalt in thin films on the mineral, tends to harden it materially, in fact, decidedly dangerous hardening occurs of temperatures above a certain minimum, depending upon the asphalt used. Thorough dispersion of mineral once it is coated is not readily obtained, hence the importance of dry mixing with only such additional times as will accomplish thorough coating of mineral since that is all that is necessary. Thus it is seen that arbitrary long mixing periods may not only fail to accomplish the desired results but are actually dangerous.

Use of Machine Finishers.—The most recent development in the art of laying mixtures is the use of machine finishers similar to those used on portland cement concrete pavements. These machines, adapted to hot mix, have proven very successful on highway work, but as yet have not been worked out for city pavements where intersections and changing section introduces a problem. It is to be hoped that some type of me-

chanical finisher will be devised for use on city pavements.

The use of a lute on freshly raked mixture has now become almost universal, likewise the heavy three-wheeled roller for initial compression. All of these improvements not only affect quality of workmanship, but are the source of real economy.

Continued research investigations by leading technologists are not only substantiating many things that have been suspected, but are also bringing to light many new and important facts pertaining to the manufacture and laying of asphalt paving mixtures. The old order of "rule of thumb" procedure must give way to more modern scientifically correct and practically sound methods.

Problems of the Engineering Profession

Due to General Public Misconception of True Professional Status

By D. B. STEINMAN
Consulting Engineer, New York City

THE enginering profession is confronted with a number of problems arising from general public misconception of the true professional status of the engineer.

Improper Method of Engaging Engineering Service.—One of these problems is the persistence of public officials in following improper methods of selecting and engaging professional engineering services.

It is still regrettably common for municipalities or counties, contemplating some public work, to ask engineers, either by advertisement or by letter, to submit competitive bids for furnishing the required engineering services. Such procedure for engaging professional services is fundamentally wrong in principle. It virtually reduces the selection of an engineer to the basis of fee-competition. It hurts the profession by lowering its standards. It harms the public interest by placing a premium on cheapness of service rather than on high standards of professional qualifications.

Let us consider a parallel case. If you were in need of a surgeon to perform a critical operation, requiring specialized knowledge and skill, with perhaps a human life hanging on it, what course would you follow? You certainly would not ask different physicians to submit competitive bids for performing the required operation. You certainly would not go from door to door and engage the doctor who would quote you the lowest fee for the operation. You might find a raw medical graduate who would undertake the case without adequate compensation for the sake of the experience, but you certainly would not entrust it to him. On the contrary, you would seek the most expert suregeon, one of the highest standing and reputation in his field. The question of fee would be a secondary consideration. Where human life is at stake, you want the best professional services, not the cheapest.

Suppose you required legal services on matters involving millions of dollars, what procedure would you follow? Would you engage the cheapest lawyer you could find, or the best you could secure? You certainly would not call for competitive bids for the required legal services. You might secure an inexperienced or second-rate lawyer for a lower fee, but you would gladly pay the difference to retain the best legal counsel where large property interests are at stake.

Selection on Basis of Qualification.—The same principles should apply even more forcibly in the selection of professional engineers. Public officials seeking consulting engineers to design and supervise the construction of large public projects should regard it as a public trust reposed in them to select the most competent engineers on the basis of qualifications and experience, and not on a basis of fee competition. To the physician you entrust human life. To the lawyer you entrust property interests. To the engineer you entrust both: Upon his conscientious expertness and skill, the safety of both life and property are dependent.

Each profession has its standards of fees, based on the investment of training and experience and the cost of providing proper and adequate services. The engineering specialist has the same high investment of training and experience as the highest ranking physicians and lawyers. If engineers are induced to cut their standard fees by the pernicious custom of subjecting them to fee-competition, they cannot give the full measure of generous service and performance upon which the standard fees are based. The difference in fee is a mere trifle in comparison with the much larger savings which may be effected through the skill, knowledge, and efficiency of the expert professional engineer.

The custom of asking engineers to submit competitive bids for professional services probably arises from a confusion in the minds of public officials who do not distinguish between engineering and construction. The one is professional, the other is commercial. To the extent that construction work may be minutely and definitely specified, it is appropriate to select contractors by competitive bidding. But the planning, designing and specifying of the construction work represent professional services, involving the human equation, and themselves incapable of definite specifications. Two different engineers on like engagements will not give the same services, in kind or quantity. Professional work, whether law, medicine, or engineering, cannot properly be reduced to a basis of competitive fees.

The correct procedure for public officials, who wish to conserve the best interests of the communities they represent, is to ascertain through informed and impartial sources who are the best qualified engineers to handle the contemplated project. For this purpose, the National engineering organizations may be consulted. After the engineer or engineering firm is selected on the basis of such investigation or recommendations, then the amount of the fee can be arranged by mutual agreement or on the basis of published professional standards. Only by such procedure will the best interests of the public be served.

Free Engineering Service.—Another problem faced by professional engineers is the expectation or demand for free engineering services before a project is authorized or before an engineer is selected. This practice may take the form of asking engineers to make preliminary studies, surveys, estimates, and reports on a proposed undertaking, without compensation, but with the possibility of a professional engagement as a bait. Another form of this practice is the invitation addressed by public officials to engineers to submit free designs and estimates for a given project as a basis for awarding the professional engagement. Such practices are unfair, unsound, and contrary to public policy. It is an economic waste to multiply services on a given project. To base the selection of an engineer upon the comparison of uncompensated preliminary estimates places a premium upon the skimpiest design or the most elastic conscience. Such practice is conducive to subsequent disappointment or failure. Free service can hardly be expected to offer the requisite degree of thoroughness and reliability. Some one has to pay the freight. Professional men may be expected to give free services in charitable cases. But public communities and corporations can hardly be classed as charity cases. The laborer is worthy of his hire. If the services are worth anything, the engineer should not be asked to furnish them without compensation.

Instead of asking different engineers to gamble their time and money on making competitive designs and estimates, the public body should select an eminently qualified engineer in whom it has confidence, and pay him to make the alternative designs and studies of cost as a basis for any decisions and selections.

Public Fails to Give Engineer Credit.—A third problem confronting the engineering profession is a failure of the public to recognize the full scope of the qualifications and training of the engineer. On public boards, municipal councils, and planning commissions, the engineer is still generally conspicuous

by his absence. The public fails to realize that the modern engineer does not limit his work to surveying and drafting, or the computation of stresses and strains. By training and experience, and by force of the diversity and complexity of the problems he has to handle, the modern professional engineer is an expert on ecoonmics, financing, promotion, organization, and management. The modern engineer has to conceive large projects in their broadest aspects and in their most far-reaching ramifications. He has to investigate and demonstrate their economic soundness and financial feasibility. He has to organize, direct, and supervise the work of armies of men. He has to conceive, plan, and execute projects of largest magnitude. He has to exercise vision, resourcefulness, judgment and versatility beyond the requirements of any other profession.

With these qualifications, in addition to his knowledge and understanding of public improvements from the professional viewpoint, the engineer should be found in all important executive and administrative positions. The public cannot afford to have the engineer missing from public boards, councils and commissions.

Our profession has always pointed with pride to the early engineering career of Washington, and to the record of Lincoln as a land-surveyor. For the failure to elect more engineers to distinguished public office, we found gratifying consolation in the fact that two representatives of our profession had been Presidents of the United States, and that these two had been the greatest Presidents in the Nation's history. Now we can add a third name to the list, for in Hoover we have an exemplification of all that we mean today by the name engineer—a planner, an executive, an administrator. With the names of Washington, Lincoln and Hoover to inspire us, we may look forward to the day when engineers will be recognized and sought for all of the highest positions of leadership and trust throughout the land.

Latest Methods of Road Finance, Construction, and Administration Treated in New Booklet

A timely publication involving an extensive study on the subject, "Highway Construction, Administration, and Finance," is announced by the Highway Education Board, Architects Bldg., Washington, D. C.

It deals with the planning of a national highway system, with the various types of road suitable for differing traffic conditions, and with methods of financing such highway building. The studies are by E. W. James, Chief of the Division of Design, United States Bureau of Public Roads, and now on leave in Colombia assisting that South American government in organizing a road-building program. The booklet is printed in Spanish, Portuguese, and English.

"Poor roads," says Thomas H. MacDonald, chief of the United States Bureau of Public Roads, in an introduction, "cost more than do adequately serviceable roads. Roads built with honest administration and skilled technique have an earning capacity far beyond their cost. So the serviceable public highway has every right to be listed as an asset and not as an expense. It has already been well demonstrated that the highway can earn its upkeep, plus a very high profit on the investment.

"Road tolls collected in the form of motor vehicle license fees and gas taxes in the United States amount to a very large percentage of the annual highway bill, without excessive cost to the individual user. The very fact of relatively low taxes has encouraged the enormous use of the roads by so large a number of the public. This accounts for the high income from the roads in actual financial returns. It proves the value of good highways."

Recognizing that the financial problem involved in the highway program is in all countries "the fundamental and difficult one to solve," Mr. James points out that, in order to keep expenditures to a minimum, three things must be attempted:

1. To select the right roads to be improved;
2. To determine the correct types to build at any time; and
3. To build progressively, but so that all work done may be salvaged in future work.

The best method, he asserts, is "deliberately to plan a national highway system." It matters not, he adds, that pioneer roads and trails have developed, that some roads already have been improved, that cities have grown and the rural districts have been put under cultivation. Such study, he says, may disclose errors of the past and may lead to a change in location and priority of construction for many miles of highways, but if it does it saves money.

"Studies of highway systems made in the United States during the past three years," says Mr. James, "clearly demonstrate the value of such work even at a late date. But obviously the earlier in the highway history of a country such studies are made the greater good will flow from them."

The general character and condition of economic development, as revealed in data based on population, agricultural production in tonnage for general crops and in cost for special crops, such as dairy products delivered directly for consumption, and manufactured products by cost, must be surveyed, it is stated, in approaching a national or state highway plan. Other factors which must be considered include topography; existing traffic on the roads and the classification of this traffic; and the probable adequate mileage of roads in the system as a whole and in the several political or economic subdivisions thereof.

Emphasis is laid in the Highway Education Board's report on the importance of the progressive method of road building which, it is asserted, is "the only way possible to give service within any reasonable period to a state or nation which yet has most of its pioneer roads to improve."

As to financing it is declared that "roads should be built only to the extent and of such types as will pay for themselves." Every piece of construction, it is asserted, should be planned with an eye to the future and to the possibility, indeed to the probability, that a betterment of type will be required. Any highway expenditure to be justified must be earned by the road in the form of cheaper transportation, says the report, which argues that highways are fundamental requirements in a healthy, progressive, prosperous, and ambitious nation.

Fast Roads Proposed for Netherlands

The Nederlandsche Vereeniging voor Auto-Snelwegen (Netherland Association for Fast Motor Roads) is conducting an active campaign in the country for the building of through roads to be devoted exclusively to motor traffic, according to a report from Assistant Commercial Attache Paul S. Quinn, The Hague, released by the Bureau of Foreign and Domestic Commerce. Their plan is to build one road from Amsterdam, the capital and country's largest city, to Rotterdam and on the southern border leading into Belgium, another from The Hague through Utrecht to the eastern border leading into Germany, and to connect Amsterdam to the east-bound highway by a special connecting roadway between that city and Utrecht. According to present estimates the cost of this entire road plan would be around f. 200,000,000 ($80,400,000) and it is indicated that there is sufficient banking support to execute the scheme providing the Government will undertake to guarantee interest return on the investment.

The organization devoting itself to promotion of the proposed motor road plan is made up of a number of people interested in road problems including a representative from each Algemeene Nederlandsche Vielrijdersbend and Koninklijke Nederlandsche Automobielclub, two important associations devoted to automobile, traffic and roadway developments.

New Developments in Safeguarding and Eliminating Cross Connections

A Summary of New Developments in New York State

By C. A. HOLMQUIST and EARL DEVENDORF
Director and Associate Director, Division of Sanitation, New York State Department of Health

THE subject of cross-connections between public water supply systems and auxiliary industrial and fire supply systems from various polluted sources, has been much discussed and written about by leading water works and public health authorities throughout the past decade. Not alone in New York State but throughout the United States, there have been numerous occurrences of waterborne outbreaks of disease, attributed to polluted water entering the public water supply systems through various types of cross-connections.

The New York Regulations of 1925.—The Public Health Council of the State of New York after a prolonged and deliberate study of the problem of cross-connections between potable and non-potable water supplies, enacted, in November, 1925, the following regulations, known as Regulations 15-a and 15-b of Chapter VII of the Sanitary Code, requiring by July 1, 1928, the elimination of such cross-connections in New York state:

"Regulation 15-a. Certain cross-connections between water supplies not permitted. No officer, board, corporation or other person or group of persons, owning or having the management or control of any potable water supply furnished to any municipality or water district, shall permit after July 1, 1926, any physical connection between the distribution system of such supply and that of any other water supply, unless such other water supply is regularly examined as to its quality by those in charge of the potable water supply to which the connection is made and is also found to be potable. This prohibition shall apply to all water distribution systems either inside or outside of any building or buildings.

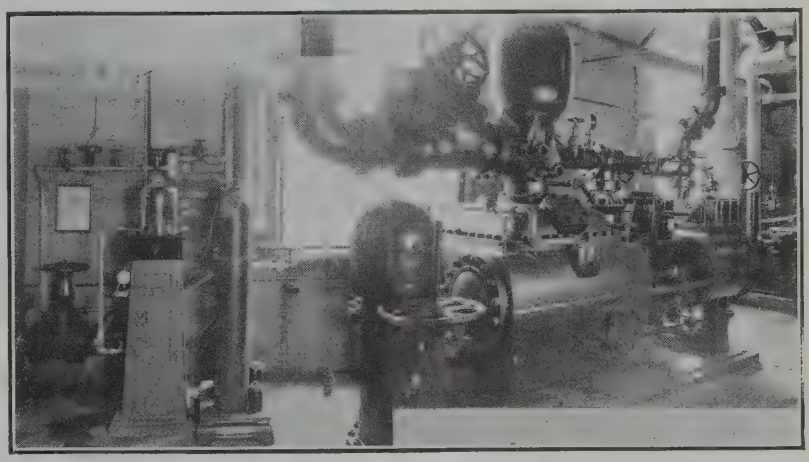
Provided, that, where such physical connections now include two gate valves with indicator posts, two check valves of the Special Factory Mutual Fire Insurance design or equivalent with drip cocks and gauges for testing, all located in a vault of water-tight construction accessible for ready inspection, the date of discontinuance may be extended until July 1, 1928.

Regulation 15-b. Permissible arrangements where dual supplies are used. If a potable water supply is used as an auxiliary supply delivered to an elevated tank or to a suction tank, which tank is also supplied with water from a source with which cross-connections are not permitted by Regulation 15-a, such tank shall be open to atmospheric pressure and the potable water supply shall be discharged at an elevation above the high water line of the tank."

Subsequent to the enactment of these regulations, protests of representatives of certain industries in the state were made to the Public Health Council. Following these protests, the council conferred with manufacturers, health officials, water supply officials, sanitary engineers, fire protection engineers and insurance organizations and held numerous hearings in various parts of the state, as a result of which the council became convinced that the severance of connections between potable and polluted water was demanded for the protection of the public health.

In view of the various hearings held and the time consumed, a great many industries had delayed taking active steps to make the necessary construction changes to conform with the regulations of the code. Accordingly, requests were received from a considerable number of industries, requesting extensions of time, due to delays, many of which were unavoidable, in having the necessary changes made to comply with the code.

Special Fire Pump Chlorination.—Moreover, in May and June of 1926, a new development in chlorination apparatus was brought to our attention which, it was thought, possibly might permit certain plants to chlorinate their auxiliary supplies and render them potable from a public health standpoint. Tests of this so-called special fire pump chlorinator equipment were made covering a period of some six weeks, as a result of which it was determined that the apparatus with proper supervision would be capable of effectively chlorinating an auxiliary supply under intermittent operation of fire pumps and thus rendering such auxiliary supply potable, provided it was only moderately polluted.



A Fire Pump Chlorination Installation

Requirements for Installation.—Such installations must, however, meet the following requirements:

1. The water supply must not be so grossly polluted that it cannot be effectively chlorinated.
2. The fire pump must either take suction from an open well or sump or there must be a municipal water supply available having a pressure at least three times as great as the pressure on the suction of the pump.
3. The chlorination equipment must be of a type approved by this department and so equipped as to continuously waste a small amount of chlorine solution and provided with solenoid or steam operated valves so regulated that immediately upon the starting of the pump it will apply chlorine at a rate of not less than 20 lb. of chlorine per million gallons of water pumped.
4. Platform scales must be provided

for checking the loss of weight of chlorine.

5. Plans of the installation, together with report and sufficient data to pass upon it, must be submitted for approval to both the local water authorities and to the State Department of Health.

6. Reports of the results of daily orthotolidine tests of the chlorine solution wasted and the amount of chlorine wasted or used per day must be submitted at least monthly to the municipal water supply authorities.

7. Chlorinators on all auxiliary industrial or fire supplies must be inspected regularly and at frequent intervals by local water supply authorities.

8. The cross-connection between a potable municipal supply and a chlorinated auxiliary industrial or fire supply must be equipped with double check valves of the "all-bronze" type placed in an accessible chamber and properly equipped for testing and inspection. Such check valves must be inspected and tested at least monthly and taken apart, thoroughly cleaned and any worn parts replaced at least yearly.

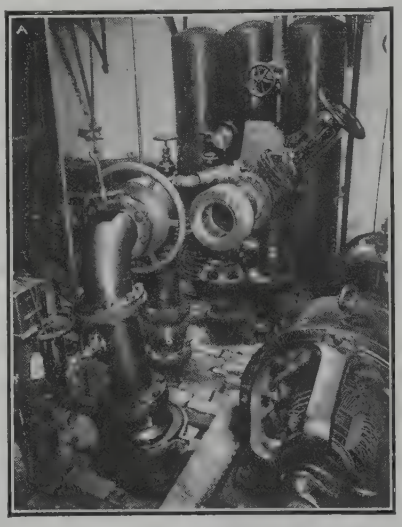
9. Discharge valves on the fire pumps must be closed whenever the pumps are turned over for testing.

10. Any approval by the municipal and water supply authorities or this department will be given only on condition that the chlorination apparatus is satisfactorily installed, operated and maintained at all times.

Results of Plant Changes.—To date there have been some 60 fire pump chlorinator installations authorized among 55 of the industrial plants of the state. A recent report of one of the insurance associations on the results of plant changes made to comply with the provisions of the code, show that out of a total of some 147 plants listed, the total estimated cost of changes necessary to comply with the Sanitary Code was about $350,000. These changes included installation of all-bronze check valves in pits, erection of gravity and suction tanks and changes in yard piping. It was estimated that the cost of heating gravity and suction tanks would be from $250 to $400 annually. It is further estimated that the fire pump chlorinators would use up approximately $110 worth of water and chlorine per year, besides the necessary supervision, making a total annual maintenance charge for the chlorinator of say $200.

There have been in some special cases, considerable expenditures necessary to eliminate satisfactorily cross-connections and at the same time provide industries with adequate fire protection. In one of these instances, the industry spent over $25,000 in placing new mains to carry the polluted water supply and thus eliminate the cross-connection with the public water supply.

Cross-Connections Eliminated Wherever Possible.—It must be borne in mind, however, that in our program of safeguarding cross-connections, it has been our endeavor to eliminate the cross-connections wherever possible. Moreover, the quality of the water supply to be treated is carefully considered and in six instances, applications for permits for the installation of a fire pump chlorinator were denied, because it was found the sources of the fire pump supplies were too polluted to permit of chlorination being relied upon. Furthermore, in all instances where fire pump chlorinators have been installed, it has been required that double check valves of the all-bronze type be installed in place of the old iron body type.



Front View Showing Swing Joint Arrangement Eliminating Cross-Connection Between City or Potable Water Supply and Emergency Non-Potable Fire Supply

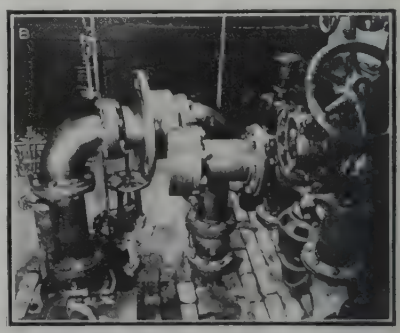
Throughout the past two or three years, many conferences and investigations have been made with public water supply authorities and representatives of industries, with particular reference to the elimination of cross-connections. In the majority of these instances some satisfactory and reasonable plan or program could usually be found for eliminating the cross-connection. In all instances, in which permits have been granted for the installation of fire pump chlorinators, the need for careful and constant supervision of the apparatus has been emphasized. In fact, it has been pointed out that should the fire pump chlorinator be neglected, the permit would be revoked and it would be required that the industry eliminate the cross-connection.

Chlorinators Operated Satisfactorily.—The earlier fire pump chlorinator installations have been in service at the time of this writing for some six months. The majority of them have been in operation at least four months. Monthly reports on the daily results of tests and observations of the operation of the chlorinators received by the department indicate that the fire pump chlorinators have, with minor exceptions, operated satisfactorily. Inasmuch as this has been an entirely new departure, it was to be expected that there might develop some features which might not be entirely satisfactory. There have been but few instances, however, where such conditions have occurred and where they have, it has been possible to determine the cause and correct the same. Although six months would be somewhat too short a time to predict with certainty the future of the fire pump chlorinator, it would appear that, given proper and careful daily supervision and maintenance, the equipment is capable of satisfactorily chlorinating an auxiliary supply under intermittent operation and render such auxiliary supply potable, provided it is only moderately polluted.

The Swing Joint Arrangement.—There has also been developed a so-called swing joint arrangement which, so far as is known, has not hitherto been employed, at least on a commercial plant size scale, to make available either one of two water supplies. By this type of arrangement, the city supply, which is normally used, can be shut off and the industrial distribution pipe line changed by means of a swivel joint to connect with the fire pump supply which, thereafter, can be placed in use. Although such a system has been approved by the State Health Department in a few instances under certain conditions, the insurance authorities have not looked entirely with favor on this type of connection, except under very favorable situations, inasmuch as it is open to the following possible objections:

1. There is a period of time during the making of the change when no water supply pressure is available.

2. Instead of having two sources of supply available simultaneously for fire fighting purposes, as is the case where both the city and the fire pump



Side View of Swing Joint Arrangement Eliminating Cross-Connection Between City or Potable Water Supply and Emergency Non-Potable Fire Supply

supplies are connected through suitably arranged check valves, there can be only one source of supply used at a time. So far as we know there have been only about a half dozen of such installations throughout the state.

Cross-Connections on Water Service Lines.—In addition to these cross-connections on fire supply lines and mill service supply lines, cross-connections have been found on water service lines for priming pumps, for boiler feed, for cooling purposes, etc., usually made for use in emergency to obviate shutting down some particular piece of machinery and frequently made for convenience or through ignorance. When such cross-connections have been discovered and the matter has been taken up both with the authorities in charge of the water supply and the owner of the property or the industry, prompt steps have been taken in all instances to eliminate these cross-connections which may oftentimes be more dangerous than the well regulated and supervised larger type of cross-connections.

Although the Sanitary Code places the responsibility for eliminating cross-connections on the local water supply authorities, the department has been called upon for advice and assistance by the local water supply authorities as the problem of eliminating the cross-connections, particularly in the case of the larger industries, involves special engineering questions. The importance of making careful inspections of piping systems at industrial plants to discover any possible cross-connections has been forcibly brought to our attention and we have emphasized to the local authorities the need for such inspections. It would appear that the painting of pipe lines in colors or with colored bands will undoubtedly greatly reduce the hazard from cross-connections made through ignorance or carelessness. Such standards are already in use in power house practice.

Careful Study of Individual Conditions Necessary.—Although conditions are found to be somewhat similar in numerous instances, there are hardly any two plants having the same hydraulic conditions and it has been found necessary to make a careful study of the conditions at each individual plant in order to determine the most satisfactory and economical method of eliminating the cross-connection. Moreover, in all cases the industries and manufacturing establishments have been advised to take the matter up with their fire insurance authorities, in order that any improvements or changes in the piping system will be made with the approval of the fire authorities.

I would be remiss, indeed, in this brief summary of the action taken to eliminate cross-connections in New York State, if acknowledgment were not made of the splendid cooperation and assistance rendered by the representatives of industries and insurance authorities. Indeed, without their cooperation, the progress already made in this very important and large undertaking could hardly have been accomplished within so short a time.

Chlorination of Pipe Lines Under Construction

By JOHN R. McCLINTOCK
Construction Foreman, Indianapolis Water Co., Indianapolis, Ind.

The company for which I work has for some time required its construction foreman to see that the pipe is not only well "swabbed" and made thoroughly free of any loose matter before placing it in the trench, but also that it is well chlorinated after being placed therein.

The process by which this is done is very simple and does not require a great amount of time. It is as follows:

Make the "first end" connection and as first length of new pipe is laid or connected to existing main, one can or container of hypochlorite of lime should be shaken into that length of pipe and at each interval of eight lengths of pipe another container should be emptied into that length of pipe and so on to the completion of line.

However, when a hydrant or a valve also is set in the main the valve may be closed and the line filled slowly from point of first connection until first appearance of water at hydrant, when the hydrant should be closed and the water allowed to stand for 30 minutes and then flushed thoroughly until no odor of chlorine can be detected in the waste water.

This facilitates the work of backfilling and flushing trenches by getting part of the new line into service. Water used to flush out pipes need not be wasted, for where economy in amount of water used is an item, it can be profitably used to flush or settle back-filled ditches.

On first thought it appears proper to make an allowance for the relative capacity of different sized mains, but we believe it more likely to be handled successfully if construction foremen are instructed to place a given quantity at the head of each 100 ft. of pipe laid and flush it out thoroughly when job is complete up to an end hydrant.

The reason for this is that for 36-in. pipe at a dose of 100 lb. per million gallons, the quantity required is 1 lb. per 100 ft. In either case it is necessary to flush the line until no odor of chlorine is detected at discharge hydrants. The removal of chlorine from the line to this degree will insure thorough cleaning by displacement alone in addition to the sterilizing effect.

While the pipe line is incomplete all openings should at all times be kept plugged, which will prevent circulation of air and thus preserve the strength of chlorine until its final removal from the pipe. After completion of the pipe line care should be taken to see that, in the removal of this treatment, none should be allowed to enter any existing line.

To get the best results it has been our method to open a fire hydrant at the furthest end of line, then to open a valve at point of beginning, letting water flow through the pipe slowly until it appears at the hydrant, shut it off for period of about thirty minutes, then open up and blow out thoroughly until the water shows clear.

At this point, reverse the operation by closing the valve and hydrant first opened and then open the valve and hydrants at opposite end of line and blow out until water is clear and free of odor of chlorine, after which open all hydrants on the line, then proceed to turn on all intersecting lines beginning at end of line from which water is flowing, still keeping hydrants open to carry out any chlorine that may have lodged in ends of branch lines and lastly open up the valve on furthest end of line.

In case there is no hydant on the end of the pipe line thus treated, it is necessary to shut off the adjoining section, opening up several hydrants first. Then open valve from new section, letting water blow out as speedily as possible that the line may be cleared of all effects of treatment before being taken into service lines of consumers.

This instruction to disinfect newly laid pipe lines should in no way, however, lead construction foremen to reduce the degree of care they have previously used in cleaning and flushing such lines.

As a matter of general information the chlorine container stocked by commercial dealers holds 12 ounces. A case of these contains fifty and costs $5.60.

In conclusion, let me emphasize the point that water used in flushing out treatment need not be all waste as it can be used to flush or settle backfilled ditches.

In case of a "dead end" where it is impossible to blow out the line, the only thing to do is to use extreme care that the pipe used therein be well "swabbed out" before being laid.

Airport Design and Construction

Fundamentals and General Details

By PHILIP R. LOVE
Of Love-Sultan, Inc., St. Louis, Mo.

PROBABLY no other phase of aeronautical development offers as fertile a field for the exercise of enthusiastic ignorance as does the selection and preparation of airports.

Aviation is neither a sporting proposition nor a theatrical enterprise, but a definitely and well-established transportation utility or agency, the widespread acceptance and adoption of which is as necessary today for a town or area anxious for continued growth as was similar acceptance and adoption of the railroads three-quarters of a century ago. Even the most casual observation compels recognition of the fact that the biggest and best cities are those with the best transportation facilities, which connect with the rest of the country and the world. Aviation is just one more transportation agency, and the city of tomorrow will grow with it or stagnate without it.

Most cities appear to realize this more or less clearly and are attempting to establish terminals or ports for the handling of this new form of transportation; but the whole development is so new, and so few persons have a comprehensive grasp of the elements and the need of ports, that much loud and vigorous effort is being misapplied.

Probably as common an error as any is the tendency to under-estimate the cost of adequate facilities. A good port is an investment in future growth and prosperity, and, in common with other things mundane, can be expected to pay return on the amount of the investment, and no more.

This error is most generally reflected in the unwise procurement of a port site on the basis of the price of the land. If a railroad desires a station site, a chain-store group a site for one of its stores, a theatre circuit site for a new playhouse, or any other business—except aviation—a site for the conduct of its activities, it considers the whole question from the viewpoint of attracting patronage rather than from the viewpoint of minimum cost for a certain-sized tract of land.

As long as flying is new in a community and offers allurement as a spectacle, people will flock to a port as to any other big free show; but as soon as it settles down—and it doesn't take long—to the routine arrival and departure of passenger, mail, and express planes flying on schedule, it must offer convenience to its potential clientele—or there will be none. The man or woman who goes into raptures over the fascination or the beauty of aerial transportation is frankly open to the suspicion of exaggerating matters, for hour after hour of flying over country which one has seen time and again is as monotonous as any other type of travel. As against this it is speedier, cleaner, and fully as comfortable as any other method, but this is soon outweighed if one has to travel long distances over indifferent roads to and from the ports at each end of the air journey.

Site Should Be Easily Accessible.—Thus it is that due consideration should be given to quick and comfortable access to town if full value is to be received from the port investment, and the search for a site should begin as close to the downtown district as possible. Nor should the fact that property happens to be occupied and used for other purposes cause it to be rejected for that reason alone, for the cost of its acquisition with the resultant scrapping of some present investment may be wholly justified by its comparative convenience of location.

Of course, it goes without saying that the fundamental requirement in the selection of any port is that of safety, for all other advantages combined cannot outweigh the disadvantage of immediate or adjacent hazards. As to what these hazards are, if one does not know and is charged with the selection of a port he had better not try to pick a site, for too many a poor devil has come crashing down in a flaming heap of shattered spars and shredded fabric on or near ports cluttered up with bordering trees, high stacks, railroad yards, high-tension lines, crowded buildings, and the like. Enough to fill many books could be written on this one phase of selection, and one could read them all and still not know the half of it. The answer is that if one has not flown in and out of ports with good ships and cranky ships, with good motors and those not so good, in good sunny weather, and in thick and blustery twilight, he should find some one who has, and then get his help.

Important Points to Be Considered in Selecting an Airport Site.—However, with a field properly selected as to availability to town and freedom from immediate and adjacent hazards, one is still a long way from a sane decision until many other points or features have been weighed. Some of the principal ones to be considered are:

Avoid an area habitually clouded by smoke or frequent local fogs. Specifically, if a town is an industrial center with soft coal as the principal fuel, or one where residence heating is done with the same material, it will be found that the side toward which the prevailing winds blow will have the poorest visibility and should be avoided. Again, a river, lake, or bay on one side of the town may occasion frequent low-lying morning fogs that will completely blanket a field or port located there, and should therefore be avoided.

Drainage.—Another thing to consider is drainage. If the area overflows with spring-flood backwater, keep away from it. Up to within the last two or three years great stress was laid on the selection of sites as "level as a floor." Today such sites are taken only as a last resort, for they require a large sum for adequate drainage—if they can be drained at all. Basically, any field should have sufficient slope at all points to preclude the pounding of water. The ideal field in this respect is one rising gently from the mid-point in the direction of the prevailing winds. This is advantageous from an operating and lighting standpoint as well as for drainage, for it offers descending grades from the rim for the acceleration of ships taking off; ascending grades for a ship landing in midfield; and better illumination of the far side of the field from floodlights placed along one side. Contrary to this a field with a ridge in the middle should be avoided in that the grades are wrong for either landing or taking off, the light from a unit along one side is cut off at midfield, and too pronounced a ridge introduces the possible hazard of collision of two planes on the ground and traveling in opposite directions.

Next, the soil should be observed or studied. A sandy loam with a good top soil is best, for it permits a good stand of turf and allows the absorption of rain, which serves to keep the field from getting muddy and holds the moisture necessary for good turf.

With all of these things watched, there will probably still be need for more or less subsoil drainage. Depending on the character of the soil and the turf, a goodly portion of the water falling in a hard rain can be allowed to flow off over the surface, but nearly every field will have some areas requiring porous drain lines of some sort. Clay or concrete pipe laid with open joints, preferably in rock-filled trenches, is quite commonly used for this purpose, but should be of good quality and laid deep enough in the ground to withstand crushing under the impact of landing planes. In addition to this the manu-

facturers of corruglated-iron pipe have developed a perforated pipe for this service. One thing which should be avoided is cast-iron or steel manhole covers or inlet gratings flush with a turf field, for the softening of the adjacent area will make sudden contact with these structures dangerous.

Another factor in connection with drainage is frost, particularly when it is coming out of the ground in the spring. This is apt to create a condition where the subsoil and subdrains remain frozen after the topsoil has become a mire. This further dictates the selection of a sloping area.

Grading and Shaping Field.—With the field selected and disposal made of the drainage problem, the next step is grading and shaping. Usually there will be some portions requiring more or less grading. In general all ridges or hollows should be lowered or filled until the gradient at no point exceeds 2 per cent. In addition to this some additional grading may be required to eliminate shadows when the field is lighted from the margin. The rows in cultivated fields generally present a formidable appearance, but are not very difficult or expensive to eliminate if attacked with the proper equipment. Disk harrows and a heavy steel drag usually work the best on these—both tractor-drawn. The best disks are the "double" type with two gangs in tandem, one deflected in and one out from the center. The first time over these should be drawn parallel with the rows, and then at right angles. The best drag which has been developed for the next step is one made of structural-steel channels laid at right angles to the direction of the travel and overlapping one another like shiplap, the slope being upward to the front with the legs of the channels standing up and the front web of each channel bearing on the rear leg of the preceding member. These are fastened to side runners—also channels—with angle clips and bolts. The whole is dragged behind the biggest caterpillar tractor available, preferably the largest made, which will handle a drag about 16 ft. across and 12 ft. long, and which will put the field in excellent condition where only a small amount of work with a road machine will be required for completion.

If there is already a stand of tough but rough or irregular turf on the field or portions of it, it may be necessary to turn this over with a plow before harrowing and dragging; while if a field of corn is attacked late in the season after the roots are fully developed, the corn should be pulled instead of cut to avoid the trouble occasioned by these roots and stubbles rolling up on the surface.

If the field was originally covered with Bermuda or other equally tenacious grasses they will generally come up through and resod the area. If not, either sodding or seeding will be required. Sodding the whole area is usually out of the question, but "spot" sodding with plants on about 3-ft. intervals with Bermuda or other running grasses will give a fair stand at the end of a full season, particularly if seed is added. If the field is finished in the fall, winter wheat, oats, or rye makes a good winter crop and mother crop for grass seed planted in the spring, particularly if 200 lb. or so of sulphate of ammonia or other good fertilizer is broadcast with the seed in the spring.

Location of Buildings.—The location of buildings on the port calls for the observation of a few "don'ts." Don't locate them where they must be crossed by planes, either landing or taking off, on the best approaches. Don't locate them where the prevailing winds will keep them full of dust from the field. Don't locate them in a low place where heavy rains will wash through them across the field, or so low that floor drains or plumbing fixtures cannot be given good outlets.

In general, locate them where good access to good roads leading from the port is economically available; locate them on some established and orderly plan with their faces or ends lying along a definite line instead of setting at various angles. If possible, leave sufficient room between the buildings and the edge of the port to permit of a proper landscape treatment, for the mere fact that an area is devoted to airport purposes does not mean that it must be ugly to be useful. Give thought in the grouping of the buildings to future use and to comfort—for instance, do not put a service or shop building where motors will roar on test night and day right adjacent to the administration building, pilots' quarters, or other places where reasonable cleanliness and quiet are desired. In other words, make the grouping along studied lines instead of allowing any and every one to put what they please where they please.

As to the detail and the character of the buildings themselves, "Costly thy habit as thy purse can buy, for the habit oft proclaims the man." A heterogeneous bunch of overgrown corrugated-iron shanties sprawling at will along the edge of the port will promptly discourage any substantial and attractive future development, and lower the value of all adjacent property as well.

In their eagerness to "get on the air map" many cities have done this very thing, excusing it with the vague apology that these are but temporary facilities, and that other and better ones will be provided "when the industry gets on a more stable basis." However, the first few buildings erected at a port generally established the character of the permanent development.

As to building materials, let these be as fire-resistant as possible, and design the buildings to permit the installation of sprinkler systems at some later date if not when they are erected. Long spans and clear areas are necessary, so the best general type of construction is steel columns and trusses and light-weight roof structures such as 2-in. tongue-and-groove wood sheathing on 7-ft. or 8-ft. spans, surmounted with a good grade of built-up roofing. Many manufacturers are urging the use of crimped steel sheets covered with fiber insulation, in lieu of the wood sheathing, but the cost is higher and there is honest question as to whether or not the thin sheets such as they urge will withstand fire and corrosion any better than wood.

Important Features of Airport-Building Design.—The structural elements of the buildings must be carefully studied and the members must be appreciably heavier than those in similar buildings located "in town" where adjacent buildings shut off much of the force of the winds, for the very nature and location of airport buildings subject them to winds with a full sweep of half a mile or more.

Another fundamental of airport-building design is to provide plenty of natural light. This means as much window area as can be obtained without sacrifice of stability or architectural appearance. Steel sash and lots of it is the best answer to this demand, and particular attention should be paid to proper design of mullions and other structural features so that they will withstand wind velocities and pressures. Also wire glass should be used for this same reason, for a properly and economically designed building will deflect and react more or less under wind action, and thin, non-reinforced glass has a tendency to break under such conditions.

Doors deserve much consideration. With the increase in wing spreads, doorways are becoming both wider and higher. Here again the wind is a real factor. On some hangars which we have built recently the doors are 120 ft. wide and 22 ft. high. To withstand the wind these doors must have the structural ability to carry a heavy horizontal load. This means heavy stiles and rails and substantial panels, with a correspondingly heavy weight per lineal foot of door. The most generally accepted practice is to make these doors of steel, and to slide them along floor tracks on well-designed wheels or rollers. Several manufacturers have designed such wheel or roller units that permit the doors to operate around corners, and this general practice is recommended.

The color of buildings should be a light shade of buff or tan—or even white—to insure the highest possible visibility both day and night.

At first, airport buildings were hard to treat architecturally, but a definite type of characteristic "airport" design is coming to the fore rapidly, and we are learning that sympathetic treatment of mass and color will give buildings a really pleasing appearance

without exorbitant cost, and the whole industry has ascended to a plane where this is not only justified but demanded. Care should be taken, however, not to lean over backward in this respect in the desire to outdo the rest of the country, for after all the flying industry is like any other industry in that it must show a profit or else fall of its own weight.

The buildings required at a port vary with its location and use, but certain specifications governing restaurant facilities, sleeping quarters, toilet facilities, waiting rooms, etc., must be observed if the port is to receive a favorable rating from the Department of Commerce. Copies of these specifications, or requirements, may be obtained from the department for the asking, so space will not be taken here to repeat them. These specifications also set forth the sizes and shapes needed on the fields themselves for the obtainment of the various ratings, and should be consulted before any other steps tending toward port selection and development are taken.

Lighting for Night Flying.—With field and buildings both prepared, there is still another requirement before a field can be given its best rating. This is lighting for night flying, which latter is increasing very rapidly, and for which provision must be made at all good ports. The basic requirements for lighting are for boundary lights at intervals not exceeding 300 ft. completely around the field; a beacon light of certain characteristics to guide the flier to the field; a ceiling projector to determine the height above ground of the bottom of the cloud ceiling in heavy weather; red lights atop all adjacent buildings, pole lines, tall trees, or other obstacles around the port; approach lights to indicate runways or the best landing strips; an illuminated wind cone or other indicator showing wind direction; and a floodlight, or floodlights, to illuminate the landing area to a certain density. In addition to this, part or all of the buildings around the port should have their sides illuminated in their entirety and their roofs wholly illuminated or with illuminated signs thereon. Definite requirements for all of this lighting are set forth in the specifications already mentioned, and these must be followed if a creditable port is to be provided.

Immediate and Adjacent Hazards.—The problem of immediate and adjacent hazards varies with the use or uses of a port. Transport planes with heavy passenger loads both come in and go out on long, flat glides, so that the approaches to a transport field should be free from any high obstructions for an appreciable distance to obviate the necessity of either coming in high or having to pull a plane into a steep climb in taking off. An air-mail or taxi field used solely or primarily for light, fast planes, and skilled pilots does not require so much attention given to approaches, for planes in this service can come in and go out at comparatively steep angles. The third type of flying is school work, and more attention must be given to the approaches of a school field than to either of the other two, for undershooting, overshooting, or stalling on too steep a climb on take-off sometimes occasions unexpected forced landings beyond the limits of a field. Unquestionably, with the increase of all types of flying we shall soon face the need of segregating the three types, particularly on account of the hazards of school flying where the green pilot has a whole day's work mapped out for him in the handling of his own craft and cannot be trusted not to cut across the bows of a heavily loaded transport plane floating in to land. If the selection of a port is for one of these specific types of flying, the approaches and general location may be gaged accordingly; but if the field is for all types of flying activities during its first months or years, it should be laid out to the most exacting requirements.

Probable Cost of an Airport.—A port wherein intelligent attention and treatment have been given to these foregoing items will cost probably at least a quarter of a million dollars for an A-1 rating, or one on an unobstructed and unpenalized area 2,500 ft. square with adequate buildings and lighting. This price tag, however, cannot be applied without study of the particular problem involved, for real-estate costs, grading, drainage, and all of the other items will vary manyfold in different locations. For instance, one field on the route of one of the transcontinental transport lines is located within a few minutes' ride of the heart of one of the largest cities of the mid-west and the property alone has a valuation of much over a million dollars, while another of the ports on which this same company is to operate, but which is located alongside a railroad right of way out in the level plains further west, is larger and better in every way, except that it is not located near a big city, but will cost but an eighth of a million in its entirety.

Unquestionably, any such amount as either of these is beyond the limit of what small cities or towns can spend. This, however, should not act as a permanent deterrent to these smaller places, for air transportation has much to offer them in its ability to connect them with the outside world, and a much smaller amount of money will provide fields or ports with limited accommodations adequate for a smaller amount of flying. With a limited amount to spend, these communities should not jump too hastily into any program, but should confer with the Department of Commerce for advice and guidance as to how to proceed.

Runways.—All of the previous discussion has been based on the development of fields of the "all over" type, or ones with their full areas turfed in a manner to permit landing or taking off at any point. In many ways these are the ideal fields and, with fair soil and drainage conditions, they will stand up fairly well under a reasonable amount of flying. With the advent of the large transport ships, however, turf fields are proving inadequate. Visualize a 5-ton truck speeding across a rain-soaked meadow at 70 miles an hour and the reason for this inadequacy is apparent. For such service hard-surface runways are needed, but these should be placed so as to interfere as little as possible with the "all over" use of the field by smaller planes. Location of these runways must be studied very carefully with due regard to prevailing winds, safety of approaches, and many other things.

Opinion as to the best materials for runways is varied. Each must be judged on its merits as to its adaptability to the prevailing soil and climatic conditions, and its economic availability. Generally speaking, it may be said that materials and applications suitable for highways under comparable conditions of soil, climate, loadings, and density or frequency of traffic are applicable to runways.

Heating.—Another feature of airport-building design that has been slighted to date is that of heating. Our organization observed and studied hangars and shops at most of the ports in the East and Middle West during this past winter. With due deference to all of them, not a single one was found that was adequately, evenly, or economically heated. Basically, a hangar is high, wide, and not particularly handsome; has terrific heat losses due to its large glass areas; and lets all out of doors come inside whenever the doors are opened to admit or emit a ship. The most marked tendency is for heat to float up toward the roof and leave the floor unbearably cold. After studying the problem from every angle the opinion was formed that the best heating would come from the installation of extremely high-velocity, large-volume, and reasonably low-temperature units in such a manner that cold air would be taken from the floor, heated to a reasonable degree, and emitted just below the bottom chords of the trusses and at angles and velocities to jet it clear across the building to impinge on the far wall where, in cooling, it would descend and travel back along the floor to the unit for recirculation. Basically, at least six air changes per hour were deemed imperative. Several of these installations are being made this spring and summer, and this time next year we shall know how well we have answered the question.

Data on Steam and Electric Pumping Stations

Comparison Between Pumping Plants of Four Cities

By J. F. LABOON
The J. N. Chester Engineers, Pittsburgh, Pa.

COMPARISONS of costs as between steam and electrically driven stations, including gas and oil where available at reasonable prices, are usually made in determining the most economical kind of power. A case in point is that of Wheeling, W. Va., where electric power supplanted steam, although coal was mined practically at the front door of the boiler house. The actual cost of this electric station was $310,000. The estimated cost of the steam station was $604,000. The fixed charges and operating expenses for 15 M.G.D. production at the electric station was $113,875, or a pumping cost of $20.80 per million gallons; for the steam station the total estimated cost was $133,000, or $24.30 per million gallons pumped.

Power is furnished the city water works under a special municipal tariff based on a guaranteed load factor specified at the beginning of the year, which gives an average power cost of 8.59 mills per kw.-hr. Slip ring motors were used in conjunction with a synchronous condenser to maintain unity power factor.

Costs at Nashville, Tenn.—Nashville, Tenn., has been rehabilitating its water works intensely for the past seven years, placing into operation in September, 1927, a new boiler house, boilers and auxiliaries. Electrically-driven pumps have been installed since 1926 to augment the pumping capacity. Figure 1 shows the results obtained under various conditions of steam pumpage, that is, with the old station operating a vertical triple expansion pump with one lift from the river to the storage reservoir; the improved pumping station with two horizontal uniflow engines operating vertical centrifugal pumps for low service, and a turbine-driven centrifugal pump on high service; and later with the new boiler plant in operation. The motor-driven centrifugal pumps are too recently installed to permit of any direct comparative data.

It will be noted that the station duty dropped off with two-stage pumpage with the uniflow and turbine-driven centrifugals in operation, but that this duty was materially improved upon installation of the modern boiler plant. Actual costs of operation have been omitted inasmuch as direct comparison of such costs with those of a similar plant might be productive of confusion, rather than good, since labor conditions and rates together with fixed charges vary with local conditions. Therefore, station duties have been given as a measure of economy, instead.

Pumpage at Erie, Pa.—Some direct comparison, however, can be made between the Nashville, Tenn., and the Erie, Pa., plants inasmuch as both involve in many respects the same types of pumps and conditions. Figure 2 shows station duties and conditions of pumpage at Erie. In this case, too, it will be seen that economies were depressed as soon as the turbine-driven centrifugal was put to protracted use, such as was the case in 1926 and 1927.

In computing station duties, the motor-driven units are not included. Their function in the figure is to show the proportionate use that is made of the various pumps, or types of power.

The Erie plant offers some direct comparison between costs of steam and electric-driven units inasmuch as a 12 million gallon motor-driven high service unit was installed in 1925 to augment the vertical triple expansion and the rest of the direct-acting steam units. Table I shows comparative costs of steam and electric power pumping at the main station.

In allocating charges for depreciation, the electric unit has been charged with the proportionate space it occupies in the station and labor required for operation. Power is purchased on a regular tariff basis. Electrical pump-

Average Rate of Power per K.W.H.—1.337 ct.

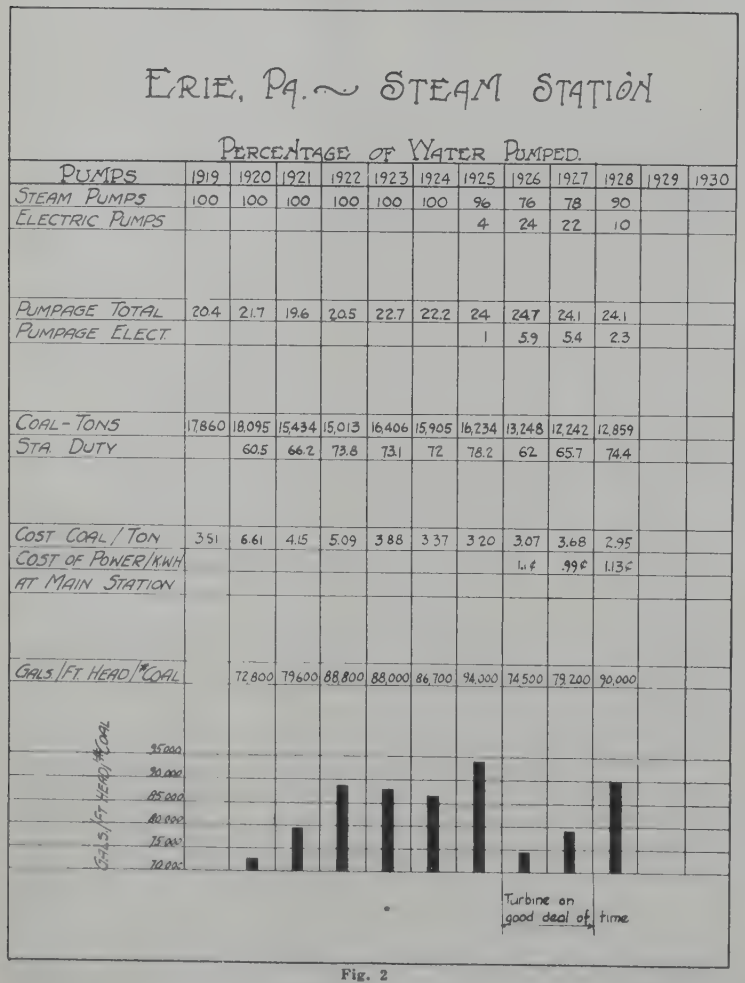

Fig. 2

ing in this case is justified by virtue of its economy. The difference in heads is due to the use of the electrical unit on Booster service head, but this difference has been wiped out by the installation of a new Booster station. The impeller of the 12 M.G.D. electrical unit has been cut back to permit of greater efficiencies at the reduced head under which the pump operates now. The pump was out of service for six months in 1928, pending the change in the impeller. Therefore, the pumpage by this unit was only 10 per cent of the total during that year as shown in Table I.

Cost of Operating Electric Pumps.—A new booster station consisting of two 5 M.G.D. and one 8 M.G.D. motor driven units has been completed to relieve the head conditions at the old station. This station has been in operation since December, 1927.

Costs and economies are given in Table II for the Booster station, electrically operated, for the year 1928.

Power for this station is costlier than that for the electrical pump at the main station, and this coupled with low head pumpage, combine to reduce economies somewhat below those found for the 12 M.G.D. unit at the main station. It is of interest to note that the new 16 M.G.D. pumping station and filtration plant now being designed for Erie, as an additional supply, will be electrically operated.

Steam Pumpage at Fostoria, O.—In contrast to the trend towards electrical pumping units as exemplified in the preceding paragraphs, is the case of the pumping station at Fostoria, O., where a study developed that it was more economical to install a cross-compound steam pump than an electrically driven centrifugal pump for high service. Table III gives the details of the comparison of costs as be-

Total	$16,300

Cost per Million Gallons—$22.50

tween steam and electrically driven pumping stations.

Power costs were computed from the regular tariff in force at the time. No saving in labor can be made with electrically driven units since the steam plant including boilers and pumps has been operated by one man per shift. New boilers were installed in 1925, so there was no need of improvement in the boiler plant, and no charge is made on this account in the comparative statement. It is interesting to note in this case that the total cost per million gallons pumped with steam equipment was approximately one-half of that for the electrical equipment. The steam station improvements were finally installed.

It is of interest to note that a few days ago the Water Department Engineers of the City of Pittsburgh decided to electrify one of its largest stations, which will have a capacity of 80 million gallons per day. Current is estimated as costing 6.5 mills per K.W.H.

While increasing use is being made of electrical power for actuating pumping machinery, fundamental principles still hold good and must be applied to every situation where the question of improving the pumping station comes up, in order that a sound decision may be made.

The Trenton Sewage Treatment Plant

Notes on the Second Year's Operation

By P. N. DANIELS,

THE outstanding features of the second year's operation of the Trenton sewage treatment plant were, first, the absence of foaming, and second, the economical disposition of the very large quantities of sludge produced.

Trouble was experienced during 1927 with all of the twelve Imhoff tanks foaming during August of the year, the plant having been started in May. At a plant of this size, design capacity 25 millions gallons per day, with 12 tanks each 144 ft. by 33 ft., control methods in practical use for smaller installations cannot be economically adapted on a large scale, particularly seeding and lime addition by solution. As the tanks had to be started without seeding, the fresh solids-ripe sludge ratio could not be established, and as a consequence, severe foaming resulted as soon as digestion was well started. Liming was resorted to from the start and undoubtedly minimized the foaming period, but the application was not as efficient as it might have been due to the fact that the lime had to be sprinkled dry over the gas vent scum and then pushed or hosed down. The installation of apparatus for thorough admixture, either by solution or return pumping of sludge was out of the question as being prohibitively expensive so that undoubtedly a certain amount of the lime was wasted and had no effect. This was demonstrated by the fact that the sludge when drawn showed many particles of undissolved lime present throughout the mass.

After the foaming ceased, liming was continued through the winter to maintain a pH of 7.3, the amount used being 110 lb. per million gallons on the average. Contrary to expectations, the advent of warmer weather did not decrease the lime demand but increased it for the maintenance of a 7.3 pH, this possibly being due to larger increments of mash from the uptown illicit distilleries in amounts so great that from ⅓-½ of the grit was rye kernels, producing, of course, very acid conditions in the tanks. It has been the policy from the start of operation to use one of the twelve tanks as a control (we are functioning at about 75 per cent of design capacity) for the purpose of studying various operating procedures and the determination of the most economical routine.

This control tank was not limed after foaming had ceased and the pH dropped as low as 6.4, but it was found that digestion, although somewhat slower than the others, proceeded in normal fashion with production of very good sludge. Laboratory tests demonstrated the same facts, so starting the first of August, 1928, no lime was added to any of the tanks, the pH dropping in all to an average of 6.6. No foaming or other undesirable effects followed, the sludge output being consistently of excellent quality.

It is not to be inferred from the above that this disproves the beneficial effects of pH control at an optimum of pH 7.3-7.6 by the use of lime where required, as the circumstances at the Trenton plant are not the same as elsewhere. In the first place, the Trenton sludge, due to the iron content of the sewage (as high as 800 ppm.), digests far more rapidly than straight domestic sludge so that we can keep the fresh solids-ripe sludge ratio at a high figure, even with a sludge capacity per capita of about 1.98 cu. ft. This feature is fully discussed by Dr. Rudolfs in another paper. In the second place, if we can obtain the desired results, good sludge digestion without disturbance of sedimentation efficiency by foaming, without the use of lime, it is uneconomic to add lime merely as an accelerant to digestion. The time will arrive with growth of population and increased sewage flow when to postpone the necessity of plant additions, it will probably pay us to expand our sludge storage capacity by more efficient digestion using lime.

To maintain this high fresh solids-ripe sludge ratio, the hoppers are kept filled to the 18 in. zone and only small quantities of sludge are drawn at any one time. The flexibility of our sludge disposal system permits this, as explained later.

So far, April, 1929, the sludge digestion is proceeding normally with no foaming even though the weather has been unseasonably warm, and from all indications 1929 will be a repetition of 1928 as far as freedom from plant disturbances is concerned. The writer is not inclined to be over optimistic, however, when it comes to predicting the future course of events at a sewage treatment plant handling a wide variety of trade wastes and will qualify the last statement by stating that we do not anticipate trouble if the sewage constituents remain as they are now. Our distillery industry is apparently on the wane, judging by mash receipts, and also by newspaper reports of a widespread "back to the farm" movement on the part of our best bootleggers. This one item, the lessening of the mash content of the sewage, is bound to help a great deal towards the maintenance of proper digestion conditions.

Another factor which assists very much is the use of lime for pH control of corrosion at the Trenton water filtration plant, started early this year. The water supply, formerly below pH 7.0 at times, is now kept uniformly at pH 8.6—this is of course reflected in the pH of the sewage and the sewage sludge.

We started to lagoon sludge by pumping from the sludge alleys to a 12-in. cast iron pipe formerly used for scum removal. This method, while a great saving over the customary sand bed drying procedure, was bothersome in that the pump had to be kept going all the time to keep ahead of the sludge accumulation. Each sludge alley (six in all) has a 4-in. connection to a 6-in. water main and it was found that by a simple rearrangement of valves we could back up the sludge enough to give the head necessary to force the sludge to the lagoon by gravity. A few trials proved the feasibility of this method and the pumping was discontinued. At the present time only enough sludge is put on the sludge beds to supply the demand from farmers, florists and others, and the rest is lagooned. No trouble has ever been experienced from this lagooning due to odors, flies, or other causes. Approximately 500,000 cu. ft. of sludge (wet) is produced yearly, per cent moisture around 89.5.

The summary of the year's activities follows:

Total flow for the year, m. g.	5,841
Average daily flow	16.0
Total expenditures	$51,000
Operating cost per million gallons gross	8.73
Operating cost per million gallons pumping	4.36
Operating cost per million gallons treatment	4.37

Valves and Hydrants

Their Distribution, Installation and Maintenance

By C. S. HOWARD
General Manager, Iowa Valve Co., Des Moines, Ia.

THE number of valves and fire hydrants in a distribution system is a field in itself, many consider, however that there should be a valve at least every 500 ft. in a mercantile section and at least every 1,500 ft. in a residential section and for reduced pressures, cross sectioned to permit free circulation and no dead ends. This is a somewhat ideal arrangement, but will be found extremely satisfactory from a maintenance standpoint, and efficient service.

Spacing of fire hydrants is usually a matter of local determination with due regard to be given to property to be protected and the saving of hose and pressure. The loss of head is estimated to be around 18 lb. per hundred feet of hose. Therefore, economy is often made in having too many rather than too few. Various rules are given: 200 ft. in mercantile districts, 500 ft. maximum anywhere.

Installation of Valves.—No valve should ever be installed without a record being made of the size, manufacture, location and cost of installation together with the date of last inspection and by whom made. We know of many systems in which the only record is in the memory of someone since removed or dead.

We know many towns in Iowa and other states, in which there is not a single record of any valve, and many in which the only valves are right outside the pump house. We know of one city in which a certain section complained of poor pressure. A new main was considered and engineers were hired. It developed that a large valve was all but closed on a supply main. Hence the necessity of records.

We also suggest here that no valve be operated by any other than an experienced man, who is responsible to either the company or fire department if a hydrant is operated.

Valves are usually made of cast iron, usually thoroughly tested to a hydrostatic test of 300 lb. factory and found perfect or they would not have been shipped. But in shipping it may have been subjected to very rough handling, so always be sure before putting a valve in the line to give it a hammer test. It may save time and money if the defect is observed before putting on pressure.

When flanged valves are used see that the fitter shows a little sympathy for the valve, and brings the pipe to the valve, not the valve to the pipe. It is not an uncommon practice for a fitter on a pipe line to use the valve bolts to draw up 2 in. or 3 in. of separation. He may get by but what about the valve when pressure is on, or if the pipe line sags months later?

When installing valves, care should be used to see that the gates are securely closed, especially with screw and flanged types; it not only keeps the dirt and grit out of the valve which might scratch the seats, but adds strength and rigidity to the valves against strain of screwing or bolting the flanges.

With screwed end types, see to it that the pipe is not too long. The pipe may ruin the valve seats. Also never permit pipe compounds to be put on the threads of the valve, only on the pipe, for if put on valve threads, it may be pushed into the valve and cause trouble and expense.

A bad practice with screwed end valves is to permit or allow the wrench to be used on the end farthest from the pipe. The strain and leverage of a long wrench may spring the valve body slightly, and thereby warp or ruin the seats. Rest assured it was all right when it left the factory; therefore, if trouble occurs, the chances are the wrench was not used on the side next to the pipe.

Packing of Valves.—Many valves are observed to leak around the packing after having been in service a considerable length of time. This is often due to lack of oil on the packing or the poor quality originally used. From our standpoint, we prefer and use a braided Italian hemp packing that has been boiled in paraffin. By adding a little graphite this seems to be durable, does not corrode the stem to any marked degree, and by adding oil to the stuffing box with a long-necked oil can once or twice a year or at the time of the yearly inspections, adds material life. Especially is this true in warm climates. As to how often a valve needs packing, seems to be a matter of how often it is operated as well as local conditions.

Maintenance of Hydrants.—I know of no better rules than adopted by New Orleans which are as follows:

1. Open a fire hydrant slowly, and steadily, and always enough to prevent any chattering of the main valve, even if more water is drawn than is required.

2. If the fire hydrant is to be left open, with pressure available for self-closing or other faucet, or valve, on its outlet, for intermittent use, open it slowly, until the hydrant is full open, then release the operating nut by one turn backwards. Where a hose bib or other connection is placed on hydrant, care must be used to see that rubber gaskets are placed under the nozzle caps.

3. Close a fire hydrant very slowly, especially as the valve approaches its seat, until it comes firmly to its seat, and then release tension on valve and stem by one turn backwards of operating nut.

4. After closing a fire hydrant, see that the caps are properly replaced over its outlets.

5. Do not allow a fire hydrant to run for gutter flushing after the flow in the gutter becomes reasonably clear.

6. Use no tools to operate a fire hydrant other than a close fitting five-sided wrench furnished by the Sewerage and Water Board. If wrench becomes worn, so that it injures the operating nut, turn it in and obtain a new one in its place.

In the city of Akron, O., which I believe was the first city to put the hydrants in charge of the Fire Department, men are regularly sent from each department to inspect, operate and report the condition of each hydrant. No one is allowed to open a hydrant, but a fireman who is available for duty when called by contractors, etc. His time is then charged in the service by the water company.

In these days of automobiles, trucks and wild drivers, every fire hydrant should have a valve between it and the main. When a line has 80 lb. or more pressure and the hydrant is broken and spouts, of what use is a valve set directly in front of the hydrant. You can't get at it to close it off. Therefore, have the valve in the street not inside the curb or next to the hydrant.

Inspection of Hydrants.—Hydrants besides being systematically inspected at least every spring and fall should further be inspected after use, during the winter by a competent man, familiar with its construction and operation.

Every hydrant to be properly installed should rest on a solid stone or concrete base preferably broad at rear and have coarse gravel, bricks or the like, but no ashes, dumped around the base, then on top of this, straw should be placed. The reason for this straw is that in back filling by water the straw collects and prohibits the dirt from packing into the gravel and thereby permits ready drainage from the hydrant. Many cities connect every hydrant drain with the sewer. Where roots are liable to creep into the drain barrel of the hydrant, it may also be desirable to dump rock salt or copper sulphate in with the gravel. I have seen hydrants completely put out of commission because of roots.

However, salt in certain soils is very hard on cast iron so care should be used to prevent its coming in contact with the iron. For this reason, use of copper sulphate is strongly urged, although more expensive.

Hydrants, if properly installed, used and inspected, should last for years, for they generally wear out from abuse rather than use.

Acknowledgment.—The foregoing is an abstract of a paper presented to the second annual Iowa Water Works Conference.

The East Side Sewage Treatment Plant of the City of Topeka, Kan.

Exemplifies Many of Recent Developments in Sewage Treatment Practice

By CHARLES A. HASKINS
Consulting Engineer, Kansas City, Mo.

THE East Side sewage treatment plant of the City of Topeka, Kan., now under construction, is of such a type that a description of the features of the plant will illustrate many of the recent developments in sewage treatment practice. This plant is designed to serve a population of 54,000 with an average daily sewage flow of 5.4 million gallons. Part of the sewer system is on the combined plan, but the bulk of the storm water will be bypassed directly into the Kaw River. The dry weather flow of the existing outfall sewer will be collected by an interceptor and conducted to a pumping station, from which it will be pumped through about 500 ft. of 30-in pipe to the treatment plant.

This plant is being built for primary treatment only, though it has been so arranged that activated sludge units can be added in the future. It is of the separate sludge digestion type. The units of the present plant include a bar screen, grit chamber, two 70 ft. square settling tanks, two sludge pumps, two 65 ft. circular sludge digesting tanks of the closed type, 28,800 sq. ft. of sludge beds, and a general building which houses the sludge pumps, the sludge heating equipment, the bar screen, and the grit chamber mechanism. The building also provides office laboratory, garage, shop. and storage space, and toilet conveniences for the operators.

Bar Screen.—At the plant the sewage will pass first through a bar screen having ½-in. openings. This screen is of the Dorr type, mechanically cleaned by a revolving rake arm, the screenings being deposited on a perforated drainboard. From this drainboard the screenings will be hand raked at intervals into a galvanized iron chute and will fall by gravity into a gas fired incinerator located on the floor below the screen unit. The incinerator may be run continuously or intermittently as the volume of screenings requires. Both the screen and incinerator are housed in the general building.

Grit Chamber.—After flowing through the screen the sewage passes into the grit chamber. This grit chamber is of a type very recently developed by the Dorr Co., and is known as a detritor. The detritor consists of two essential parts, a settling tank with grit collecting mechanism, and a washing compartment with grit cleaning and discharging mechanism.

The settling tank is of concrete 26 ft. square and with a water depth of about 2 ft. at normal flow. The sewage enters along one side through a series of gates which are made adjustable for the purpose of distributing the flow evenly over the tank, flows across the tank and out opposite side over a sharp crested weir running almost the full length of the side, and into an outlet channel, from which it is conducted through pipes to the main settling tanks. The grit collecting mechanism consists of four radial raking arms on the floor of the tank, suspended from an oscillating truss, one end of which is pivoted on a pier at the center of the tank, and the other end of which is propelled by a motor along a rail which runs around the periphery of the tank. In operation, the radial raking arms sweep the settlings toward the outside of the tank, and at a point on one side of the tank they are forced into a chute leading to the grit cleaning compartment. This cleaning compartment is an inclined trough built against one side of the tank proper. It is 15 in. in width and about 25 ft. in length. Since it is inclined, the lower part of it is below the water surface, while the upper part is above the surface. The cleaning mechanism consists of a series of reciprocating rakes hanging in the trough, and supported from above. These rakes move the settlings up the inclined floor of the clearing compartment to a discharge point at the upper end. During this movement up the inclined floor, a rolling action is imparted to the settlings, and since they are under water during the first part of the travel, there is effected a separation of the heavier grit and the lighter organic matter. The organic matter is conducted back into the tank through a bypass from the cleaning trough.

This unit is a very recent development, and information on actual operating results are very meager. The machinery, however, is practically the same as has been used for some time in mining and metallurgical operations and is well worked out as to details. A unit of this type, designed to handle 2.5 m.g.d. has been in operation for more than a year at Harrison, N. Y., and is removing 90 per cent of all grit over 100 mesh, with only 2.5 per cent of putrescible organic matter left in the grit.

The mechnical washing of the collected grit seems to be a decided advantage. The chief trouble with grit chambers is that, in order to catch the grit at times of high flow it is necessary to have very low velocities through the tanks at normal flow, and most organic matter is settled out with the grit. In the Topeka installation the velocities through the tank will vary from 0.2 to 0.4 feet per second, and some organic matter will no doubt be settled out, but will be later returned to the sewage from the washing compartment.

A novel arrangement has been provided for the removal of the grit from the site of the plant. At the upper end of the cleaning trough the grit is dropped into a hopper the bottom of which is about 5 feet below the surface of the water in the outlet channels of the main settling tanks. A six-inch pipe is laid from the outlet channel to the grit hopper, and a four-inch pipe from the bottom of the grit hopper to the outfall sewer, about 10 ft. below the hopper. Water will be allowed to flow from the outlet channel of the settling tank to the grit hopper, and flush the grit into the outfall sewer. The velocities of flow in the outfall sewer will be as high as those in the force main coming to the plant, so the sewage should be able to carry away all the grit it has brought to the plant.

Settling Tanks.—There are two settling tanks 70 ft. square and 8 ft. deep, equipped with Dorr traction type clarifier mechanisms. These mechanisms consist of radial sweeping arms on the bottom of the tank, suspended from an oscillating truss which is pivoted at one end of a pier in the center of the tank, the other end being propelled by an electric motor along a rail on top of the walls of the tank. The oscillating truss extends itself as the propelling mechanism approaches the corners of the tank, which are slightly rounded, and shortens again as the mechanism leaves the corner. The raking arms at the bottom of the tank sweep the settlings into a sump at the center of the tank, which is tapped by the suction pipe from the sludge pumps.

These clarifying tanks are designed for a 2½ hours' detention period. The sewage flows along one side of the tank in a channel designed to keep a constant velocity at all points, and enters the tank over weir plates extending over about 70 per cent of the width of the tank. After flowing across the tank it discharges over similar

weirs into an effluent channel leading to the outfall sewer. These weirs are in 6-ft. sections and are all adjustable.

In an effort to prevent any accumulations of floating matter on the surface of tanks, it was decided to omit all baffle walls, leaving an unobstructed water surface from the inlet to outlet. It is possible that there may be some circuiting or streaming effect across the surface of the tanks, in which case provision is made for the installation of baffles.

Digester Tanks.—There are two circular digester tanks, 65 ft. in diameter and 23 ft. deep, equipped with Dorr sludge agitating mechanism. The tanks are designed to provide a sludge capacity of 2.5 cu. ft. per capita. The floors of the tanks slope slightly toward conical sumps in the center. From these sumps 10-in. sludge lines lead to the sludge beds, and 6-in. suction lines lead to the sludge pumps in the building. These suction lines are provided so that the sludge in the tank may be circulated by pumping.

The sludge agitating mechanism revolves on a central shaft suspended from a truss bridging the tank, and consists of radial scraping arms for stirring the sludge at the bottom of the tank, and radial arms near the top of the tank for keeping the scum broken up.

An overflow is provided for carrying off some of the supernatant liquor in the tank when fresh sludge is being added. This overflow leads to an outlet beneath the surface of the water in the detritor tank. Means are also provided for drawing off any scum which might collect in the gas domes.

These tanks are equipped with concrete covers and gas domes for the recovery of the gas formed by the digestion of the sludge. The gas is piped into the general building where some of it is used in the incinerator for burning screenings. The bulk of the gas, however, will be burned in water heaters and the hot water circulated by pumps through pipe coils inside the digester tanks for the purpose of keeping the digesting sludge at a temperature favoring rapid digestion. The building will also be heated by the hot water. A daily production of about 30,000 cu. ft. of gas is expected when the plant is loaded to the designed capacity.

Sludge Pumps.—The two sludge pumps, for pumping the settlings from the clarifier tanks into the digester tank, are located on the main floor of the general building. They are diaphragm pumps of the Dorr type capable of handling 50 gal. per minute of 95 per cent moisture sludge each. Six-inch suction lines lead from the bottom of each of the clarifier and digester tanks to the pumps and 4-in. discharge lines lead from the pumps to the tops of the two digester tanks. These suction lines come together in a header located in the sub-basement of the building directly below the pumps. The suction and discharge pipes are so arranged that it is possible to:

1. Pump from either clarifier, with either pump, and discharge into either digester tank.

2. Pump from the bottom of a digester tank into the top of the same tank.

3. Pump from the bottom of one digester into the top of the other digester.

4. By an easily completed cross connection, it is possible to flush out any of the suction or discharge lines with city water under pressure.

5. All the suction lines enter the basement and terminate in wye branches, the branch of the wye leading to the suction header and the straight part being capped with a blank flange. By removing these flanges it is possible to rod out any of the suction lines, as they are laid perfectly straight.

Considerable thought was given to the layout of this piping and it is believed that an arrangement has been obtained which will allow of considerable flexibility in the operation of the various units of the plant.

Sludge Beds.—There are no unusual features about the sludge beds, but it is believed they are in line with the latest practice. There are 8 beds each 30 by 120 sq. ft., grouped together, providing 0.5 sq. ft. per capita. The sludge lines leading to the beds are so arranged that the sludge from either of the two tanks can be discharged on to any one of the eight beds. The filtering material consists of 6 in. of sand and 12 in. of crushed rock underdrained by lines of 4-in. tile at 5 ft. centers, laid with open joints. For removing the dried sludge, an industrial railway with push cars is provided. A main line is laid along one end of the battery of beds, with a turntable and stub track leading into each bed. Final disposal will be made by filling in several acres of land adjacent to and 10 ft. below the general level at the plant.

Appearance.—Since the plant is located adjacent to a residence district an effort was made to effect a pleasing appearance. All units are so arranged that they are symmetrical about the center line of the plant, and the earth grades and drives have been worked out so as to set the structures off to best advantage. There will be no overhead wiring about the plant, it all being carried in undeground conduit. When the plant is completed an effort will be made to get the city to beautify the grounds with grass and shrubbery.

Odor Control.—In the design of both the pumping station and the plant, the question of odor control was very important, as both units were of necessity located very close to residence districts.

In the pumping station an attempt was made to prevent the settling out of grit and heavier organic particles in the wet well, which is usually a serious source of odors. The floor of the wet well is to be formed into well defined and fairly narrow channels, so that when the sewage is drawn down near the bottom it will flow in these channels to the pump suctions with enough velocity to scour the bottom clean. Arrangement is also made to chlorinate the sewage at the pumping station, in order to keep it in a fresh condition while it is passing through the plant.

At the plant all reasonable precautions are provided for eliminating odors. Screenings and grit which are removed from the sewage will be disposed of promptly and in an inoffensive manner. The settling tanks have been arranged to prevent, as completely as possible, the accumulation of floating matter. Baffles have been eliminated and all corners likely to collect and hold deposits have been filled in. The digesters are of the closed type, and all gas issuing from them will be burned. The sewage is conducted about the plant, not in open conduits likely to collect deposits, but in underground pipes. Hydrants are provided about the plant furnishing city water for flushing and cleaning.

The fact that modern practice makes for the better control of odors has been a real economic advantage at this plant. Had it not been possible to control the odors so closely the plant could not have been located at its present site, and the next available site is about a mile farther from the pumping station. The use of the farther site would have added about $50,000 to the cost of the force main.

Chlorination.—It will be necessary during periods of low flow in the Kaw River, to chlorinate the effluent from this plant for the purpose of relieving the load on the water treatment plant at Lawrence, about 30 miles downstream. The sewage will also be chlorinated at the pumping station for the purpose of reducing odors at the plant. Since there will be a considerable consumption of chlorine, it has been arranged to handle the chlorine in drums containing one ton, instead of the small 150 lb. containers. This will effect a saving of from 35 to 40 per cent in the cost of the chlorine, and also a considerable saving in freight. The advantages of using chlorine in ton containers are well worth considering in any case where a large quantity is to be used.

Acknowledgment.—The above is an abstract of a paper presented before the Missouri Water and Sewerage Conference.

Aberdeen, Wash., May Buy Local Railway.—Legal proceedings leading to the acquisition by the city of the Grays Harbor Railway, Light & Power Co. of that district have been authorized in a communication from the city council granting to Mayor H. E. Bailey power to employ special counsel and to proceed with the necessary steps to procure the facilities.

Ethics for Engineering Services

By NICHOLAS S. HILL, JR.
Consulting Engineer, 112 East 19th St., New York City

UNQUESTIONABLY, one of the most gratifying changes which has taken place with respect to the engineering profession during the last century is the recognition of the fact that the engineer is not purely a technician, but that many engineers are endowed with broad common sense, judgment and executive ability. Whereas formerly men serving in public office, on national and state commissions, or selected as the executives of large corporations were drawn almost exclusively from the field of business and the legal profession, it is very common to see engineers selected at this date, and there is reason for this, for no training serves as well to fit a man for executive work, if he has innate executive ability, as the training of the engineer. The recent attempt, however, of engineers to push or promote the engineer for executive or public positions, just because he is an engineer, is in my judgment erroneous, because that is a matter of individuality. The engineer with the qualities and equipment necessary for an executive and with a leaning towards executive or public work will gradually emerge from the practice of engineering into executive fields, and will command the same respect and attention as a man of the same qualities and equipment who emerges from the profession of the law or medicine.

In saying this I do not wish to belittle the professional work of an engineer. On the contrary, there is a grave question in my mind whether the professional work of an engineer, although possibly it does not bring the same emoluments, is not equally as important and as meritorious as the work in the executive field. Notwithstanding this fact, the engineering profession must recognize that as the profession grows and this country is stabilized there is going to be a greater and greater demand for executive engineers, and the educators in our engineering schools should, in designing their courses, bear this fact well in mind.

Engineers as Voluntary Advisers.—It may be well in this connection to call attention to the pitfalls which await the engineer when he assumes the responsibility of a voluntary adviser in civic affairs.

When working by himself and entirely on his own initiative the engineer who takes up civic questions is likely to be cautious in his public utterances and to confine himself to fields in which his personal knowledge, experience and professional reputation qualify him to speak or write. On civic committees, however, the engineer is only too prone to go into fields outside of his own and presume to speak or write without authority. This is a mistake, and an injury to the profession, particularly in the event specialists are employed to advise with committees on which he may be a member. It is only in cities of considerable size, and not always then, that local engineers are available to deal authoritatively with highly specialized subjects. Whenever an engineer or engineering committee, not provided with funds to call in someone who is really expert on the subject in question, assumes the responsibility of giving advice, there is always a danger of serious error, and there is also the danger resulting from the fact that the average citizen is apt to think that an engineer is an engineer no matter what the questions involved, and because an engineer or group of engineers in their midst is willing to supply information and advice gratuitously it is quite unnecessary to engage engineers and pay them for detailed engineering services. The engineer can do no greater service to his profession than frankly to admit his lack of knowledge on specific questions. He does not hurt himself by so doing, for no engineer can be expert on all subjects. When an engineer serves on public committees which have to deal with technical questions he can perform no greater service than to advise his fellow citizens of the necessity of securing expert advice. The medical profession is far and away ahead of the engineering profession in this regard. The doctor does not hesitate to advise calling in a specialist and by so doing he does not feel that he is depreciating himself in the eyes of his patients. In fact, the very act of calling in expert assistance ennobles the profession. It leads the public to have confidence in the engineer and the engineering profession as a whole. The future development of engineering depends largely on an appreciation of the responsibility of the individual engineer when he accepts service on public committees. It is desirable that the engineer should be public spirited, but he may, unfortunately, do a great injustice to the profession unless he appreciates the necessity of expert advice.

Utility Management and Finance.—A great field of usefulness for engineers has developed with the growth of municipally owned utilities, particularly in the field of water works management and financing. The rapidly growing percentage of engineers on water works staffs is pleasing because it shows an increased recognition of the value of engineering in this field. The public water supplies of this country are in general municipally owned, but they have an enviable place among public utilities.

How are our public water supply systems to attain even higher standards than have been maintained in the past? The answer is: More efficiency in administration, finance and operation, as well as sound engineering design and construction. In saying this, the importance of sound engineering is not to be depreciated, for that is vital. What the water works of today needs most, however, is freedom from partisan politics and independent administration. Freedom from politics can be obtained by the education of the public and proper city charters which isolate the water department and treat it as a utility. The success of any business enterprise depends upon its conformity with the fundamental laws of political economy. The United States Supreme Court and other courts have held that when a municipality engages in the water business it conducts a commercial enterprise and is subject to the same rules at law as a private company engaged in the same business. The water department should, therefore, be maintained as a separate entity and be made responsible for the establishment of rates which will secure the revenue necessary, not only for its operation, but for financing new issues of securities necessary to meet the development of the service. All water revenues should be returned to the water department and applied by it to the needs of that department. In other words, the water works should be self-supporting. Water revenues should not be robbed for the benefit of other city departments and the water service thereby crippled. To rob the water department in this way is not only precarious, but is unjust to the water consumer, who should not have his water bill increased to ease taxes for sewers, pavements, or other purposes. Engineers as a whole, I think, recognize this principle, and the members of the American Water Works Association can do a great public service by helping to educate the public to an appreciation of the necessity of treating municipally owned utilities as private utilities would be treated.

The Engineer and the Contractor.—The laws of most states and municipalities require that public contracts should be awarded to the lowest responsible bidder. This, no doubt, is the outgrowth of the lack of public faith in the public officials of the past. Every one of you must recognize that serious trouble could be avoided and better work secured if municipal officials could call upon qualified contractors for special work, but, unfortunately, such dis-

cretion vested in official bodies has been abused in the past. Whether the abuse which would arise from allowing the municipal engineer to select qualified contractors for specific work outweighs the municipal losses sustained by the rule of awarding to the lowest responsible bidder is seriously to be doubted.

A great improvement in the integrity and honesty of municipal officials has developed in the last two decades, and everyone knows that the rule of awarding to the lowest bidder requires that the city officials be prepared to deal with the man who submits the lowest estimate for the work to be done, irrespective of his proficiency. As a result of this condition, it has been absolutely necessary that contracts be so drawn as to give the engineer the whip hand when he is forced to deal with unqualified or unscrupulous contractors. Many of the contract clauses which appear excessively harsh are a direct reaction from this method of letting work.

The engineering profession, by upholding a high ethical code in its membership, can re-establish the public confidence in city officials, and by so doing make it possible to deputize to the city officials the discretion necessary to secure competent contractors for public works. If this were done, many of the contract clauses which are now found in all municipal contracts could be toned down. Such a modification would not only be of benefit to the municipalities, but would be a decided advantage to responsible contractors.

I am a hearty believer that the engineering profession can accomplish a great work by giving the contractor a square deal, and anything that tends in that direction will be beneficial not only to the contractor but to the profession and to the clients represented by the profession. What I desire above all things to bring to your attention is the failure of many engineers to give the contractor a square deal, to tell him fully and openly what they know of the conditions surrounding the work which he is to perform, as well as what they do not know, to the end that he may judge for himself concerning the risks and uncertainties of the proposed work.

I would also appeal to engineers to assume their own responsibility, to take the blame where they are to blame, and not to fall behind the broad but stringent clauses found in most public works contracts.

The reactions against these clauses are found in recent decisions of the courts. More and more the courts are finding that the mere writing of a clause in a contract does not make it binding, that a contract is based on equity, and that the contractor has rights as well as the owner. As a matter of fact, contractor and owner have a joint interest, namely, to do the work required as cheaply and as well as possible, and it profits no engineer to indulge in sharp practice upon the contractor. On the contrary, it profits him to help the contractor as much as possible. These principles have been recognized for years past, and yet how frequently we find the rulings of engineers on the interpretation of contracts and specifications overruled by the courts to the loss and detriment of the owner.

Such conditions not infrequently are the indirect result of competitive engineering bidding, and constitute one of the evils which follow in the wake of this practice. Engineers who fail to ask for the compensation necessary to enable them thoroughly to make preliminary investigations and prepare plans and specifications based on accurate data not only hurt the profession, but do an injustice to the contractor who bids on incomplete plans and specifications, and as a result thereof exposes his client to loss. May I ask this association to help in this regard?

Engineering Ethics.—It is pertinent to ask whether the ethics of our profession has developed to the same extent as has the practice of engineering in the last century. I don't know how you feel about it, but it appears to me that unless engineers unite and insist upon high ethical standards in the practice of their profession, it is doomed to ultimate commercialism.

It is perfectly true that as this country develops it becomes increasingly difficult, nay, wellnigh impossible, for the engineer to develop a private practice by hanging out a shingle and awaiting the advent of clients seeking his services. On the other hand, there is no reason why the approach of the engineer seeking new engagements should not be professional, dignified and reserved, and there is no reason why he should in any way lower the standards of his profession or do injury to a brother engineer in so doing.

A custom much to be condemned and which, if not corrected, will certainly react detrimentally to the profession, is to be noted. I refer to competitive bidding.

Nearly all of the professions recognize that it is unethical to compete with a fellow member for employment on the basis of professional charges by reducing his usual charges and attempting to underbid his competitors. Yet this is growing to be quite common among engineers.

Recently the city of Saratoga invited competitive bids for engineering and it was surprising to see that a number of engineers responded. A year or two ago Los Angeles felt called upon to advertise for outside engineering work and to award it to the lowest bidder. Even the Port of New York Authority some time ago extended an invitation for proposals to carry out certain important bridge designs. It called for bids on price and time of delivery of expert engineering services, services involving a very high type of specialized engineering skill and trained judgment, in precisely the same way that one would ask for price and time of delivery on coal or brick. This, so far as I know, is the first time a responsible and well informed public authority has resorted to the bidding system of selecting a professional man to direct the expenditure of large sums of public money.

This is bad professional practice, the evils of which are sufficiently self-evident to require no argument or proof. It is difficult to see any justification for it, and engineers who have regard for their profession certainly should not help such practices by submitting bids for engineering services.

I am sure that the men of the old school of our profession would have scorned such a proposition, and I think it is up to associations like this to combat the tendency by making it apparent that members who participate in such practices are not welcome to the profession.

It may not be amiss at this point for our own edification to dwell for a moment upon some of the older men of our craft with whom as youths we were associated, and to recall the dignified poise of their bearing, the outward sign of an inward consciousness of right doing which resulted from long years of sacrifice to their calling, to remember their rugged, simple characters, their allegiance to accuracy and truth, and devotion to duty growing out of a love of their profession and the lack of desire for personal gain, and ask if the profession of today is actuated by the same high motives. I leave you to make answer.

Engineering Fees.—We find much complaint among engineers of the small remuneration which they receive. How can the engineer expect consideration from the public and a proper appreciation of his services when he depreciates his own services by failure to uphold the ethics of his craft? Conceive, if you will, of a body of lawyers submitting competitive bids for legal services, or a group of doctors bidding for the cure of a case of illness or for performing an operation. No one would dare approach a lawyer or a doctor on any such basis, and there is no more reason why the engineer should be approached in this way than the doctor or lawyer, and it will not be until the engineer has a full sense of his professional dignity and of the value of ethics in his profession that it will be recognized and respected as other professions are.

Acknowledgment.—The above is a paper presented June 20 at the 49th annual convention of the American Water Works Association.

Concrete Pavement Over Poor Subgrade at Port Newark, New Jersey

Unusual Design for Paving on Fresh Hydraulic Fill of Clay

By CHESTER MUELLER
Principal Assistant Engineer, Department of Public Affairs, Newark, N. J.

The principal reasons leading to the adoption of an unusual concrete pavement design in Newark, N. J., were:

1.—The character of the subsoil and underlying strata.

2.—The presence of surface water in quantity.

3.—The lack of time, limiting the operations preliminary to paving.

Due to the dearth of adequate and conclusive information on sub-grade preparation and the many advances made in concrete pavement, the developed design is a mixture brewed of theory, experiment, and experience.

History of Paving Site.—The 22,000 sq. yd. of pavement designed to meet the conditions enumerated, were laid in the spring of 1926 at Port Newark, in response to the sudden demand for streets imposed by the rapid port development. A brief history of the paving area, which fronts the ship channel and extends about 1,500 ft. inland, will provide a background for the description to follow.

Originally, the entire area consisted of a flat level expanse of salt meadow at a general elevation of 5 ft. above mean low water. An average tidal range of 4.7 ft. kept the soft, spongy humus habitually moist. In 1917, as part of a development started several years previously, this area was raised to an elevation of about 8.5 ft., using material dredged from Newark Bay. In 1921, additional hydraulic fill was placed to an elevation of about 12 ft. Compaction and settlement of the fill and underlying strata required still more material three years later in order to maintain the elevation of 12 ft. In 1926, there was, on an average, a 9-ft. layer of clay fill the surface of which was at an elevation of 11 ft. above mean low water.

A number of wash borings in the paving site, revealed material clearly defined, but varying in thickness. The bed-rock, about 75 ft. below the surface, is a sedimentary shale of the Triassic formation common to Northern New Jersey. The 50 ft. of material (clay and sand) immediately above it, is part of the post-glacial drift. Next above this is a 10-ft. layer of mud and silt deposited by the waters entering the vast lake or bay once covering the area. Topping this layer is 5 ft. of humus, the result of the growth and decay of centuries of salt-marsh vegetation. This original soil is now covered by an average 9-ft. layer of dense red clay, hydraulically placed. Possessing all the disqualifications of clay as a sub-base, this upper layer presents the principal problem for successful road construction. A secondary, but no less important, consideration is the plasticity of the layers just beneath.

Observations and Tests on Sub-Grade.—Some observations that directly or indirectly throw light on the character of the soil and sub-grade were made.

Water Content.—When the dredged material was pumped in, two features were noticeable. In the first place, most of the material was in a finely divided state held in suspension by the water, causing the fill to resemble a quicksand for months, or until the drying out was complete. In the second place, numerous rounded masses, "balled clay," came through the pipe line. On examination, the cores of these masses were found to be perfectly dry. These features in themselves are not unusual in dredging experience, but they typify the impermeability of the clay fill.

After the fill had dried out, it was hard, compact, and apparently impervious to water. A rainfall, however, converted the area into a veritable sea of mud, causing water to stand for some time and softening the soil thus immersed to a depth of from 6 to 12 in. Run-off and evaporation disposed of most of the water, restoring, in time, the former hard, dry condition. These alternate conditions of high and low moisture content, resulted in a considerable change in volume as was evidenced by the cracks formed in the drying out process. These "sun cracks" varied in width and depth, depending on the penetration of the surface water and on climatic conditions. Cracks, 1 in. wide and 8 in. deep, dividing the surface into numerous small polygons, were not uncommon.

It would appear, therefore, that little percolation, if any, takes place and that the ground-water level is not influenced by surface water. However, after a rainy period, a trench only 3 ft. deep shows seepage, whereas, in dry periods, 5 or 6 ft. may be excavated before ground-water is encountered. The water content of the soil, then, is affected to considerable depths by rain and melting snow and ice.

Behavior of Piles.—Two influences operate to make the soil unstable, the moisture which softens the surface layer and the plasticity of the under layers. For all building construction in the Port Newark area, pile foundations are required.

To attain a bearing value of 16 tons, it has been found that the average pile must be driven to about 18 ft. below mean low water. However, a wide range from this average is experienced. Numerous pile-driving tests have been made, but thus far no method has been found to predict the pile lengths required for the sites within the area. The minimum penetration may be to 12 ft. below mean low water in one place, while not more than 20 ft. distant, a maximum depth of 32 ft. will be necessary to reach solid bearing. Pile-bearing value is largely dependent on skin friction, yet from the road builders' standpoint these values suggest that the strata beneath vary to such an extent in thickness, moisture content, and physical composition, that they influence the surface stability even for light loading.

Results of Bearing Tests.—In an endeavor to determine just what reliance could be placed on the light load-carrying capacity of the soil, two bearing tests were made. These consisted in preparing a shallow excavation with a level bottom upon which several layers of railroad ties were laid, imposing an equally distributed load over 17 sq. ft.

Elevations were taken, as the initial loading was applied, at each of the four corners of the platform. A week later the load was almost doubled, and

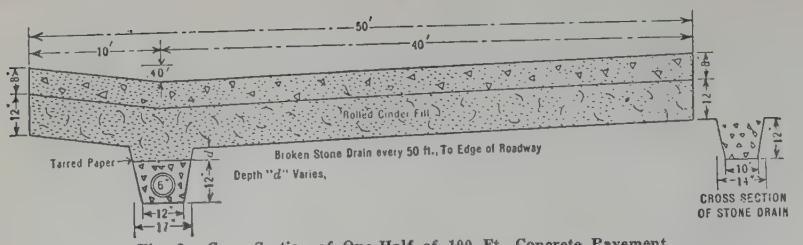

Fig. 2.—Cross-Section of One-Half of 100 Ft. Concrete Pavement

for a period of three weeks, observations were made to determine the settlement. In brief, the results of one test showed that a load of 174 lb. per sq. ft. caused an immediate net settlement of 0.008 ft. at the center; but despite the care taken to apply and distribute the loading equally, one edge of the platform had been raised and the other lowered.

After continuing to add to the load until 352 lb. per sq. ft. had been reached, the total settlement at the center amounted to 0.039 ft. When a week later a loading of 652 lb. per sq. ft. was reached, the settlement had become 0.172 ft. Without the application of further loading the platform settled progressively until at the expiration of the test period, of four weeks, a total settlement of 0.185 was noted. Meanwhile, the behavior of the corners demonstrated that even over 17 sq. ft. inequalities in soil-supporting power existed. In part, this was caused by the effect of moisture in softening the soil under the platform. During the test period, 2.14 in. of rain fell, the times of the heaviest precipitations being marked by the irregular settlement of the corners.

Soil Movements.—The movement of the top few inches of the clay, merely indicated by this test, was conclusively shown when cuts were made through a 3-ft. cinder railroad embankment placed on the clay fill. The clay surface under the center line of the track was depressed 6 to 18 in. and under the edges of the ties, 4 to 8 in., while outside the toes of the slopes it was forced upward 4 to 8 in. The extent of this movement was cumulative; that is, the deeper the clay depression became, the greater the volume of surface water collected and the more penetrating the moisture. Using the field test methods advocated by A. C. Rose,* Assoc. M. Am. Soc. C. E., the moisture equivalent of the subsoil was found to average about 50 per cent and the linear shrinkage, 7 per cent.

The influence of each of the two plastic layers just beneath the fill, was distinct. The meadow strata are very elastic and act as a cushion upon which the clay fill rests. Application of a light load to a sample of this spongy material results in considerable compression and a release of pressure causes almost complete restoration of volume. Filling over this layer compresses it as much as 5 ft. in places and slight additional settlement may occur for several years. The mud and silt layer, being in a semi-fluid condition, tends to flow in the direction of least resistance. The effect of this layer is to equalize pressures imposed on it. On a large visible scale this equalization occurred during the placing of the hydraulic fill. As the material rose in back of the bulkhead, acres of bay bottom, for ¼ mile, or more, seaward (formerly 2 and 3 ft. under water), emerged. This influence on surface structures cannot be disregarded, particularly when they are adjacent to the ship channel or bay front where the mud and silt layer is less confined. Imposition or removal of heavy concentrated ground loading, or the variable water loading due to tides, may operate, through this semi-fluid layer, to set up stresses in the clay crust.

Conclusions for Sub-Grade Study.—The foregoing studies and observations revealed so many indeterminate factors that a positive design, based on the usual assumptions, seemed impossible. The principal sub-grade factors that influence a pavement may be analyzed, however, and listed according to cause, effect, and remedy, as follows:

I.—Presence of Moisture in Clay Subsoil:
- (*A*) Cause:
  - 1.—Physical properties inherent in soil, such as,
    - (*a*) High moisture equivalent; and
    - (*b*) Finely divided condition.
  - 2.—Capillarity plus low elevation above sea level.
  - 3.—Long standing surface water, due to,
    - (*a*) Impermeability of soil; and,
    - (*b*) Irregular contour of surface.
  - 4.—Uniform strata of clay unbroken by veins or by adjoining strata of more permeable material.
- (*B*) Effect:
  - 1.—Lessened, variable, and uncertain bearing power due to plasticity.
  - 2.—Changes of volume due to excessive shrinkage.
  - 3.—Frost action.
  - 4.—Lateral movement of the topsoil on application of the loading.
- (*C*) Remedy:
  - 1.—Draining off the surface water.
  - 2.—Use of layer of fine granular material to:
    - (*a*) Decrease the height of capillary moisture;
    - (*b*) Quickly remove water from surface; and,
    - (*c*) "Cushion" the effect of frost "heaving."
  - 3.—Distribution of the loading over large areas.

II.—Movement of Sub-Grade Soil Layers:
- (*A*) Cause:
  - 1.—Additional compression of the meadow layer due to the added loading.
  - 2.—Further consolidation of the clay fill.
  - 3.—Equalization of pressures due to,
    - (*a*) Weight of tidal prism;
    - (*b*) Variation in the loading and of the surface.
    - (*c*) Deep excavations into the mud and silt layers.
  - 4.—Inequalities in the thickness of the layers.
- (*B*) Effect:
  - 1.—Permanent settlement.
  - 2.—Variable vertical movements.
  - 3.—Upheaval of the clay crust at planes of weakness.
- (*C*) Remedy:
  - 1.—Pile foundation for the pavement.
  - 2.—Use of substantial large sized paving units which would remain intact and keep their "riding qualities" while undergoing displacement due to subgrade movements.

Lessons From Existing Pavement.—In 1925 the construction and maintenance of roads and streets at Port Newark was transferred from the Bureau of Docks to the Bureau of Streets. At this time the only street in the south side area was a 36-ft. granite block pavement, 1,400 ft. long, laid in the spring of 1924.

This roadway consisted of 4 by 5 by 10-in. blocks laid on a 1-in. sand-cement cushion with joints of asphalt and sand, all on a 6-in., reinforced, 1:2.5:5, Portland cement foundation. Naturally, before the design and construction of additional streets, considerable study was given this one.

The base was reinforced with ⅝-in., deformed, square rods, on 6-in. centers transversely and 20-in. centers longitudinally, placed 2 in. above the bottom of the concrete. The pavement was laid on a 0.33 per cent grade and to a 4-in. crown, with one edge on the center line of the proposed 72-ft. width, the curb being about level with the surrounding ground. A depth of about 12 in. was excavated to provide for a layer of steam cinders. No particular grading or shaping of the clay under-grade was attempted, the spring rains creating a

*Proceedings, Am. Soc. C. E., January, 1928, Papers and Discussions, pp. 125 and 132.

deep layer of mud upon which cinders were placed and compacted as rapidly as excavation progressed. The result was a layer of cinders, 6 to 18 in. deep, spread and compacted over an irregular clay surface. No under-drains were placed.

Considering the subsoil drainage feature only, complete neutralization of the poor sub-grade was not accomplished. While it has been quite recently stated that "a poor sub-grade material can be transferred into a good sub-grade by the addition of sufficiently fine granular material or by the use of a layer of suitable granular material,"† this alone does not appear to effect the desired transformation at Port Newark.

It is true, the cinder course permits rapid percolation, keeps capillary water low, and acts as a cushion between the pavement and the volumetric and frost movements of the sub-grade; yet its efficiency is partly destroyed by the irregular contour of the under-base. Thus, when the clay sub-grade is recessed for the pavement, water will graitate to this trench and remain there, giving rise to lateral soil movement as found beneath the 3-ft. railroad cinder embankment previously mentioned. Irregularities of the clay, forming water-pockets, will aggravate the condition. Where a sufficient area is thus weakened beyond the ability of the concrete base to sustain the surface loading, failure might be expected. Examination of the pavement indicates that this may have occurred. The surface has many crosswise waves, the close spacing of the transverse reinforcing rods having doubtlessly prevented even more serious dish-shaped depressions. A more happy choice of reinforcing bar design might have still further aided in resisting the sub-grade forces.

As bearing out the assertion that sub-grade movements affect a pavement (equalization of pressure and other causes being ascribed), a comparison of elevations taken immediately after paving with similar readings taken in 1925, shows that, in general, a settlement (as much as 12 in. in some places) has occurred. A short section revealing a slight rise along one side and the irregular settlement over sections (as distinguished from localized areas), indicates the variable effect of sub-grade movements.

The relation between the location of such pavement movements and the many warehouses and other surface loadings has not been investigated. The fact that all buildings were erected subsequent to paving is, however, a starting point for such an investigation.

Under-Drains and Their Effect.—In the spring of 1926, when paving became necessary, the same conditions as existed for the 1924 paving were present, namely, a saturated top surface of clay, and standing surface water due to frequent rains. Two types of under-drains were used—a single arterial line in the center with laterals, for pavements of less than 50 ft. in width (Fig. 1); and a double arterial line, one under each gutter, with laterals, for pavements of greater width (Fig. 2). The arterial lines are 6-in. tile-drains (none extends more than 400 ft. before

Fig. 3.—Analysis of Reinforced Concrete Longitudinal Pavement Section

entering a surface-water catch-basin or open ditch) laid to a 0.50 per cent minimum grade, recessed in the clay under-grade, and completely surrounded by broken stone. Tees are placed every 50 ft. from which broken-stone drains through the clay run out to the edge of the pavement. Tarred paper around joints, between the cinders and the broken stone, and other features common to such construction were included. In addition to the tile and stone drains, the clay under-grade was carefully shaped to direct water toward the arterial drains.

The value of these under-drains first showed itself when a dry clay under-grade was obtained upon which a layer of cinders could be carefully laid and compacted in place. After a pavement is laid their value is, of course, not so apparent. In view of the paradoxical results as to moisture content obtained under drained and under-drained sections of the Bates Test Road,‡ it might appear that tile drains fail to live up to expectations. The common assumption is that a tile pipe will drain a width of about six times its depth in clay soils, and fifteen to twenty times its depth in porous soils. When this assumption is made the fact that "time" is an important element is generally overlooked — particularly where clay soils are concerned; for, if drainage becomes operative only on saturation of the clay, then its value is nil. On the other hand, if a rate of flow through the soil is established shortly after the surface is wetted, then the system has merit.

Field studies would best determine the behavior of water on passage through a clay subsoil. However, as an index to what may occur, the experience of the writer in making the moisture equivalent tests will serve. Samples of the subsoil were gathered. While obviously the clay contained moisture, the masses were hard to break up and no dampness was visible; not even did the paper on which the samples were laid, become moistened. So little water was added to produce a "shiny" surface on the test samples of the clay that the writer decided to dry out the unused portions of several samples and thus, by weight, determine what moisture was originally present. The results showed that each sample in its original state contained about 20 per cent of water. If a mass of 25 lb. of such clay can be removed from the ground and exposed without drying out, it is evident that the most closely spaced tile drains will likewise fail to remove the moisture. While from the appearance of the clay this condition did not affect its bearing power, yet, evidenly, much more moisture would accumulate before "seepage" or drainage would begin.

Assuming, then, that the tile and stone drains are ineffective in themselves in draining water through clay, they still are important in removing the water brought to them by the sloping clay under-surface. To recapitulate:

1.—The porous cinder layer rapidly removes water from beneath the pavement;

2.—This is added by the herring-bone under-drainage system; and

3.—Water otherwise saturating the clay to disintegration is drained, as surface water, into the "broken-stone gutters."

Concrete Pavement Provided.—Consideration of various types of pavement finally led to the selection of concrete as best suited to the sub-grade conditions at Port Newark. The developed design consists of a 1:1.5:3 portland cement, reinforced, concrete pavement laid to a uniform thickness of 8 in. The double mat reinforcement is composed of ⅝-in. deformed round bars assembled so that the lower mat is supported 2 in. above the bottom of the pavement and the upper mat is separated therefrom by 3½ in. The lower members are spaced 8 in., both transversely and longitudinally; the upper transverse bars are on 8-in. centers, while the longitudinal bars are on 16-in. centers. The reinforcement extends to within 2 to 6 in. from the edges of the slabs, adjacent mats being properly lapped and the other usual practices observed.

All joints are vertical, with ¾-in. dowel-pins connecting the slabs across transverse joints. At all slab corners and angles, ⅝-in. bars, 6 ft. long, were bent outward in the form of a **U** (sides at an angle of 22 deg.) and placed in the top mat to combat corner failures. The specifications under which the work was performed, embody many of the proposals advanced by the committees on concrete pavement specifications of various technical societies. Daily laboratory tests checked the quality of the materials used and the strength of the resulting product. In

†"Recent Conclusions in Highway Research," by A. T. Goldbeck, Assoc. M. Am. Soc. C. E., Roads and Streets, March, 1925, p. 458.

‡"Tentative Conclusions on Design of Concrete Surfaces," by Clifford Older, M. Am. Soc. C. E., Roads and Streets, May, 1924.

the field, the slump test was used to control the consistency of the mix.

In scrutinizing any concrete pavement design, examination in the light of recent investigation is desirable. Each feature of this design will be so considered.

The 1:1.5:3 mix, with trap rock as the coarse aggregate, appears to represent the greatest strength and the least variability for road-building purposes. Accelerated wear tests conducted by the U. S. Bureau of Public Roads reveal that a 1:1.5 mortar with trap-rock aggregate provides one of the most resistant surfaces to abrasion.§ It is particularly fitting that this mix be used at Port Newark where heavy trucking is the principal class of traffic.

Students of recent development in design will be inclined, no doubt, to view a uniform thickness as a less advanced feature than the remainder of the design. It is usually assumed that a wheel load 3 ft. from the pavement's edge will do no damage. This being the condition at Port Newark, there is no reason for increasing the thickness of these pavements. Traffic is inclined to avoid the edge (on the 100-ft. streets) due to the depressed gutter lines, and likewise on the 48-ft. streets, due to the adjacent poles or other like features.

Recent studies¶ made public by the Highway Research Board of National Research Council, show that by increasing the reinforcement, a reduction in cracks is obtained more economically than by increasing the concrete thickness. Specifically, 170 lb. of bar reinforcement per 100 sq. ft. (50 per cent each way) causes a reduction in combined transverse and longitudinal cracks equal to an added 2-in. center thickness of concrete. In the design used at Port Newark there is 169 lb. of reinforcement symmetrically placed, the added alternate transverse bars in the upper mat making the total reinforcement 198 lb. per 100 sq. ft. It would follow, then, that the effectiveness of at least 2 in. of added concrete is obtained with respect to crack reduction.

Furthermore, the report states, for equal weights of reinforcement small bars closely spaced are more effective in minimizing crack development than larger bars. At Port Newark with ⅜-in. bars, 8 in. apart, it is hoped that a proper distribution has been achieved.

A pavement slab design cannot be analyzed with as great a degree of certainty as the usual floor-slab, yet there are reasons why the same kind of an analysis may be applied. It may be desirable, for example, in a comparative study, or in determining the capacity of the slab to bridge newly back-filled utility trenches; or as in the present case, in indicating the extent to which sub-grade failures will be harmless and in suggesting the possible piling required where total sub-grade failure is expected.

Computation of Strength. — Where only occasional sub-grade failures are expected, pavement slabs are not designed to carry their loads entirely unsupported since such a course would be both extravagant and unjustified. At Port Newark, localized areas of non-support might possibly occur due to partial disruption of the drainage system or minor settlements attendant on the movement of the underlying strata. When such areas do occur, the worst possible condition will not be 36-ft. slab supported at its ends only, since such a condition would pre-suppose exceptionally high bearing value for the sub-grade immediately adjacent to the "failure" and the ability of the dowel-pins to withstand the resulting shear. Instead, some indeterminate lesser area of non-support will generally develop, and then the slab, as a unit, will settle to a new bearing. Impact, inertia of the slab, and the many other factors, however, may operate to cause failure of the slab before it can adapt itself to the new plane of support.

As pavement slabs are used for years following their initial failure and as so many variable and uncertain elements preclude an accurate mathematical analysis, it is not so much the "safe" carrying capacity, but the ultimate carrying capacity, that is desired. For this purpose it is proposed to use 1,500 lb. per sq. in. as the "yield point"** of the 1:1.5:3 concrete; 40,000 lb. per sq. in. as the yield point of the steel; and $n = 12$.

Taking a longitudinal section of the slab, 8 in. wide, and analyzing it as a continuous beam by straight-line formulas,†† and neglecting for the present the upper mat (Fig. 3(a)):

a_s=0.1105 sq. in.
p=0.0023
k=0.2089
j=0.9304
kd=1.25 in.
jd=5.58 in.
M_s=24 643 in-lb.
f_c=880 lb. per sq. in.

An examination of Fig. 3 shows that the upper steel falls below the neutral plane.

Treating the entire steel system as taking the tensile stress in the beam at a depth equal to the distance of its effective center of gravity below the surface (Fig. 3 (b)), then

d=4.83
a_s=0.1658
p=0.00429
pn=0.05148
k=0.273
j=0.909
kd=1.32 in. (or 1.18 in. above the top steel).
jd=4.39 in.

$M_s = 27\,370$ in-lb. $= \frac{27\,370}{12}$ ft-lb.

f_c=1 260 lb. per sq. in.

Using $M = \frac{w l^2}{12}$ as for a continuous beam,

$$\frac{w l^2}{12} = \frac{27\,370}{12}$$

or,

$$w l^2 = 27\,370$$

Then, if, w=500 lb. per sq. ft.=333 lb. per running ft.,

$$l^2 = 82$$

or,

$$l = 9 \text{ ft.}$$

Thus, a load of 400 lb. per sq. ft. in addition to the weight of the slab may cause failure due to bending stresses, when the unsupported area has a width equal to that of the slab and a length of 9 ft. The analysis of a transverse section in a like manner will reveal a greater resistance to failure because of the additional steel in the top mat. A cursory examination shows that a concentrated wheel load of 7 tons will probably cause failure of the slab over an unsupported area the width of the slab and about 4 or 5 ft. long.

Where negative bending moments occur, the top steel should take the tensile stresses in the upper part of the slab. Failure under such a load will be perhaps more frequent (due to the position of the steel below the surface) than that caused by a positive moment.

When it is considered that the deflection of a slab under loading may add sub-grade support, and that with a smooth concrete surface, impact is kept at a minimum, the Port Newark slabs may be said to possess a relatively high resistance to failure—but should failure occur, a separation into rather large square sections will result, with the steel stressed beyond its yeild point, but still linking the sections together.

If a pile foundation is adopted to replace efforts at under-drainage, it will be necessary to re-design the slabs, decreasing the size and increasing the reinforcement in order to transfer the surface loading to the piles. Use of 6 by 7-ft. slabs, 8 in. deep, with about 270 lb. of steel per 100 sq. ft. and rows of 30-ft. piles, 8 to a "bent," with the bents 6 ft. apart, might be the principal elements of a possible design adopted. Whether the use of the Compressol System would be as suitable and more economical has not been investigated as yet by the Newark Bureau of Streets.

Comparison of Paving Costs.—Itemizing the approximate actual cost per square yard of both types of pavement and under-drainage laid at Port Newark, and estimating the probable cost of a pile-supported pavement, the results are as follows:

Granite Block (Actual Cost):	
Pavement on 6-in. concrete base (including 6 in. of excavation)	$ 7.38
Reinforcement (about 31 lb.)	1.40
Excavation (average)	0.70
Cinder fill (average)	0.90
Average cost per square yard	$10.38
Reinforced Concrete (Most Recent of the Three Contracts Let):	
Pavement complete	$ 3.57
Excavation (average)	0.84
Cinder fill (average)	1.60
Tile-drain (average)	0.20
Stone-drain (average)	0.40
Average cost per square yard	$ 6.61

§"Researches on the Structural Design of Highways, by the United States Bureau of Public Roads," by A. T. Goldbeck, Assoc. M. Am. Soc. C. E., Transactions, Am. Soc. C. E. Vol. 88 (1925), p. 264.

¶Report, Highway Research Board, National Research Council, Vol. II, 1926, p. 12.

**See Bulletin No. 5, Structural Materials Research Laboratory, Lewis Inst., Chicago, Ill.

††Symbols and analysis follow the Report of the Joint Committee on Standard Specifications for Concrete and Reinforced Concrete, Proceedings, Am. Soc. C. E., October, 1924, Papers and Discussions, p, 1153.

Pile-Supported Pavement (Estimated Cost):	
Pavement slab	$ 4.50
Pile foundation	7.00
Cinder fill	1.60
Excavation	0.80
Average cost per square yard	$13.90

Leaving aside the cost of surface drainage, gutter curbing, etc., the reinforced concrete pavement used at Port Newark appears to be the more economical in comparison with the granite block, and the more likely to prove satisfactory. Should it prove to deteriorate rapidly, the more than twice as expensive pile-supported pavement may receive serious consideration as a substitute.

Results to Date.—As the pavement is of comparatively recent construction, no time-proven conclusions as to its effectiveness can be drawn. However, interesting observations have been made.

Sub-grade movement has occured and displaced the pavement, noticeably, at three locations. In all cases it is at slab junctions and has in no wise affected the integrity of the slabs. At the maximum depression, water 4 in. deep is pocketed. Since numerous track crossings prevented the adoption of steeper grades, relatively slight slab settlement causes these water pockets to form.

Examination of the tile-drain outlets during rains shows them to be carrying a considerable volume of water during and after such periods. What settlement has occured is believed to be due to the major movements of the under-grade layers and not to movements arising from moisture-laden subsoil. Check elevations recently taken over the pavement substantiates this belief in revealing, over considerable areas, elevations differing from those to which the concrete was originally laid. The ability of the slabs to withstand displacement of this character or adopt themselves to it, while under traffic, seems, thus far, to justify the design used.

Conclusion.—At present, considerable study is being given to subsoil problems. As heretofore, the actual service experiences will apply the final test to the various solutions advanced and will point the way to still further improvements. Where a more or less experimental or novel design is used, it is believed an account of the surrounding circumstances will be of interest to engineers confronted with similar subgrade conditions. No claim is made that the Port Newark pavement is the best design possible nor that it is entirely original, since the experience of others in the highway construction field has been freely drawn upon; but it is one in which the City of Newark reposed sufficient confidence to expand $148,000.

Hydraulic Gradient

Its Use in Water Works Maintenance

By ELMER G. HOOPER
Associate Professor of Hydraulic Engineering, New York University

THE hydraulic gradient is a most useful and singularly successful means for solving certain kinds of problems that come up in maintenance, but it is necessary to recognize its limitations in order to retain full confidence in it. I shall try to demonstrate by example later on in this paper the type of problem that may be readily handled and show how in one or two cases the method had to be supplemented by other means to complete the solution. First, however, I will ask you to bear with me while I go into hydraulic theory a little and try to interpret it in a way that is useful to the practicing water works man. Some of you may be bored because I am telling you something you already know, but I am sure there are others who have forgotten enough of it to make it worth while to refresh your memories.

The Hydraulic Gradient Theory.—The "Hydraulic Gradient" may be defined as a continuous line or connected series of lines following the horizontal meanderings of the pipe or conduit but at a distance above or below it equal to the height to which the water from it would rise due to pressure in the main, either positive or negative. In other words it represents the limit of height to which water from the main could be delivered at any point. A sloping gradient indicates flow; a sudden drop in a sloping gradient at any point indicates concentrated loss of head, as at a partially closed gate, an obstruction, or a change in diameter of pipe section if the gradient has a different slope following the drop. A gradient changing suddenly from a steep slope to a less slope without change of pipe diameter usually means a large concentrated outflow at the point of gradient change, though it may mean a flow from a very old pipe into a new pipe of the same diameter. A horizontal gradient indicates no flow or very little; when a flat gradient drops suddenly at a point and resumes beyond at a lower level it indicates a disconnection, a gate down or a complete obstruction. In all these the point at which the gradient breaks is the important one. A gradient that slopes too steeply indicates too much flow for that size of pipe or too much deterioration in the pipe to permit that flow; in any case a gradient that is found to be much steeper than it normally is usually means excessive draft, probably leakage.

The mathematical expression for the hydraulic gradient may be obtained by transposing Bernoulli's Theorem, which must be familiar to all who have studied hydraulics in recent years. The theorem may be written in the following form between any two sections of the main:

$$\frac{v_1^2}{2g}+\frac{p_1}{w}+z_1+h=\frac{v_2^2}{2g}+\frac{p_2}{w}+z_2+L.H.$$

where v represents velocity at the respective sections,
p represents gauge pressure if w is 0.434,
z represents elevation of the pipe at the respective sections,
h represents lift from pump if there is one between the sections,
$L.H.$ represents the sum of all losses of head between the sections,

and $\frac{v^2}{2g}$ is the height in feet to which the water would rise due to velocity alone; $\frac{p}{w}$ is the height to which the water would rise due to pressure alone if an open vertical tube were inserted in the pipe (the height of the gradient above the pipe at the point); z is the height of the section of pipe above a common datun; the losses of head are divided for convenience into those due to friction in pipe of uniform diameter, to bends, to expansions and to contractions of sections, and then summed up. If a common level or datun is used it may be seen that the term $(\frac{p}{w}+z)$ is the height of the gradient at the section above that common level, and that $(\frac{p_1}{w}+z_1)-(\frac{p_2}{w}+z_2)$ is the drop of the gradient betwen the two sections. If we transpose Bernoulli's equation to produce this form we will have the following:

$$\left(\frac{p_1}{w}+z_1\right)-\left(\frac{p_2}{w}+z_2\right)=\frac{v_2^2}{2g}-\frac{v_1^2}{2g}+L.H.-h$$

meaning that the gradient drops due to loss of head, rises due to lift of the pump, drops if the velocity increases and rises if the velocity decreases. For practical water works purposes outside the pumping station all items except loss of head may be neglected and we may say then that the drop in the gradient is from loss of head. The drop in the gradient is therefore a measure of the efficiency of the parts of the system, and the nature and magnitude of the drop may be interpreted to tell whether anything is wrong, and may indicate what and where.

Application of the Gradient to Practice.—To illustrate the application of the gradient to practice, I am drawing on my memory of experiences in the service of the Department of Water Supply, Gas and Electricity, New York City, and because of the ten years or more that have elapsed since that service only a few outstanding examples are clear enough in my mind to

present them. As the cases are described you will no doubt say to yourselves, "why, he is only taking pressures." I shall fully agree with you, for it is the pressure reading converted to feet head and added to the hydrant elevation that gives the gradient elevation. You will appreciate then that it is only a common, everyday job that can be put to very useful ends when properly interpreted.

Case 1: An abnormally steep gradient, indicating excessive flow on a 12-in. main in 43rd St., Manhattan, between 5th and Madison Ave. A casual pressure taken on a hydrant on the north side of 43rd St., east of Madison Ave. seemed to be much lower than the district should have and this was verified as fact by pressures taken on mains in the same service not closely connected to the one suspected. This latter main had no connections to any other mains at or near Madison Ave. and 43rd St., though had there been any they would have been closed temporarily to permit flow from the two ends only, for the purpose of the investigation. The problem then consisted in determining and analyzing the gradient on a line 12 in. in diameter beginning at a 20-in. trunk main in Fifth Ave., extending east through 43rd St. across Madison Ave., where it changes to 6 in. in diameter continuing east to Vanderbilt Ave. at Grand Central Terminal, then north one block to 44th St. in which it turned west to connect with a 12-in. main in Madison Ave. There is a valve in 43rd St. east of Madison Ave. but west of the hydrant on which the first pressure was taken. This valve, a 12-in., will be designated as valve 1 for future reference. Valve 2, a 6-in., is on 44th St. east of Madison Ave. There were five hydrants on the line at which pressures were taken and converted to feet head. Elevations of these hydrants were determined by hand level readings from the most convenient street intersection whose elevation was known or could be assumed for datum, and the spacing of the hydrants was measured by pacing. By adding the pressure head to the elevation for each hydrant and plotting it to scale for the whole line a gradient was found consisting of two sections, each having a fairly steep slope downward from the ends of the main toward a common point about on the east building line of Madison Ave. and 43d St., near valve 1. In order to find on which side of this valve the outflow occurred, it was closed so that the supply could come from only one direction. The hydrant pressure dropped to less than zero, showing that the flow was from the east through the 6-in. line to a point just east of the valve, and that the amount of outflow was equal to the capacity of that line at least. For checking the location of the outflow and to obtain data to compute the amount, valve 1 was opened and 2 was closed and simultaneous pressures were taken for a new gradient.

Investigation showed that Grand Central Terminal improvements extended under the block from Vanderbilt to Madison Ave. east building line; that the main dropped several feet to pass between the floor of the basement and the ceiling of the sub-basement; that a 6-in. blow-off had been installed and connected with the sewer at that level in the west wall of the basement; that a special operating wrench for the blow-off gate had had to be provided; and that finally this gate was wide open thereby filling the sewer, a large one, more than two-thirds full. It was estimated from the pipe size and loss of head that about 4 m.g.d. was wasted and the sewer marks indicated it had been doing so a long time.

Another example quite similar to the above, except that it was on a submarine line, was taken as the subject of a brief paper read before a meeting of the New England Water Works Association in 1916.

Case 2: Gradient slightly lower than normal on a trunk main where pressure variation was usually slight; pressure reading was only about a pound lower than normal on a hydrant from a 20-in. main a few hundred feet east of its connection with a 48-in. main. This was on Pelham Parkway east of Southern Boulevard, the Bronx, on a main leading about 6 miles to City Island, having two 12-in. and one 8-in. lines at intermediate points normally feeding out toward Westchester village. When the gate was closed on first 12-in. feeder the gradient showed that the flow had been into the 20-in. main; the same thing was indicated at the other two lines showing a heavy draft toward City Island. At two points the 20-in. line divided into two 12-in. lines for under water crossings and the closing of these in succession affected the gradient in such a way as to show the supposed trouble to be still farther ahead and the gradient was becoming noticeably lower and lower. The heavy flow was finally pinned down to an 8-in. under water line about a mile long, which together with a 12-in. line supplied Hart's Island with water. When this crossing was shut off the local pressures went up from about 25 to over 40 lb. The slope of the gradient was used to determine the approximate location of the leak and by using a boat, which acted as a good aquaphone, the location was checked and buoyed for the repair crew. This leak or series of leaks (three lengths of split pipe not far from each other) was under 16 ft. of water at low tide. Less than a day was consumed from the time the suspicion was first aroused until the trouble was located, and for the most part by hydraulic gradient.

Case 3: Flat gradient followed by sudden drop. On one of the early days of 1917 when troops were being assembled and trained at Fort Schuyler, N. Y., water was suddenly cut off from the post. After considerable delay and late in the day word of the trouble was received. From the story of those on the ground the easiest and most obvious thing to produce results seemed to be pressure readings on hydrants outside the reservation since it was known there was no pressure within. The first reading taken showed a pressure slightly above normal, indicating at once a plugging of the line. Further investigation discovered a 6-in. meter with a strainer just inside the reservation and a very large eel tightly squeezed into the strainer thereby shutting off the entire supply. The trouble was located in about a half hour and remedied in another hour.

Another somewhat similar procedure discovered a rather unique plug in a section of 6-in. water line at 140th St. and East River which connects with an under water line to North Brother's Island. About 50 ft. of fire hose without couplings and tightly folded into the pipe by unbalanced pressure, produced by its own resistance to movement, completely shut off the supply of water to the island from the Bronx mainland, leaving the island dependent on another submarine line to Riker's Island and the mainland beyond. This was discovered when investigating the adequacy of fire protection for the island. The reason for the hose being in the pipe was learned later, but it would take too long to tell it here.

Under this case also would come the examples of gates closed and of pipes cut and capped. Such conditions were met with a number of times and it was not possible in any of the cases to tell which of the two were responsible until an excavation and an examination had been made. Because this was not an unusual or startling condition no particular one stands out in mind sufficiently clearly to be reproduced.

In the preceding paragraphs enough of both theory and of practice has been presented to provide food for reflection and it is to be hoped that some new and workable ideas have been suggested to some of you who have had the patience and the kindness to listen.

Acknowledgment.—The above is an abstract of a paper presented May 3 before the New York Section of the American Water Works Association.

Methods of Thawing Frozen Hydrants

According to a study of the methods used for thawing out frozen hydrants made by the New York State Bureau of Municipal Information, 25 municipalities use steam for this purpose, ten use electricity, seven use a commercial hydrant-thawing device, and five use salt, carbide or other materials. Two municipalities use alcohol in the hydrants to prevent freezing, and fourteen reported that they never experienced any difficulty with the freezing of hydrants.

Removal of Iron From Hard Ground Waters

Occurrence, Effects and Methods and Costs of Treatment

By R. L. McNAMEE

Principal Assistant Engineer, Hoad, Decker, Shoecraft and Drury, Ann Arbor, Mich.

IRON is found in solution in the ground waters of glaciated regions of the Middle West as ferrous carbonate. The soils contain iron as the ferric oxide (Fe_2O_3). Ground waters, especially in deeper strata, reduce the iron to the ferrous oxide (FeO). Carbon dioxide, common in hard waters, combines with the oxide to form ferrous carbonate. The ferrous carbonate is relatively stable under conditions such that the carbon dioxide is held in solution and oxidation does not take place. But when these conditions are not maintained and the water is exposed to the air as in open reservoirs or when drawn for use, a natural oxidation takes place and the iron reverts to an insoluble state and settles out or deposits upon many surfaces with which the water comes in contact.

Effect of Iron in Water.—The objectionable qualities of iron-bearing waters are common knowledge in Indiana. Plumbing fixtures become stained a reddish brown color where water drips from faucets. Fabrics acquire a yellowish discoloration in the laundering process. Certain industries find it necessary to eliminate the iron before using it. Under some conditions, dyes cannot be applied with waters having iron in solution. Woolens in the process of fabrication are discolored in washing. In the kitchen, also, iron has undesirable effects. Under some conditions it is impossible to brew tea of satisfactory taste. Certain vegetables assume disagreeable flavors when cooked in iron-bearing waters. When the Crenothrix is present, unpleasant tastes and odors are often present in the tap water.

These conditions, or some of them, are noticeable generally when the iron content exceeds 0.5 p.p.m. The United States Treasury Department Standard for drinking waters for use on common carriers in interstate traffic provides that the iron should not exceed 0.3 p.p.m.

Method of Treatment.—The artificial means of treatment employed to remove iron are substantially the same in principle as those natural processes which cause the precipitation and deposition of iron at the point of use. The treatment generally consists of three processes in series: aeration, sedimentation and filtration. Under certain conditions treatment with a coagulant is necessary in order to secure effective sedimentation. The aeration is the means by which the iron is chemically changed from the soluble to the insoluble form. The sedimentation is the means by which part of this insoluble iron is separated from the water. Some of it is in such a finely divided state that it will not settle within reasonable length of time, for which sedimentation basins may be provided. Filtration through sand is utilized to remove these finer sediments, for which purpose it has come to be an essential element of the treatment.

The removal of iron is not always so simple as this statement of procedure may indicate. The problem varies with the chemical content of the water and is seriously complicated with waters high in organic matter or bearing manganese in considerable amount.

Aeration.—The aeration of water is usually accomplished by the exposure of the water to the atmosphere under conditions favorable for its absorption. In a few instances, aeration has been provided by forcing air through the water by means of grids of perforated pipes or diffusers placed at the bottom of tanks through which the water passes. Aeration by such means is provided, incidentally, by the air lift pump, for which purpose this type of pumping equipment is to be preferred for iron bearing ground waters in some cases, over other types. Of all its applications the air lift pump is, of course, best suited to raising water from wells.

A variety of devices have been developed and are being used to facilitate the exposure of water to the atmosphere for purposes of aeration. Essentially they may be classed in three groups: sprays, falls, and contact trays. In many plants, a combination of two or more devices is employed.

Sprays are of several types, from simple orifices in pipes to more complicated whirling nozzles similar to those used for lawn sprinkling. An unique and efficient spray nozzle is that developed for use at the Sacramento water purification plant. The nozzle proper is formed as a bell-mouth facing upward. The throttling is secured by means of a conical casting which is floated by the head of water and which deflects the stream into a thin sheet over a wide radius. It operates well under considerable variations of head.

Sprays of one type or another are employed for aeration at Amesbury, Mass., Griffin, Ga., Lawrence, Kan., Leroy, O., Long Beach, N. Y., Middleboro, Mass., Selma, Ala., Stuart, Fla., and Wadsworth, O. The plant now under construction at LaPorte, Ind., will use sprays of the Sacramento type.

Falls in their simplest form consist of riffles, sloping surfaces sometimes provided with low baffles or ridges, over which the water flows in a thin sheet and thus exposes a large surface to the air. This type has the advantage of a low head loss but requires a comparatively large area. Some plants use a series of steps so arranged that the water has a free fall of about a foot between steps. This type requires more head than the riffles, but less area and in general will effect better aeration due possibly to the splashing of falls on the succeeding steps. Multiple splash trays are an elaboration of the series of steps. They consist of a number of shallow pans so arranged at levels one below another that the water overflowing the rims of pans on one level is caught on the pans of the next level below. This type secures the benefits of both the thin sheet of the riffles and the free fall and splash of the steps and is more economical of area than either.

Falls of one type or another are employed for aeration at Champaign, Ill., Excelsior Springs, Mo., Garretsville, O., Liberty, Mo., Red Bank, N. J., Sioux Falls, S. D., and Superior, Wis.

Contact trays are commonly built as a series of trays mounted one above another and filled with coke to depths ranging from 3 to 12 in. The water is piped to the uppermost tray and then trickles downward through the coke and drops through slots or perforated openings in the supporting tray to the next lower one. They accomplish aeration by causing the water to spread out over the surface of the material and absorb air which may freely pass through the shallow depth of material.

Contact trays are employed for aera-

tion at Liberty, Mo., Lodi, O., Memphis, Tenn., Shelby, O., Wausau, Wis., and Xenia, O.

Coagulation.—In certain cases, the iron, after aeration, seems to exist to a large degree in an extremely finely divided or colloidal state, such that it is very difficult to settle. In such cases, the sedimentation is materially improved by treating the water with some form of coagulant. The agents ordinarily used for this purpose are lime, which also serves to remove the carbon dioxide, or a finely divided clay which seems to benefit sedimentation by a sort of mechanical coagulation. Ordinarily in the middle western states the iron precipitates readily following simple aeration, so that the use of a coagulant is not necessary. The treatment of the water with lime is sometimes used, however, for the removal of carbon dioxide.

Sedimentation.—The separation of a large part of the insoluble iron carbonate resulting from the process of aeration is ordinarily practicable by allowing the water to flow slowly and quietly through basins of ample capacity. In waters containing much organic matter the use of a coagulant is necessary. A detention period of about six hours is usually sufficient to settle out the bulk of the iron sludge. The amount that will not precipitate within this length of time can be more economically removed by filtration.

When used following contact beds, sedimentation performs an important service in catching and settling out the sludge which occasionally sloughs off from the contact medium.

Filtration.—The process of filtration as applied for the removal of iron provides means for the deposition of the insoluble iron upon the surfaces so arranged that they may be cleaned at intervals as necessary. Two principal forms have been employed, contact beds and sand filters.

Contact beds are intended to supply a large surface area over which the water passes and upon which it deposits the insoluble iron particles. Where sufficient aeration is otherwise provided, these beds are not primarily designed to aerate the water. Under some conditions, they are operated submerged with water, a condition that precludes aeration from the atmosphere. In various plants, they serve both functions of aeration and deposition by contact in various relative degrees.

A variety of designs have resulted from the various uses of contact beds. The flow may be either downward or upward. The downward flow bed provides opportunity for aeration, controlled by partial submergence if desired. Upward flow beds must always operate submerged. The contact medium is usually coke but a great variety of materials such as shavings, wooden slats, bricks, and broken stone have been used with success. Provision must be made for flushing out the accumulated iron deposits at intervals. With some contact media, a positive washing arrangement must be provided.

The use of contact beds as a final treatment process is not always satisfactory. With high initial iron content the amount removed is usually high, but this process may leave too great an amount remaining in the effluent. In such cases, they are commonly operated as prefilters, followed by sedimentation and sand filters.

Contact beds are used at Amesbury, Mass., Brookline, Mass., Griffin, Ga., Leroy, O., Lowell, Mass., and Middleboro, Mass.

Sand filters, insofar as their service for the removal of iron is concerned, are simple strainers exposing large contact surfaces to the water. For such purposes alone, they usually remove iron more thoroughly than contact beds. But, in addition to the service in iron removal, the filtration process yields such important benefits in clarification and bacterial removal, that its use is warranted even at the somewhat greater first cost. Sand filters are more easily controlled and less subject to periods of inefficient operation than the contact beds. In general, the design of filters for iron removal is not greatly different from those for other purposes of water purification.

Plants of the following places employ rapid sand filters as a final iron removal process: Benton Harbor, Mich., Champaign, Ill., Freeport, Ill., Griffin, Ga., Iowa City, Ia., Leroy, O., Marshalltown, Ia., Memphis, Tenn., Red Bank, N. J., Selma, Ala., Shelby, O., Sioux Falls, S. D., Wadsworth, O., Wausau, Wis. The plant now under construction at LaPorte, Ind., will use rapid sand filters.

Efficiency of Iron Removal Plants.—A number of iron removal plants in the middle western states treating water generally similar to that from the ground water sources of Indiana are shown in Table I. The treatment processes employed are indicated and the iron content of both the raw water and final effluent is stated as reported by designing engineers or plant operators.

These data indicate that modern well-designed plants employing aeration, sedimentation or prefiltration and final filtration will reduce the iron naturally present in ground waters to amounts that cause no objection. Some of the data given resulted from experimental studies or early operation periods of new plants and it is probable that even better results have been obtained with these plants after they have become well regulated.

Cost of Iron Removal.—It is not possible to determine easily either the average investment cost or the average operating cost of iron removal plants. Variable conditions materially affect the design of plants and the cost of their construction. In many cases, existing works are utilized with considerable saving in new investment.

Table II gives a general idea of the investment usually required for iron removal plants. The data are as reported in current literature. Full details of the structures and equipment covered by these are not stated in all cases.

In all of these plants the filtration is provided by rapid sand filters of modern design which, in addition to their functions in the removal of iron, also clarify the water and eliminate bacterial pollution.

The data indicate that complete iron removal plants, employing the processes of aeration, sedimentation and filtration, and chemical treatment if necessary, will cost from $35,000 to $45,000 per million gallons per day of nominal capacity. Substantial reductions from these figures may often be secured where it is possible to utilize existing basins and structures to advantage.

Acknowledgment.—The above is an abstract of a paper presented at the 1929 convention of the Indiana Section of the American Water Works Association.

Protection of Water Supply Catchment Area

An Interesting Discussion of the Control of Watersheds

By JOHN F. SKINNER
Sanitary Engineer, City of Rochester, N. Y.

OUR first thought in connection with a watershed should be "conservation." We must conserve the water which it produces both as to quantity and quality. To do this we should preserve natural conditions, forest conditions and soil conditions, cleanliness and sanitary conditions, and also beauty and public opinion for if we are careful not to mar the landscape and not to make a point of excluding those who may enjoy its recreational aspects we shall go far toward securing cooperation in maintaining the cleanliness which is so much to be desired. To this end the watershed may be made a sanctuary for wild life; unusual types and specimens of trees may be marked, as in a park; roads may be constructed to make the entire territory accessible and recreational features may be stressed or at least allowed under proper regulations.

Sources of Water Supply.—If the water supply is from wells, less attention will be paid to the catchment area. Artesian wells which pass through impervious rocks or clay materials may reach water bearing sands which derive their water from distant sources and the water will be naturally filtered. Wells into limestone which receive through large fissures are often polluted. A study of the geology of the region may disclose the origin of the water and in some cases protection of the catchment area may be valuable. Shallow wells sunk into water bearing sand or gravel require protection in the immediate vicinity of the wells and the water from a greater distance will be naturally filtered.

When a supply is taken from a large stream or lake it will generally be economically inexpedient to attempt to protect the watershed; attention may better be devoted to the location of the intake, to minimizing local pollution and to subsequent treatment of the water.

For surface supplies from sparsely inhibited upland areas, considerable attention may be paid to protective measures and if the property is cheap, large areas may be purchased and controlled. Where the storage is small so that chance contamination may reach the supply quickly, people should be excluded as thoroughly as possible from the watershed; if, on the other hand, there is long storage the public may be admitted under proper regulations and restrictions, and the portion of the area farthest from the intake or diversion may be opened to campers, tourists and fishermen.

If the area is flat agricultural land with gentle slopes toward the main stream or lake, it may be sufficient to acquire a marginal strip of 100 yards or less along the shore of the lake or reservoir. In addition to this, highways within this line should, in general, be relocated further back and outhouses, hog pens, barnyards and refuse dumps should be removed from the immediate banks of tributary streams and garbage should be collected and treated or buried so that it will not reach the streams. The territory acquired should be policed and notices should be posted along the nearest highways, particularly at stream crossings.

If the area consists of steep, rugged land from which the water runs off rapidly, particular attention should be paid to villages and dwellings, to prevent crude sewage from washing into the reservoir. Of course, on such land, there is apt to be the minimum of inhabitants and the land will generally be cheap and readily purchasable.

If land is highly cultivated, it will have a larger population of men and animals and consequently be more subject to contamination.

Mr. Paul S. Fox, in his paper "Watershed Sanitation," which appeared in the Journal of the A. W. W. A. (July, 1928, Vol. 20, p. 50) states that the New Mexico code empowers the governing body of a municipal corporation to exercise control over a watershed for a distance of 5 miles above the point of diversion. He also writes: "On the watershed grazing was prohibited, which seems to be next to impossible. It was reduced, however, to a minimum and the improvement from a bacteriological viewpoint was remarkable. The restriction of recreational uses under controlled conditions was effected by ordinances, posting and policing."

Villages.—Small settlements on the immediate shores of the reservoir should be purchased and removed wherever possible. More remote villages and those too large and expensive to destroy must receive especial attention. Their wastes of all kinds must be excluded under the direction and at the expense of the water supply. In some cases, by discouraging public sewers and by inspecting and cleaning middens at frequent intervals, contamination may be avoided. Especial attention must be given to vaults in the winter when the ground is frozen for at such time if vaults are too full, their contents may overflow and reach the water at the first thaw. In some cases it may be necessary to construct a sewage disposal system to care for the sanitary sewage of the place. In all such cases a clear, well oxidized effluent should be produced and chlorinated.

Storm water passing through a village will necessarily carry impurities. Rough filtering or screening may be required and care must be taken not to locate a water works intake within the influence of such storm water stream.

It is better to purchase and remove cottages from the immediate shores of a lake or reservoir. Pending such action a palliative is an efficient pail system.

Use of Watershed.—Certain portions of a catchment area which it may be advisable to purchase, in order to control its uses and occupation, and which can be profitably farmed, may be leased to agriculturists giving first choice to the former owner or occupants. Such rental would be subject to specified conditions under the constant and immediate control of the water supply authorities. This will mitigate in a large measure the opposition of some who do not wish to move from the locality preempted.

Reforesting.—Without doubt, especially in a rugged country, a forest will afford the best cover for a catchment area of a surface water supply. Planting along streams will assist in preventing erosion of the land as well as formation of bars and deltas in the reservoir with the consequent loss of storage. It is well to maintain a bare strip a little above high water mark above which the littoral planting for possibly 100 yd. or more in width may well be of conifers, for leaves of deciduous tress would fall or blow into the water.

It has been suggested that when large tracts are to be reforested, nut trees and shrubs bearing berries be planted to furnish food for birds and other small wild life. Valuable woods such as black walnut flourish in some localities.

Many articles on the preservation of forests have stressed the prevention of erosion, the minimizing of floods and the relative constancy and uniformity of run off from forested as distinguished from denuded areas. These are all arguments for reforesting a catchment area and indicate that a wooded area will make a storage reservoir of

given capacity more efficient by flattening the irregularities of the supply curve. Such a forest should be planted with reference to the exposure and soil conditions best fitted for various kinds and varieties of trees.

Lanes about 50 ft. wide should be left clear as fire stops and where possible these should be so located that they may later be used as roads in lumbering, for it may be anticipated that with the increasing scarcity of timber these trees will, in the years to come, produce a valuable commodity and a considerable income.

Roads. — Good serviceable roads should be provided to make the territory accessible and, if the public is to be admitted, the municipality may treat it, in a measure, as a park and construct good roads, cutting vistas through the trees and running the roads to sightly lookouts where such scenic effects are available. Wayside springs may be developed as drinking fountains for travellers.

Camp Sites.—Where several miles from the point of diversion and limited by the local conditions, camp sites may be established either for automobile tourists or for those who may wish to remain for longer periods. These may be of various types, including parking space for those living in cars, tent sites and floors for those who bring canvas shelters, and forest cabins, more permanent in character, but in general housing a single party. Rustic comfort stations may be provided of the type used in the western parks and described in the U. S. Public Health Service report dated June 12, 1925 (Vol. 40, No. 24, pp. 1248-1258). At such a camp, a water supply should be sufficient to maintain the service and properly police the camp.

Fishing.—There has always been a difference of opinion on the safety and advisability of allowing fishing in a natural lake used as a reservoir. One position is that if boats and humans are excluded from the lake and its shores, they can not contaminate the water, hence they should be excluded and possible contamination avoided. Another group, nature lovers who enjoy the woods and streams and fishing, feels aggrieved at being excluded from their former haunts and are sure they have never harmed a lake as they themselves drink freely of it when on excursions in the neighborhood. It is difficult to see how fishing on the upper 5 miles in a lake 15 miles long where the water after two or three years storage is diverted at the lower end, can injure in any way the supply if proper sanitary measures are prescribed and enforced. The cost of service, maintenance, policing, etc., can be borne by small fees exacted for rentals, fishing permits, etc.

Hunting.—Shooting should in no case be allowed. Government reports state that small game and game birds are being exterminated. The remedy is in providing sanctuaries where they may find food and be unmolested. A large forested watershed incidentally provides such conditions while at the same time the absence of hunters reduces the fire hazard and makes the forest safe and more attractive to the great majority of visitors.

Bathing.—On sanitary grounds only it is probable that a limited amount of swimming in a lake or reservoir ten or fifteen miles away from the waterworks intake would not appreciably injure the supply but from aesthetic considerations bathing should be prohibited as most people are averse to drinking from another's bath tub.

Public Opinion.—The growth of cities and consequent need of public water supplies, and the increasing efforts of the population to escape into the country coupled with the ready means of transportation now at hand, presents a many sided situation which calls for broad consideration and a reasonable co-ordination of the interests involved. A certain public service company's engineer favored the entire elimination of flow over a beautiful waterfall because, based upon the traffic over a bridge below the fall, he figured the wasted water was costing about $5.00 a look. There are cases where an entire water supply might be properly utilized; it would be difficult, however, to convince the public that any private franchise or public use of Niagara power should be allowed to destroy the scenic attraction of Niagara Falls.

The same principle holds in a waterworks property. The supply may be assumed as a public necessity; the creation of the storage provision for compensation water to communities down stream and the protection of the catchment area should be hand in hand as a part of the cost of the proposition. It will usually require but a small additional expenditure to make the territory attractive and afford pleasure to many people.

If the public, made up of individuals, the same ones who eventually pay the bill, are shown consideration and afforded a beautiful forest retreat, distant views of the blue water reflecting sky and shore and a chance for a few of them to fish if they like, a pride will develop in "our waterworks," each one will become a booster and there will be the best possible co-operation in keeping things clean.

Watershed of Rochester, N. Y.—As an illustration of a well managed watershed, a small portion of which has been purchased, we may refer to the present catchment area of the municipal water supply, of Rochester, N. Y. The total watershed now in use is 66.2 sq. miles of which 48 sq. miles is tributary to Hemlock Lake, 12.4 sq. miles to Canadice Lake and 5.8 sq. miles to the Canadice outlet. Canadice Lake lies nearly 200 ft. higher than Hemlock Lake, and the outlet is a tumbling stream running through a quick watershed to the Hemlock outlet. From a low diversion dam in the Canadice outlet channel, a 5 ft. concrete conduit brings the Canadice water into Hemlock Lake from which the present conduits proceed to the city of Rochester about 390 ft. nearer sea level and 27 miles due north.

Hemlock Lake had a natural shore line about 15 miles long. For about 20 years, but little land was purchased and the cottages along the shore were served by a pail system operated by the city. In 1895-6, a strip 200 ft. wide from high water mark was purchased and other lands have been added from time to time. Last year the dyke across the foot of the lake was raised 5 ft. to furnish increased storage and considerable property at the head of the lake was flooded during high water. The total area owned by the city around and on the watershed of Hemlock Lake is 2,617 acres.

On Feb. 6, 1919, water was turned into Hemlock Lake from Canadice Lake. The land acquired in the Canadice Lake watershed amounts to 550 acres, and 350 acres have also been purchased in the Canadice outlet, making a total of 3,517 acres now owned on the catchment area. Patrol of the shores is maintained, and the washing of sheep in the lake, as formerly practiced, has been discontinued. Where formerly barn yards and heaps of waste were located on the banks of runs and ravines, buildings have been constructed elsewhere, partially at the city's expense and the unsanitary conditions thus abated. By closing a road along the east shore of Hemlock Lake a potential source of pollution was avoided. This was made possible by the co-operation of the local highway commissioner who had found this road difficult and expensive to maintain. When the cottages were removed there was no reason for the road, as it was paralleled by another and better road on higher ground.

Canadice water has always been chlorinated before its discharge into Hemlock Lake and since May 11, 1925, the entire supply from the domestic system has been chlorinated at Rush Reservoir, nine miles from the city. Taste or odor due to chlorination is not noticed in the water as the conduits discharge into two distributing reservoirs of a total capacity of 165 million gallons where there is at present over five days' exposure to the air. There is a large fountain in each reservoir through which about 25 million gallons pass daily during warm weather.

The city property at the foot of Hemlock Lake near the gate houses is landscaped and a picnic pavilion is provided and a grill upon which meat may be broiled. There is, of course, ample water supply, and comfort stations and parking space are provided. In addi-

tion to small parties and some organizations from the city, the place is frequented by organizations from the rural country round about. Its free use serves to create good feeling between the local inhabitants and the waterworks authorities.

In 1902 the city of Rochester began planting trees on the shores of Hemlock Lake. Since that time the work has been extended along the shores of Hemlock and Canadice Lakes and on other areas acquired on the immediate watersheds of these lakes. To date nearly 1,500,000 trees have been planted on about 1,250 acres.

Additional Watershed Proposed.—A project for increasing the water supply by a large addition to the present watershed through the construction of a dam in the Honeoye Valley has been approved by the New York State Water Power and Control Commission. The plan will increase the present Honeoye Lake from 4.5 to 15 miles in length and raise its normal surface 30 ft. The watersheds now utilized will be tributary to the new reservoir and form a part of the total area of 187 sq. miles. This may again be increased to 209 sq. miles by storaging water in a high parallel valley and bringing it into the reservoir through a 5-mile tunnel. The new project looks forward to an ultimate supply of 100 million gallons daily. The engineers who devised this plan were Harrison P. Eddy, Allen Hazen and Edwin A. Fisher, and in their report they say:

"A large amount of land will be required. This should be bought liberally to the end that the city may completely control its source of water supply, and hold it free from centers of population that will tend to impair its quality.

"The land to be submerged is mainly the bottom of the old lake valley which is now swamp land, uninhabited, undrained, more or less covered with forest, and not of great agricultural value. All the land to be flooded must, of course, be secured at the outset either by purchase or by eminent domain, and also a certain margin of minimum width around the lake. In addition to this, and somewhat optional, it is our recommendation that the city buy as far as it can at fair prices, large areas of land to protect the quality of the water. In some cases, buying farms that would be inconveniently situated with respect to roads will remove the necessity for building roads leading to them. The land to be submerged must all be secured before the dam is built, but acquiring other areas may extend over a long series of years.

"We believe that the marginal areas bought and held should be much wider than have been taken in the past, to the end that the great new lake to be now formed may be completely protected in its sanitary quality for water supply for all time."

It has been estimated that the land eventually taken will amount to between 30,000 and 40,000 acres. The southern portion of the territory is more rugged and excellently suited for forest. It is proposed to exclude the public from the shores of the northern part of the reservoir, while it has been suggested that the southern portion might be used more liberally while at all times being kept under careful supervision.

The elevation of the proposed lake or reservoir surface will be +830, while some of the country which it is proposed to acquire rises to elevation +2200. Beautiful views may be had from present and future roads. The farthest limit of the watershed is but 40 miles from the city as the aeroplane flies and the round trip by highway from Rochester around the reservoir may be accomplished through 90 miles of varied scenery in a few hours.

Aerial Survey.—For the purchase of so large an area and because of the difficulty and expense of surveying such rough and wooded country and mapping it in the usual way, an aerial survey and photographic map was decided upon. There were 529 original 8 in. x 10 in. negatives made at a scale of about 1,000 ft. per inch flying at 12,000 ft. elevation. These pictures will be "laid" and the map enlarged to a scale of 800 ft. per inch. Greater enlargements may be made of any details up to 100 ft. per inch. The weather was very uncertain, some re-flying was necessary on account of clouds, and it required from May to August, with the plane constantly ready for flight, to accomplish the few hours of photography required for the 205 sq. miles of area covered. In order to give scale to the map, the city has undertaken a first order triangulation survey of the territory, and has placed a series of visible ground marks at known locations on both high and low ground. In the pictures lot lines described in property conveyances are readily identifiable and a net consisting of these lot lines will be superimposed on the photographic map.

In this country a run, ravine, arroya or gully is colloquially known as a "gull." These gulls generally reveal themselves in the pictures as broad crooked lines of trees and shrubs. Forests have a mottled appearance due to tall and low trees while nurseries or plantings of our reforesting show a plain and uniform color due to the trees in the given area being of the same age.

In the protection of catchment areas, we should have a true map to show things honestly as they are. The treatment of the public in reference to the area should be just from every viewpoint. The water should be kept pure and the surroundings lovely as in nature. This will result in good reports of the system so that any virtue in the management will receive the praise deserved.

Acknowledgment.—The foregoing is taken from a paper presented at the Montreal Convention of the New England Water Works Association.

Detroit's $11,000,000 Airport

Construction is well advanced on the airport now being built by Detroit on a $6,000,000 site owned by the city. An additional $5,000,000 was voted at the November election. On the property already owned by the city, consisting of 250 acres in the northeast section of town, extensive grading and draining work has already been done. The first of several runways, 1,000 ft. long and 150 ft. wide, has already been constructed. The last of the concrete slab was placed on June 21. This concrete runway gives access to the southwest section of the L-shaped port and will be supplemented by others, affording take-off and landing facilities in all directions, under all weather conditions.

According to P. A. Fellows, city engineer, contracts have been let for the placing of 20,415 sq. yd. of concrete surface to be used as hangar aprons, taxiways and maneuvering space for planes taking on or discharging cargo. Much of this work is to border the combination exposition hall and hangar, a great steel and concrete building 1,000 ft. long and 200 ft. wide, the cost of which is estimated at $1,000,000.

In plan, the Detroit City Airport may be compared to the famous Croydon port at London, although when finished the Detroit plant will be far more elaborate and convenient. In its completed form, the airport will be featured by a wide esplanade leading motor traffic off of Gratiot Avenue directly to the Administration building, where passengers may buy tickets and obtain other travel services as conveniently as at the most modern railway terminals. Beyond the Administration building there will be a covered concourse where planes may be boarded in safety and comfort, without exposure to the weather.

The exhibition hall will flank the esplanade on the right; an equally large hangar will be located on the left. Every equipment for facilitating air traffic, day or night, is to be installed, thereby assuring both pilots and passengers the utmost in safety and regularity of service.

Four Massachusetts Water Properties Sold.—Community Water Service Co., through a subsidiary, Greenwich Water and Gas System, Inc., has acquired the water properties serving Dedham, Hingham, Scituate and Cohasset, Mass. The companies acquired are appraised at $4,805,900.

Prechlorination and Filtration

Experience at Plant of Newport News, Va.

By E. F. DUGGER
General Manager Newport News Water Works Commission, Newport News, Va.

OUR city is very fortunate in that the drainage area of our reservoirs is to a great extent uninhabited and covered with woodland, which gives a three-fold benefit:

1st. Contamination is minimized.

2nd. A uniform runoff.

3rd. The trees or woods serve as a wind break and by this means decreases evaporation.

There are two elements that prohibit deep storage in our section of the peninsula, first, the general low elevation of the land preventing the raising of the dams, and second, the danger of getting salt water from deeper excavations.

General Conditions of Supply.—We have three reservoirs and the one directly connected with the filtration plant, with a maximum elevation of 17.4, has a storage capacity of 844,000,000 gal., which without the normal yield from the surrounding watershed, will allow approximately 200-day supply based on our present consumption. With this number of days supply impounded, a great amount of sedimentation takes place in the reservoir.

Lakes or impounded streams such as we have are the natural primary settling basins, and with the extended storage in our lakes much of the matter in suspension has sufficient time to settle out in the lakes. This process, however, is of varying degrees of excellence, because of the effect of wind currents on the water, at times the silt or sediment in the reservoir is stirred up and again is put in suspension. On account of the flatness of the surrounding country, it is imperative to keep the springs and streams clear of leaves and sediment, as the water in these streams moves with such low velocity that sedimentation takes place to a great extent in them, and when the heavy rains come, unless the streams are clear, much of this sediment is washed into the lakes and considerable trouble arises from high color caused by tannic acid. As the result of systematic clearing of the springs and streams the water is usually very clear. The raw water average color is around 30, with an alkalinity of 85, turbidity of 10 p.p.m., and a bacterial count of 250 colonies per c.c. which makes a comparatively easy water to coagulate, settle and filter.

The introduction of coagulants in the raw water just ahead of its passage through the centrifugal pumps has resulted in a very thorough mixing of the water with the solutions.

Chlorine is first applied to the raw water in the suction line at the rate of from .3 to .4 p.p.m. prior to the application of alumina sulphate. This latter is applied at the rate of 9 to 10 p.p.m. The coagulation basin has a capacity of only 651,000 gal., but the rate of flow of the water through it is regulated by the use of baffles. The precipitate deposited in this basin has shown conclusively the great value of prechlorination. Before our adoption of this method it was not necessary to clean the basin more often than once in five or six months, but since we began prechlorination, the basin has done the work for which it was designed so much more effectively that it is necessary to wash the basin at least once every 30 days, even in the cold weather, else the precipitate becomes so heavy that it breaks up from the bottom and floats on to the filter beds. Previous to prechlorination the filter beds were compelled to do the work now done in large measure by this coagulation basin which necessitated excessive washing and continuous boosting.

After sedimentation the water flows from the basin by gravity on to eight rapid sand filters of 1,000,000 gal. capacity each, under which is located the clear water well with a capacity of 235,000 gal.

On Jan. 1st, 1923 we felt that our filtration expense was unusually large compared with the results obtained. During the year 1922 the annual output of the filter plant was 1,568,000,000 gal. of water, at an expense, which included the wash water, of $19,664 or $12.53 per million gallons. During this period from January through November we were using 22 per cent alum. But for the month of December, for experimental purposes, we used 17 per cent alum, and the floc obtained with this 17 per cent coagulant was far superior to that which we were obtaining with the 22 per cent, and this item alone meant a considerable reduction in our operating expense.

Results of Prechlorination. — In August, 1923, after the recommendation of A. L. Gammage, Consulting Chemist of the firm of Weston and Sampson, of Boston, Mass., we began prechlorination with the immediate result of a much finer and denser floc with a still greater reduction in the amount of alum. In a short time we also noticed a material increase in the length of filter runs, a decrease in the percentage of wash water and an increase in gallons of water filtered, and a material decrease in the bacterial count in the applied water.

Prior to prechlorination we had considerable trouble with our filter beds. At the end of practically every run cracks would appear in several places in the beds and in several instances the sand would actually pull away from the sides. In washing, hard spots would be visible over the bed which would necessitate considerable labor expense in breaking them up. This trouble has now practically disappeared and the filter beds have a smooth surface with very rarely a hard spot.

We use two independent chlorination plants at all times and this naturally gives us greater assurance of perfect results in the disinfecting process.

The long reacting period of coagulation basins and the chlorine absorbing capacity of the filter beds at most plants permit relatively large overdoses of chlorine without having free chlorine in the filter effluents. This is of practical value, in that when the rate of filtration is lowered it is not necessary to reduce the amount of chlorine applied as the beds will absorb all excess. In fact, the dechlorinating capacity of the filters makes the preliminary chlorination of the raw water comparable to superchlorination.

Comparison of Results.—Table I is a comparison of results in the filtration department for the year 1922, which was prior to prechlorination, with that of 1928.

Costs.—The total expense for the operation of the filter plant for 1922 as previously stated, amounted to $19,664.15 or $12.53 per million gallons. Total operating expense of the Filtration Plant for the year 1928 was $11,570.44 or a total cost of $7.65 per million gallons, which was a net saving in operating expense of $8,093.71 per year or $4.88 per million gallons.

In addition to prechlorination sufficient chlorine is also applied to the filtered water to give a residual of .20 to meet State Health requirements.

The average depth of our reservoir is 8½ ft. with a total flooded area of about 500 acres. With the warm climate the conditions for algae growth are ideal.

Ackowledgement.—The foregoing is an abstract of a paper presented at the First Virginia Conference on Water Purification and Sewage Treatment.

Table I

	1922	1928
Gallons of water filtered	1,568,851,563	1,511,951,662
Daily average	4,292,744	4,142,333
Total pounds of Alum	216,889.77	150,300.86
Total pounds of Chlorine (Raw)		10,518.08
Total pounds of Chlorine (Filtered)	5,863.22	4,083.64
Alum G. P. G.	.964	.69538
Chlorine G. P. G. (Raw)		.0487

The Electromagnetic Theory of Air Circulation

In "Municipal News and Water Works," October, 1928, the editor outlined his electromagnetic theory of permanent and migrating cyclones. It was shown that there are 12 permanent cyclonic whirl centers, 6 in each hemisphere, 6 near the equator and three near each pole. The 6 great whirls in the northern hemisphere rotate anticlockwise, while the 6 in the southern hemisphere rotate clockwise. In the article above cited the rotation was erroneously given in the reverse direction.

Each of these 12 permanent cyclones has a corresponding anticyclone, for each ascending whirl bends over and descends, forming an inverted U. This inverted U also characterizes the migrating cyclones that cause our storms.

The editor finds that the three permanent cyclonic whirls whose centers are near the arctic circle, descend as anticyclones somewhat north of the Tropic of Cancer. Similarly the three permanent cyclones whose centers are near the antarctic circle descend as anticyclones near the Tropic of Capricorn. These 6 permanent anticyclone centers lie somewhat to the east of their corresponding cyclonic centers.

In Clayton's "World Weather," p. 40, on a chart of permanent "highs" and "lows" will be found many of the 24 centers above mentioned, and on his p. 19 their effect on ocean currents may be discerned.

It will be noted that this electromagnetic theory of air-whirls and the resulting circulation of the atmosphere differs radically from any theory hitherto advanced. It explains not only the migratory cyclones but the permanent air currents, and it does this without appeal to correction or to differences in centrifugal force on the earth.

The permanent cyclonic whirls increase their intensity and expand in diameter when sunspots increase in number. The ascending cyclonic whirl, being then more powerful, rises to a greater height and descends as an anticyclone at a greater distance from the original cyclonic center, and is also greater in diameter.

Many rainfall paradoxes are readily explained by this theory. For example, the summer monsoons of India bring much rain when sunspots are few, whereas little rain, frequently accompanied by famines, occurs during sunspot maxima.

An anticyclonic whirl that comes from the cyclonic center in the Philippine Islands exists to the west of the latter. In summer it ordinarily causes strong southwesterly monsoons in India, but when sunspots are very numerous its center moves so far westward that these monsoons become very weak. In winter its center moves so far eastward that the northeasterly winds from an anticyclone in Asia predominate. Hitherto this seasonal change in direction of the Indian monsoons has been attributed to convection currents caused by the differences in temperature of the Indian ocean and the land. Similar incorrect explanations have been given of other monsoon winds; for example, those in the United States. Two anticyclonic whirls control these, one centering in the Pacific and one in the Atlantic. The latter is the anticyclone whose cyclonic origin is the whirl that centers near Timbuctoo, Africa. The former has its cyclonic center near the Bering Straits.

The 24 permanent cyclones and anticyclones explain the westward flow of the trade winds within the tropics and the eastward flow of the winds in temperate zones. Also the equatorial calms and those of Cancer and Capricorn are explained thereby.

It should be noted that the permanent cyclonic whirls are whirl-belts, and that relative quiescence exists inside these belts.

In addition to the 24 permanent whirl centers above mentioned there are two others, one at or very near each pole. The one centered at the south pole is clearly cyclonic, the barometer being abnormally low in Antarctic regions. The one centered at the north pole is less clearly cyclonic, and this may be due to a stream of descending air that comes from the great Antarctic cyclone.

One of the by-products of this electromagnetic theory of air movement is that it furnishes an admirable explanation of an enigma that has long puzzled geologists, namely the existence of vast ice caps in low latitudes at times when mild weather existed near the arctic circle. The electromagnetic whirl-belt theory explains such phenomena thus: A very great outburst of sunspots would so concentrate free electrons on the earth as to result in greater intensity of all the permanent whirl-belts. Their great expansion would move certain of these belts into low latitudes; while within those belts there would be relative calm. We see just that condition today inside the whirl-belt whose center is near Timbuctoo, Africa; for there the calm is so extensive that winds do not sweep inward either from the Atlantic or the Mediterranean. It should be noted that this African whirl-belt is the most powerful of all, judged not merely by its present diameter but by its diameter when it raised the mountains that flank the Pacific slope of North America. In the latter case, it was a molten whirl-belt of cyclonic nature that produced this vast crustal uplift, as outlined in the article above mentioned.

For a century meteorologists have complacently dismissed from serious consideration all suggestions that electrodynamics is much of a factor in their realm. Facts, however, point more and more strongly toward electromagnetism as being the greatest of weather factors. This will become increasingly evident in a forthcoming series of editorial articles in this magazine.

Some Remarks on Logic

Two of the oldest—perhaps the two oldest—sciences are mathematics and logic. In some respects they are closely related. In fact all of syllogistic logic can be expressed in the form of equations that serve as premises and are combined to produce the conclusion of inference. However, there is much more to logic than the syllogism, much more than a science of the use of words as a tool of thought. Yet even if there were no more than its verbology, logic would be well worth studying as such.

A part of logic is learned as a by-product of other studies. The same is true of mathematics, yet it is seldom urged that all of mathematics should be learned thus. It is rather surprising, therefore, that there is such a general belief that logic need not be studied as a science by itself. Perhaps the main reason for the prevalence of such a belief is to be found in the character of the text books on logic. Among the best of these is Bain's "Logic," a 700-page book, published by the American Book Co. Written 60 years ago by Alexander Bain, professor of logic in the University of Aberdeen, it is as good as any later treatise written for the beginner. Although all other sciences have marched many a league in the past 60 years, logic has virtually stood still. This very fact points toward some defect in the science of thinking, and perhaps it is the very defect that has led to its decadence.

Herbert Spencer rightly contended that logic should teach certain broad principles relating to matter, for reasoning relates mainly to matter. But practically all logicians have erroneously followed Hamilton's dictum that logic is concerned only with certain laws of thought and their application. Moreover, if there are any laws of thought relating to research and invention, which Hamilton doubts, the logicians are almost unanimous in declaring them not to lie within the province of logic. So, logic, as thought, simmers down to a sort of glorified grammar, which, however useful, is deadly dull. Even as to its utility, doubts may arise; and many a philosopher has vigorously expressed such doubts. Bacon ridiculed the barrenness of Aristotelian logic, and he was not the first to do so, nor by any means the last.

Niell, following Bacon, undertook to reduce inductive (or research) thinking to rules; but did little more than rephrase certain rules that Herschel had printed in his "Discourse on the Study of Natural Philosophy." Neither Bacon nor Niell ever applied the research rules that they laid down, so they failed to see how barren most of them are unless guided by certain principles of which they were ignorant, but of which the real discoverers, like Galileo and Newton, were aware.

Now comes a very curious fact, namely that the greatest of discoverers have rarely laid down a single research rule or principle that is not either self-evident or so vague as to be useless. This fact has often been commented upon. In his "Philosophy of the Human Mind" (an admirable book, written more than a century ago) Dugald Stewart said: "But the language of this great man (Newton), when he happens to touch upon logical questions, must not always be too literally interpreted. It must be qualified and limited, so as to accord with the exemplifications which he himself has given of his general rules." Stewart then refers specifically to Newton's erroneous research rule: "I form no hypotheses * * * Hypotheses have no place in experimental philosophy." Newton's every discovery was based upon some analogy, which inevitably led to an hypothesis, even to that grand hypothesis that the "occult force" gravitation extends beyond the earth to every particle in the universe.

Similarly the research rules given by that other genius, Descartes, are almost all either erroneous or self-evident. When two such men make so poor a fist in writing about their methods of research, there seems to be some truth in the common belief that scientific discovery is an art that can not be taught. However, let no one be hasty in coming to such a conclusion. Very often the men who are busiest in some performance, whether manual or mental, are least capable of instructing others.

Dugald Stewart has to his credit a more comprehensive understanding of the most important principle of research than we have found in the writings of any contemporary or predecessor. He points out that scientific hypotheses are usually based on analogies, and that without hypotheses, the research scientist usually makes little progress. Thus he takes issue with Bacon and with Newton, refuting the latter by pointing to numerous hypotheses that guided his experiments. Stewart barely falls short of insisting that all reasoned-out discoveries have been based on hypotheses that were in turn based on analogies. This generalization, we believe, is true, and failure to perceive its truth has immeasurably retarded the progress of science. Whewell, throughout his monumental "History of the Inductive Sciences" and his later works, also just missed this generalization; and missing it, he formulated a very vague and barren hypothesis respecting the nature of research. Neill, in his "Logic," missed it completely; but a contemporary of Niell, and a more original logician, Stanley Jevons, came very close to a full recognition of the use of analogy in forming hypotheses. In his "Principles of Science," p. 283, he says: "Generalization passes insensibly into reasoning by analogy, and the difference is but one of degree. We are said to generalize when we view many objects as agreeing in a few properties, so that the resemblance is extensive rather than deep. When we have two or only a few objects of thought, but are able to discover many points of resemblance, we argue by analogy that the correspondence will be even deeper than appears." Notice that Jevons says "many points," instead of saying "one point" of resemblance. He just misses seeing that any two phenomena that resemble one another in one respect invariably have other points of resemblance, hidden, it may be but discoverable if we will but follow up the clue furnished by the one point of resemblance.

Jevons (p. 286) says: "There can be no doubt that discovery is most frequently accomplished by following up hints received from analogy, as Jeremy Bentham remarked." Again Jevons fails to see the generality of this rule, or he would have said "always" instead of "most frequently." He is speaking of scientific discovery, and not of accidental discovery; but even accidental discoveries in the realm of science are rarely made by men who have not already formulated some hypothesis, whose truth the "accident" suddenly makes more probable or perhaps certain.

W. P. Gillette

Book Reviews

"Governmental Purchasing," by Russell Forbes, Secretary, National Municipal League; Sec., Governmental Research Association, etc. First edition, 370 pages, 6 in. by 9¼ in., cloth cover, hard binding. Harper & Brothers, New York, publishers. Price, $5.00.

This volume represents a five year study of the functioning of purchasing systems in the federal, state, county and municipal governments of the United States and Canada. No attempt has been made to recommend a "model" purchasing system or to devise "model" forms for its administration because the widely varying legal requirements and local conditions demanded peculiar modifications and precise adjustments in the individual government. Instead, the author has attempted to present a synthesis of the best existing practice, illustrated by representative forms in actual use, of each of the various steps of the purchasing system in which the purchasing office plays a role, from the receipt of a requisition or an estimate of requirements from the using agency, to the approval of the claim for payment. As a further assistance to the practical application of centralized purchasing the author has compiled a representative set of laws, examination questions for the selection of a purchasing staff, salary standards, and other data which are presented in the appendices.

"Stresses Statically Determined," by John Clayton Track, Professor of Civil Engineering, Sheffield Scientific School of Yale University, M. Am. Soc. C. E. First edition, 462 pages, 10¾ in. by 7¾ in., cloth binding. John Wiley & Sons, Inc., New York, publishers. Price, $6.00.

This book was designed to give a thorough working knowledge of the theory of stresses in statically determined framed structures. Considerable attention has been given to explanations of fundamental conceptions, principles and methods, thus permitting the student to master them easily and quickly by himself.

One important statement made in the text follows:

"In any general method of attack, whether it be a problem in stresses or a problem in any other type of engineering work, there are three main steps, namely: (1) To determine what is known, (2) to determine what is unknown or required, and (3) to solve the problem by working from the known to the unknown by some correct and efficient method." The author states that in the subject of stresses there are only eight different types of problems which commonly arise: two in concurrent forces, two in parallel forces, and four in non-concurrent forces. He states, further, that any given problem will fall usually under one of these eight cases according to the number and nature of the unknown elements. Hence, the unknown elements well determine the case.

The book is mechanically arranged for the advantageous use of the material in that diagrams which are being discussed in the descriptive matter is usually before the reader at all times without turning pages. All material is excellently arranged. Illustrative problems clearly demonstrate the point under discussion.

"Field Engineering," by William H. Searles, C. E., Late Mem. Am. Soc. C. E. and Howard C. Ives, C. E., Civil and Consulting Engineer. Twentieth edition, 350 pages in text and 386 pages in table sections, 4⅛ in. by 6¾ in., gold edged, flexible binding. John Wiley & Sons, Inc., New York, publishers. Price $4.00.

A chapter on highway curves has been added to the regular handbook in producing this addition. The treatment is not exhaustive and should have been accorded greater length and more discussion to make it the new section of the equal standard with the remainder of the book. No mention has been made of superelevation or curve widening, both of which should receive discussion in the text.

A point of weakness in the book is the lack of an index. There is a table of contents in the front but to be real usable and act as a handbook this volume should contain a detailed index.

"Structural Problems," by C. R. Young, B. A. Sc., C. E., Mem. Eng. Inst. of Canada, Mem. Am. Soc. C. E., Prof. Structural Eng'g. Univ. of Toronto. First edition, 230 pages, 6 in. by 9 in., cloth binding. John Wiley & Sons, Inc., New York, publishers. Price, $3.50.

This book is written with the point in mind that many students and designers prefer to check their understanding of an unfamiliar theory closely following through an illustrated example. The problems presented do not in any sense constitute a treatise or a complete systematic development of the subject, but merely indicate the method of applying elementary structural theory to the design of characteristic structures, members and details.

The reader is assumed to have a sound basic knowledge of statics and mechanics of materials. Consequently the computation of stresses necessary in the design of the structures has, wherever practicable, been dealt with briefly.

Most of the formulae have not been developed. They are stated only and references have been given in places, to standard texts dealing with structural mechanics and the theory of structures. The book is in its nature supplemental to text books on the theory of stresses and structures.

The author states that the following features are new in printed book form:

1. Determination of the net section of riveted tension members.

2. Determination of the thickness of base plates for riveted steel column bases.

3. Computation of the anchorage of columns subjected to overturning.

4. Determination of rivet tension in column brackets and beam connections.

5. Design of a cantilever shelter truss.

6. Design of a stationary jib crane.

Complete design of a timber bent for a flume trestle.

"Chemistry in Medicine," edited by Julius Stieglitz, Professor of Chemistry, University of Chicago, with Board of Advisory Editors. First edition, 757 pages, 5½x7½ in., flexible leatherette binding. The Chemical Foundation Co., Inc., New York, publishers. Price upon application to publishers.

This book presents to the public as well as to the practitioners of medicine the great possibilities for advance in medical science through further intensive cooperation between chemistry and medicine. Chemistry is the fundamental science of the transformation of matter, and our life, from our inception to our return to dust, in every breath we draw and in every moment we live, is indissolubly connected with most complex transformations of matter.

Each different subject in the text has been written by a specialist on that subject. Physician, physiologist, pharmacologist, bacteriologist, pathologist and chemist have united efforts in the production of this excellent volume. The following chapter headings give an indication of the type of contents:

I. The Significance of Chemistry and of Its Methods of Attack on Fundamental Problems.

II. Heredity and Development.

III. The Human Body As a Machine.

IV. The Story of the Discovery of Vitamins.

V. The Conquest of Dietary Diseases.

VI. Chemical Regulators of the Body.

VII. The Policing of Civic Life in the Laboratory.

VIII. The Alleviation of Suffering.

IX. The War on Invading Germs.

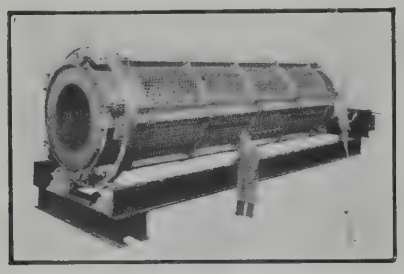
X. A Hope of Mankind—Chemo-Therapy.

"International Airports," by Stedman S. Hanks, Lt. Col., Air Corps Reserve. First edition, 195 pages, 5¾ by 8½ in., hard cover cloth binding. The Ronald Press Company, New York, publishers. Price, $5.00.

This is a discussion of airport construction and facilities told in a narrative style. Various airports of Europe and America are described. Methods of handling passengers and freight are discussed. Lighting, communication, management and insurance are items treated in the book. The many illustrations show airport arrangements much better than word descriptions. The author traveled to all of the principal airports of Europe by airplane. His discussion is the result of first hand impressions.

All Roller Bearing Screens

In the new plant of the Van Camp Sand & Gravel Co. at Lebanon, O., every piece of machinery will be equipped with antifriction bearings. One of the screens, a 72-in. Telsmith-Hercules, built by the Smith Engineering Works of Milwaukee, Wisconsin, is



New Telsmith Roller Bearing Equipped Gravel Screen

equipped throughout with Dodge-Timken roller bearings and has a capacity of 300 cu. yd. of sand and gravel an hour. It has an extra heavy frame, all gears are enclosed and special protection is provided for the bearings.

The Van Camp plant, which is rapidly nearing completion, will have a daily capacity of 3,000 cu. yd. of washed sand and gravel. The 72-in. screen will be used as a scalper to precede two 60-in. Telsmith-Hercules washing screens, one of which will be used for classifying gravel and the other for the production of crushed stone. Arrangements are provided for diverting the flow of material from one screen to the other as may be necessary. These two 60-in. screens are also being built by the Smith Engineering Works and equipped with Dodge-Timken roller bearings.

Concrete Tree Trunk Park Incinerator

To eliminate the objectionable feature of daily collecting rubbish from refuse cans and to provide a receptacle rather more attractive than the usual refuse container, there has been developed a reinforced-concrete incinerator, designed to resemble the trunk of a tree. They are in use in a number of cities, about 350 of these incinerators having been placed in Central and Riverside parks in New York City. Each receptacle is provided with a grate at the bottom, so that the park attendant merely burns the contents each evening. There are two holes directly under the grate to permit draft and to allow removal of ashes. The interior of the incinerator is lined with fireclay. These incinerators have been developed by the Municipal Products Company, Grand Central Terminal Building, New York City.

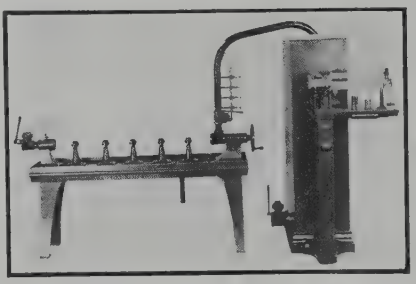
Tree Trunk Type of Incinerator of Reinforced Concrete

Clark Meter Testing Machine Improved

A slight change has been made in the Clark Meter Testing Machine for testing the accuracy of water meters.

The electric alarm bell which has been used to signal the closing of the test on water meters has been replaced by an electric buzzer. In several cases where the Clark Meter Testing Machine was located near the telephone, it was difficult to distinguish between the bells.

The electric buzzer on the Clark



Clark Meter Testing Machine

Meter Testing Machine is quite an aid in the testing of meters on small flows.

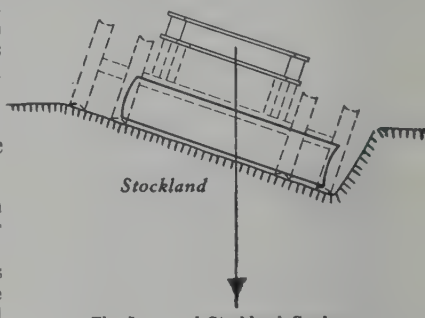
In testing on a small flow or on quantity tests for accuracy, the operator may leave the machine and occupy himself with other duties. The electric buzzer calls the operator a few seconds before the close of the test.

Stockland Improves Grader

One of the design features of the Stockland road grader is its low center of gravity with plenty of blade clearance. This, the manufacturer states, is strictly a Stockland feature which has been carefully worked out by the engineers who are constantly working to give the users of road graders efficient equipment.

Because of this low design, it might appear that there would not be enough blade clearance. It is claimed, however, that all Stockland graders have a blade clearance equal to graders built higher from the ground, and yet have all the advantages of a low center of gravity design. The circle assembly can be raised the full height of the frame if necessary.

The center of gravity comes directly through and very close to the center of the cutting blade when on a 2 to 1 slope. As the design of a grader is made higher, the perpendicular line drawn from the center of the grader frame down through the blade will come correspondingly closer to the outside edge of the blade instead of the center when on a slope.



The Improved Stockland Grader

Some of the other design features claimed for the Stockland grader are the cut-lift-roll curved blade, proper location of blade, extra long wheelbase, three-point suspension, fewer working parts and heavy frame construction. All of these interesting features are dwelt upon in the new Stockland S-100 Grader Book.

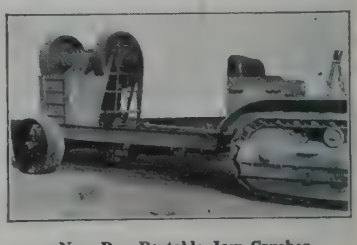
Foote Bros. Gear & Machine Company, 111 N. Canal St., Chicago, Ill., who have recently taken over the Stockland Road Machinery Company, Minneapolis, Minn., will be pleased to send you one of these Grader Books upon request, without obligation.

Tractor Drawn Crusher Announced

The new Day Jaw Crusher, manufactured by the Day Pulverizer Co., of Knoxville, Tenn., is driven direct from a Caterpillar power take-off.

It can be attached in two minutes as the drive assembly has two universal joints and there is no delay for alignment. It is fed from the side and may be moved forward as it crushes.

Adjustments are easily made for any size material while the machine is in operation. With its short turning radius, simplicity and ruggedness of construction, it provides to counties and various others a most economical machine as it provides crushed materials right on the job.



New Day Portable Jaw Crusher

Water Works and Sewerage

Vol. LXXVI SEPTEMBER, 1929 No. 9

New Service Building of the Portland Water District

New England Water Works Association Holds Annual Meeting at Portland

Program of 48th Annual Convention of Association

THE 48th annual convention of the New England Water Works Association will be held at Hotel Eastland, Portland, Me., September 17, 18, 19 and 20.

The convention office of the secretary will be located in the lobby on the first floor, Hotel Eastland, and will be opened for registration at 3 p. m., Monday, September 16. The registration office will not be open evenings after 6 p. m.

Technical Meetings and Exhibits.—The exhibits will be located in the Sunrise room of the hotel. Technical sessions will be held in the ballroom and other rooms as posted. Victor E. Arnold, of the Pittsburgh Equitable Meter Co., New York, is chairman of the committee on exhibits.

Transportation.—Portland is reached by three railroads, the Maine Central, the Boston & Maine and the Grand Trunk. No special arrangements have been made with any of the railroads for transportation, as many of the members of the association wish to go to Portland by automobile.

Electric car lines serve the city and its suburbs, and give first-class service to the beaches and near-by resorts. Portland's airport, in the town of Scarboro, about six miles from the center of Portland, is one of the largest and best equipped in the east.

Program.—The program, as arranged by the program committee, of which Robert Spurr Weston is chairman, follows:

TUESDAY, SEPTEMBER 17

Morning Session, 10:00 a. m.

Address of Welcome by
His Excellency William Tudor Gardiner, Governor of Maine.
Lester F. Wallace, Chairman Board of City Councilmen, City of Portland.
William L. Blake, President Board of Trustees, Portland Water District.

Secretary's Report
Treasurer's Report
Editor's Report
Award of Dexter Brackett Medal
Committee:
Gordon M. Fair, Chairman
Frank A. McInnes
G. Earl Lourie

Closing of Polls
Appointment of Tellers

REPORTS OF COMMITTEES ON

Tests of the Bureau of Standards, Harry W. Clark, Director and Chief Chemist, Water and Sewage Laboratories, Mass. Department of Public Health, Chairman.

The Collection and Correlation of Information Concerning the Corrosion of Iron and Steel Pipes and Standpipes, Caleb M. Saville, Manager and Chief Engineer, Board of Water Commissioners, Hartford, Conn., Chairman.

Standardization of Pipe Flanges and Fittings, Wm. R. Conard, Conard & Buzby, Burlington, N. J., Chairman.

Entertainment.—Burt B. Hodgman, chairman of the entertainment committee, has announced the following program:

TUESDAY, SEPTEMBER 17

1:00 p. m.—Maine clam chowder luncheon at new shops of Portland Water District followed by inspection of shops and standpipe painting inspection. Ladies are invited. (Courtesy of Portland Water District.)

8:00 p. m.—Informal reception for ladies at Hotel Eastland.

8:15 p. m.—Theatre party for ladies. (Courtesy of Geo. F. West & Son.)

WEDNESDAY, SEPTEMBER 18

11:30 a. m.—Clam bake and sail, Casco Bay. (Courtesy of Water Works Manufacturers' Association, Inc.)

8:00 p. m.—Ladies' Reception and bridge at Hotel Eastland. (Courtesy of Water Works Manufacturers' Association, Inc.)

THURSDAY, SEPTEMBER 19

10:00 a. m.—Sight-seeing trip for the ladies. Buses leave Hotel Eastland 10:30 a. m. (Courtesy Portland Chamber of Commerce.) Followed by coffee at Portland Chamber of Commerce.

7:30 p. m.—Dinner-dance and entertainment at Hotel Eastland. (Courtesy of Water Works Manufacturers' Association, Inc.)

Golf Tournament.—(Time to be announced.)

FRIDAY, SEPTEMBER 20

10:00 a. m.—Shopping tour through Portland business district. (Courtesy of Portland Chamber of Commerce.)

Operating Experiences With New Water Softening Plant at Marion, Ohio

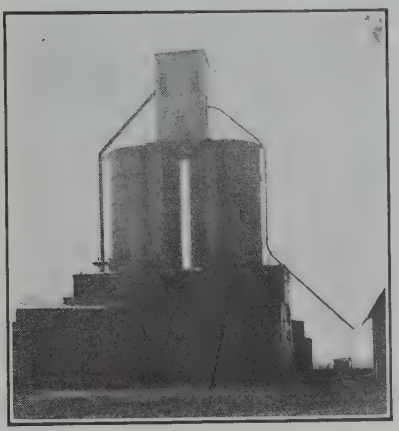
Double Carbonation Produces Effluent of Low Alkalinity

By MARTIN E. FLENTJE and CHARLES WHYSALL
Superintendent of Purification, Community Water Service Co.;
Chemist in Charge, Marion Water Co.

THE water softening plant of the Marion, Ohio, Water Co., a subsidiary of Community Water Service Co. of New York City, is unusual from several standpoints. Probably first of all is the extreme hardness of the water being treated; secondly, the use of all steel construction above ground; and finally in the application of double carbonation to produce an effluent of low alkalinity.

The Supply.—Water is at present obtained from 14 wells in limestone, varying in depth from 140 to 225 ft. Motor driven pumps deliver the water to collecting troughs leading to a concrete basin. During passage through these troughs and while spraying over small aerators, the raw water loses some CO_2 gas, and the dissolved iron is oxidized. Oxidization and precipitation of the iron results in an apparent turbidity of 150 p.p.m. in the collecting basin. Typical partial analyses of well waters are given in Table I.

The Softening Plant.—The water is pumped to the two 30 ft. in diameter mixing tanks, receiving on its way the milk of lime prepared in the headhouse. Browning-Montgomery chemical dry feeders are used. A 100 g.p.m. capacity



Chemical House and Chemical Storage Tanks; Airneyar Filter House

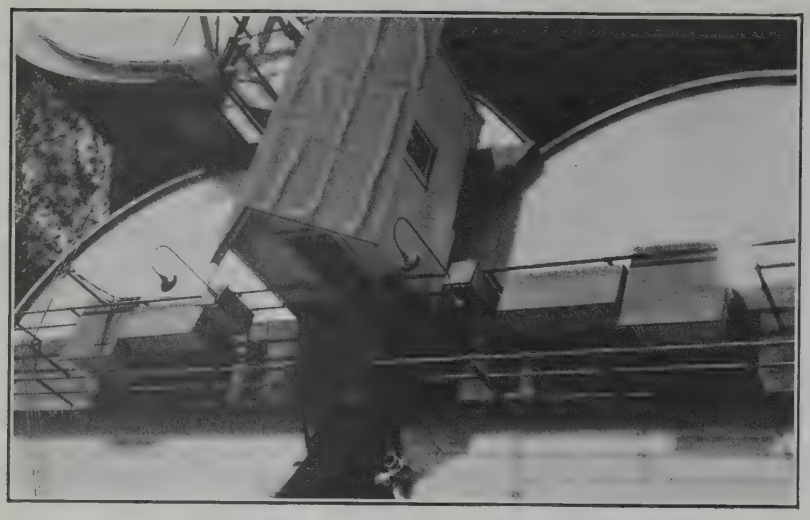
ejector adds the lime water to the water to be treated, while the former soda ash injector has been replaced by a small centrifugal pump.

Soda ash is applied at the top of the second mixing chamber. Marble Cliff (Ohio) Pebble Lime and Solvay Soda Ash are used. The mixing basins are 24 ft. in height, as are all other basins. A single paddle is located near the bottom, and is driven by a variable speed motor. Water enters tangentially at the bottom, spirals upward, overflows into the bottom of the second basin and repeats the process. The retention period in the mixing basins is 4-5 hours at the present rate of flow, with a minimum retention of 1 hour at plant capacity.

From mixing chambers, the water flows to the 120 ft. diameter Dorr Clarifier, flowing into the 30 ft. stilling chamber in the center 12 ft. downward, and then outward, finally overflowing into the launders at the periphery of the tanks. The sludge is removed from this clarifier by means of Dorr sludge pumps and contains between 65-75 per cent moisture.

The second settling tank is not equipped with clarifier mechanism, although the stilling well, etc., are arranged for its installation if found desirable. In this stilling well carbonation of the free lime present to normal carbonates is carried on, and some alum added. A retention period at plant capacity of 19 hours has been provided for in each basin; at present rate of

View of Water Softening Plant at Marion, O., Showing, Left to Right, Mixing Tanks, Dorr Clarifier, Final CO_2 Chamber and Settling Tanks



Mixing Tank and Sludge Pump House

flow 48 hours is the period. An effluent having a turbidity of 2 p.p.m. or less is produced in the Dorr Clarifier, with a final plant effluent turbidity of less than 1 p.p.m.

Final carbonation is carried out in a carbonating basin, 26 ft. in diameter with a retention period at present of 1¾ hours.

Chemicals are unloaded by vacuum, an Airveyor system being used.

Operation.—A number of laboratory tests indicated that with a lime dosage of 25 grains per gallon, or a theoretical excess of 6 grains; a minimum of soda ash required with a maximum hardness removed would results. Such a lime dosage insured complete precipitation of all the magnesium present, and eliminated some of the troublesome complex reaction products, commonly resulting in high alkalinities. This lime dose resulted in a causticity or free lime content of 30 p.p.m.—and this figure has been used as a guide in the treatment control. The soda ash dose is varied with the raw water hardness and to give any desired plant effluent. Typical analyses of various steps in the softening process are given in Table II.

Average operating results for various months are given in Table III.

Some operating difficulty has been experienced in preventing the clogging of the chemical feed lines. Sufficient diluting water has, however, solved this problem so well that the present lime line has not been cleaned for 8 months, and the cleaning time for the soda ash line has been extended from weekly periods to periods of 30 days.

Discussion of the proper place to carbonate to the normal carbonate stage led to an experimental installation of a carbonating grid at the influent to the Dorr Clarifier. This location was considered as practically identical with carbonation directly in the mixing basin effluent. The results of this experiment were quite unsatisfactory, as low alkalinities could not be obtained and very poor settling resulted. Higher causticities were apparently carried in the mixing chamber during the time of making this test and insufficient CO_2 gas added. Plotting the daily results, however, indicates that the poor results must have been due to some obstruction to the reaction between the CO_2 and the free lime—as at various times very high causticities have not resulted in high effluent alkalinities when the first carbonation was carried on in partially clarified water. Carbonating at this point also resulted in the formation of very small floc particles which would not settle readily. The turbidity of the plant effluent was increased from 1 p.p.m. or less to 10 or 15 p.p.m.

An inspection of Table III shows that a decrease in the pounds of soda ash per m.g. had occurred. This is probably due to increased time of retention in the mixing basins. A change in the rate of flow through the basins is apparently directly reflected in the soda ash required.

This decrease in soda ash required represents a saving of approximately $4.00 per million gallons, or an additional removal of approximately 30 p.p.m. hardness (non-carbonate) with the same chemical dose formely used.

Double carbonation has resulted in alkalinities averaging 30-35 p.p.m., whereas in laboratory tests without double carbonation, alaklinities below 65 p.p.m. could not be produced. Double carbonation has then resulted in a removal of 30 p.p.m. hardness at a cost of practically nothing, a constant

amount of coke being used, regardless of whether single or double carbonation is carried on. If, however, it is assumed that ½ of the total coke used is necessary to produce this result, costs would be as in Table IV.

Sludge disposal is rapidly becoming a serious problem and considerable study is being given this problem. No practical solution, however, has as yet been found.

The temperature changes taking place through the plant may be of interest. The well water has a constant year around temperature of 54 deg. F. During the winter the water in the basins gets as low as 37 deg.

The Marion Water Co. softening plant was designed by C. P. Hoover of Columbus and constructed under the direction of Geo. Whysall, manager of the Marion Water Co., under immediate supervision of Chas. Whysall, now chemist in charge.

Acknowledgment.—The above is an abstract of a paper presented at the 49th annual convention of the American Water Works Association.

Survey of Fire Hydrants in New Jersey

The recent survey of fire hydrants in North Hudson and Eastern Bergen counties covering 48 cities and towns supplied by the Hackensack Water Co. revealed a wide variation in the average spacing of these outlets of the water distribution system, according to a report made public by the president of the company, Nicholas S. Hill, Jr.

"In North Hudson County," says the report, "the extremes are West New York, 438 ft., compared with Secaucus, 781 ft., between hydrants.

"In Bergen County, the difference is more striking when one compares Edgewater, 352 ft., with Washington Township, 1,830 ft. It is, however, only fair to point out that Edgewater has large industries concentrated along a narrow belt of water front, whereas Washington Township is but recently opened to what promises to be a successful development.

"Taking all towns it is found that four have hydrants averaging less than 500 ft. apart, six have hydrants averaging from 501 to 600 ft. apart, six have hydrants averaging from 601 to 700 ft. apart, twelve have hydrants averaging from 701 to 800 ft. apart, five have hydrants averaging from 801 to 900 ft. apart, four have hydrants averaging from 901 to 1,000 ft. apart and ten have hydrants averaging over 1,000 ft. apart. The general average of all is 740 ft.

"The distances between hydrants over 1,000 ft. apart are, in the ten towns, 1,023, 1,070, 1,100, 1,150, 1,155 1,157, 1,204, 1,220, 1,392 and 1,830.

"If firemen must stretch two lines of hose, each at least 600 ft. long, to reach a burning dwelling midway between two hydrants 1,150 ft. apart, they are compelled to substitute the limited capacity of 2½-in. crooked hose for the far greater flow of an iron water main at least 6 in. in diameter which passes the dwelling and should properly have a hydrant connected to it at about that point."

Fire chiefs, the water company officials point out, are alive to the menace of such situations, and are on record as requesting municipal officials to order additional outlets attached to the existing water mains.

Symbols for Hydraulics.—The proposed American tentative standard symbols for hydraulics have been adopted by the sectional committee on scientific and engineering symbols and abbreviations and by the five sponsor bodies. The report is now being balloted by the American Standards Association. Copies of the proposed American Tentative Standard are available for review by those interested, and may be obtained on loan from the American Standards Association Information Service, 29 West 39th St., New York City.

Activated Sludge Practice in United States

General Features of Design and Treatment in Twelve Plants

EARLY in 1928 the Board of Estimate and Apportionment of New York City appointed a special committee consisting of C. W. Berry, controller, and Arthur S. Tuttle, chief engineer, to inspect methods of sewage disposal in use in other cities.

In all 16 plants were inspected as follows:

Chicago, Ill.—North Side.
Chicago, Ill.—Calumet.
Chicago, Ill.—West Side.
Chicago, Ill.—Des Plaines River.
Indianapolis, Ind.
Antigo, Wis.
Milwaukee, Wis.
Lodi, Cal.
Pomona, Cal.
Pasadena, Cal.
Long Beach, Cal.
Harbor City, Cal.
Los Angeles, Cal.—Hyperion (North Plant).
Grand Canyon, Ariz.
Houston, Tex.—South Side.
Houston, Tex.—North Side.

The object of the inspection was to secure information as to the applicability of the activated sludge process to a plant on Ward's Island; whether it might be a source of nuisance to the neighborhood; whether it was so far developed as to be dependable in operation; and whether it would prove an economical solution for the disposal of the tributary sewage.

Eleven plants employing the activated sludge process, and a twelfth where it is employed in part, were visited, while the other plants contained special features, such as fine screens and sludge digestion, that bear directly upon the New York City problem.

The salient features of the plants visited are reviewed by Kenneth Allen, sanitary engineer, office of the chief engineer of the Board of Estimate and Apportionment, in a report of the special committee. The notes following are taken from the report.

Coarse Screens.—Coarse screens are generally placed in front of pumps, fine screens, or other devices requiring protection from large floating material that might cause injury. The usual form is the inclined rack of parallel bars, spaced up to 5 in. apart and cleaned by hand, but in large installations some mechanical equipment is desirable.

At the North Side Works, Chicago, at Milwaukee, and at the South Side Plant at Houston cage screens are used in pairs, one being in service while the other is raised by power and cleaned by hand. These screens are adapted to large flows and deep sewers, when the limited amount of manual labor is justified.

At the West Side Works, Chicago, and the Hyperion Plant, Los Angeles, the Dorrco coarse screen is used. This is simple in design and mechanically operated, the curved rack being cleaned by a rake connecting the outer ends of radial bars rotating on a horizontal axis. This is a revival of a type of screen used in Germany and may well be adapted to many situations.

Fine Screens.—Fine screens of the Riensch-Wurl type are in use at the Des Plaines River Works, Chicago; of the Tark or Link-Belt type at Milwaukee; of the Dorrco type at Lodi, Pasadena, Long Beach and Los Angeles; and of the Hurd type at Indianapolis. Those at Chicago, Milwaukee, Lodi, Pasadena and Indianapolis furnish preliminary treatment for the activated sludge process, while at Long Beach and Los Angeles their function is to protect near-by bathing beaches. The Milwaukee, Indianapolis and Los Angeles installations are important as to size and are excellent examples of their kind. In general the trend seems to be in favor of slotted plates rather than wire mesh, and with 1/16 in. x 2 in. slots.

There are so many factors upon which screen performance depends that comparisons are difficult. Tests, unless made in parallel on the same sewage, are liable to be grossly misleading and it is a question whether there is a material difference in efficiency in the above standard types of screen. If a fine screen is considered preparatory to activation the choice of fineness will depend somewhat on whether the sludge is to be made into fertilizer, in which case it may be desirable to permit more solids to pass through, in order to increase the marketable product, but the cost of aeration will probably be greater. If the screen is for the protection of the waterfront the end to be sought is the removal of solids offensive to sight, and for this any one of the above screens operating with a slot 1/16 in. wide will serve the purpose. While, as stated, individual tests vary greatly, average removal of about 10 per cent of the suspended solids may generally be expected, but whether this is 5 per cent or 15 per cent the main object of screening has been accomplished unless further protection by chlorination is necessary, in which case a high removal of solids to reduce the cost of chlorine may be desirable.

The removal and moisture at these plants is shown in Table I.

In choosing a fine screen it would seem that too much stress has been laid in the past on efficiency as shown by short tests. Reliability of performance, durability, first cost and upkeep are believed to be matters of much more importance, and concerning these information is gradually accumulating with longer experience.

The disposal of screenings by burying in small quantities and in rural areas is often the simplest and best method. Where the volume is large, as at Los Angeles and Long Beach, or where the plant is in urban territory, as at Milwaukee, the problem is more difficult and a choice must be made of several possible procedures.**

At Milwaukee experiments in digesting the screenings and then mixing them with the sludge going to the filters are proposed. Whether this will affect the filterability of the sludge unfavorably or not remains to be seen. It will probably dilute to a small extent the nitrogen in the dried sludge but will also increase the volume of the sludge, as occurs when plain settled sludge from preliminary tanks is added to the output of activated sludge.

At Hyperion the Los Angeles screenings are buried in the sand but are exposed to a certain extent by the gulls that are attracted to the spot and some more satisfactory method of disposal is being sought. Experiments reported by D. C. Warfel have indicated that by distillation there may be recovered from one ton of screenings 85 per cent moisture, about 800 cu. ft. of gas containing 400 b. t. u., 100 lbs. fuel oil and 150 lbs. of fertilizer base containing 1½ per cent nitrogen, 3.2 per cent phosphoric acid and 1.0 per cent potash, valued at 1.50 per ton of wet screenings. These experiments are to be extended and the foregoing results must be considered provisional.

Long Beach appears to have solved the problem of disposing of its screen-

*Weighing 135 lb. and containing 20 lb. dry solids in 1925. This represents a removal of 2 p.p.m. out of 164 p.p.m. suspended solids in the raw sewage.

**The screenings from the New York City Canal St. and Dyckman St. plants are collected and disposed of with the much larger volumes of garbage. This seems to be the most satisfactory means of disposal under the circumstances, but where the wet screenings are dumped in large quantities into an incinerator, as attempted at the Jamaica plant, it has been found to interfere with proper combustion.

Table I

	Removal cu. ft. per m.g.	Moisture per cent	Disposal
Chicago—Des Plaines River	4±*	85	Dumped and buried
Milwaukee	7.5	90	Dumped
Lodi	12	87	
Pasadena	30	88	Buried
Long Beach	40	80	Burned
Los Angeles	16.5	87	Buried

ings satisfactorily. This is by incinerating in a home-made furnace with natural gas supplied by the municipality. Under existing conditions this is an economical and satisfactory method of disposal and one that deserves consideration when cruder methods are unsatisfactory.

Sedimentation Tanks. — In settling sewage it should be discharged from the tank, if possible, before it has a chance to become septic. Therefore contact with decomposing sludge or a long period of detention in the tank is generally to be avoided. Consequently, the plain sedimentation tank with mechanism for the prompt removal of the sludge has come into favor.

In the plants visited plain sedimentation tanks with hopper bottoms are found in one-half of the Des Plaines River Works at Chicago and at the South Side Plant at Houston, Imhoff tanks at the Calumet Works (for presettling) and at the West Side Works, Chicago, and at Pomona, and tanks with the mechanical removal of sludge at the North Side Works and the West Side Works (skimming tanks), Chicago, at Antigo, Milwaukee, Lodi, Pomona, Harbor City and Grand Canyon for final settling and at the Chicago North Side Works and the Harbor City plant for pre-settling as well. Tanks of this type are frequently called "clarifiers."

The Link-Belt clarifier consists of scrapers which push the sludge to a sump at one end of a long rectangular flat-bottomed tank. These "flight conveyors" are operated by endless chains on each side passing over sprocket wheels at the end. In their return at a higher level they may also serve to break up the scum or skim off the grease. This device is installed in the skimming tanks of the West Side Works, Chicago, and in the pre-settling tanks at Harbor City.

The Hardinge clarifier resembles the Fidler apparatus found in Germany, in which a spiral scraper rotating slowly in the bottom of the tank collects the sludge to an outlet pipe in the center. This device is to be installed at the North Side Plant at Houston and at Pasadena.

The Dorr clarifier, installed at the other plants employing mechanical removal, is similar to the Hardinge in that the sludge is gradually scraped to a sump or outlet at the center, but there are short scrapers set diagonally on four radial arms in place of a single spiral scraper. By a special mechanism one or more of these arms is automatically extended and withdrawn so as to collect from the corners of a square tank.

Each of the above types of tank has a field of usefulness: the tank with hopper bottoms and the Imhoff tank where their depth is not too costly, the hopper-bottomed and those mechanically cleaned where the sludge can be disposed of while fresh or held to decompose, as in separate digestion tanks, etc. The tanks of the clarifier type appear to be especially adapted to situations where excavation is costly, to final settling in connection with activated sludge or tricking filter plants or where removals of 40 or 50 per cent of the suspended matter is desired within relatively short periods. Sixteen separate digestion plants were installed in the United States in 1927 and 1927.

By digesting sludge the volume is reduced and the product is more readily drained or filtered and is free from objectionable odor. During the process methane gas of good calorific value is given off. By proper control of the acidity and temperature of the sludge the volume of gas may be materially increased. In Germany it has been sold to gas companies, at Birmingham it is utilized for power, and in the United States there are now several plants where gas recovery is an important feature. The largest of these has just been installed at Decatur, Ill., but that at Antigo, though one of the first, is of especial interest on account of its careful design and successful operation in spite of adverse climatic conditions. Gas collection may be used in connection with Imhoff tanks but more perfect control is possible with separate digestion tanks. The gas at Antigo is not utilized except to heat the sludge although a certain excess is available in summer. The gas produced at several plants is as follows (Table II):

Table II

Place	Cu. ft. per cap. daily	Methane per cent	B. t. u. per cu. ft.
Chicago—Calumet	0.4(0.1-1.1)	85	700
Atlanta, Ga.	———	———	700
Birmingham, Eng.	———	67	625-750
Essen-Rellinghausen, Germany	0.3	65-90	785-1010
Decatur, Ill.	.14-.51	70-80	700
Stuttgart, Germany	0.35	75.5	840-955
Antigo, Wis.	0.78	———	656

The amount of gas produced at Antigo is relatively high but in the opinion of the designer, Mr. Jerry Donohue, who has carefully watched its operation, "1 cu. ft. of gas per capita per day is not an unreasonable amount to expect where the design calls for a gas-tight digestor and where no leaks permit the escape of gas about the plant." So far as the above plants are concerned it would be a fair inference that under ordinary conditions at least 300 b. t. u. per capita could be recovered daily which, with coal at 12,000 b. t. u. per lb., would be equivalent to 4½ tons a year for every 1,000 persons. Where the sewage is strong, the cost for fuel is high, and sludge digestion is feasible, the recovery of gas for power, heat or lighting should be considered. The volume recovered will depend on the character of the sludge, being generally greater with strong domestic sludge and increased if mixed with activated sludge maintained at optimum temperatures and pH values and gently mixed by stirring.

Aeration Processes.—Of the plants visited pre-treatment at the Des Plaines River Works, Chicago, at Milwaukee, Indianapolis, Lodi and Pasadena is by fine screening. This includes the three plants where fertilizer is produced as, with the limited percentage of removal of solids desired, fine screens generally take less space and are less costly than tanks. In some situations, however, it is possible that shallow tanks providing a brief detention may be quite as cheap while serving as well for the removal of grease by skimming. At Houston the sewage is merely coarse-screened before aeration.

In the matter of aeration the "Manchester system" of spiral flow is adopted at the North Side Works and in one unit at the Des Plaines River Works, Chicago, at Indianapolis, Pomona and Harbor City, these being in general the newer plants. At Pasadena experiments have shown no advantages in spiral flow, probably due to the narrow width of tank. At Harbor City perforated pipes were adopted in place of diffuser plates for economical reasons in a temporary plant, but with apparently good results. At Pasadena the Norton plate has replaced the Filtros plate used heretofore, being durable and efficient and no more expensive. The experiments in mechanical agitation being conducted at the Des Plaines River Works have not been carried far enough to arrive at conclusions. In view of the very general adoption of diffusion by compressed air in the United States while in England much attention has been given to aeration by mechanical agitation, it is believed that experiment along these lines should be profitable in this country. This is especially the case, as a large part of the operating cost of activated sludge plants is due to the power used for aeration and agitation, while it is admitted that the efficiency is very low, most of the air escaping without change. Efforts looking to a more economical use of air seem likely to result eventually in lowering the cost of power, whether by more effective baffling, by decreasing the submergence of the diffusers, as is attempted at the Des Plaines River Works, Chicago, and at San Bonito, Tex., or by surface agitation.† An element of cost is the area required and as surface agitation implies shallow tanks it usually means a larger acreage which, to that extent, is a disadvantage. Climatic conditions should also be considered in the northern United States,

†Another method, called the "Stream-Flow Process," in which the natural aeration of a shallow stream is simulated, is described by Jenks and Levine on p. 381 of this issue of "Water Works and Sewerage."

where large areas of shallow tanks might present difficulties.

In the plants visited the amount of air required was generally between 1 and 2 cu. ft. per gallon of sewage, the lowest requirements being at Milwaukee (0.95), Calumet (0.9), Des Plaines River (1.25), Indianapolis (1.1), and Pomona (1.3), and the highest being at the two plants at Houston (2.0), and Grand Canyon (about 4). It will be noted that in general plants employing "spiral flow" use less air than those on the "ridge and furrow" system, but the bare figures may be grossly misleading without considering the other uses to which air is applied at the plant, such as for air lift (Grand Canyon, Houston) and sludge filters (Pasadena). The excessive use of air at Grand Canyon is due to the disproportionate capacity of the blower.

A strict comparison of cost between the several plants should also be taken with reserve as locality, size of plant and many other factors enter, but such as have been obtainable are given in Table III.

Sludge Disposal.—The disposal of sludge in lagoons, like the old-fashioned cess-pool, is not always a nuisance and yet cannot be considered ideal or free from possible odor. Where remote from habitations, as at Indianapolis and Houston, it serves without serious objection as an inexpensive expedient.

Prepared sludge-drying beds, as found at the Calumet and West Side Works, Chicago, Antigo, Lodi, Pomona and Harbor City, are less objectionable and with well digested sludge should be fairly free from odor. To prevent the spread of odor from fresh sludge the beds can be covered with greenhouse construction, as tried out at the Calumet plant, but this adds materially to the cost, and although it has generally been found to hasten drying, experience at the Calumet plant does not seem to have realized expectations, except in so far as it has extended the period when drying may be carried on. So far as known, covered sludge beds have not been adopted for any large plant, where sludge handling operations would offer special difficulties.

The success of the activated sludge process depends upon the building up of floc under aerobic conditions. The role of bacteria in the chemical changes that take place, which is generally considered of prime importance, is not definitely known and by some is not considered essential. But where the sludge is to be dewatered the amount and condition of the floc is a matter of vital importance. At Milwaukee the floc was formerly so broken up by centrifugal pumping as to be unfilterable. This was largely overcome by the substitution of plunger pumps. At the Des Plaines River Works, however, but little difference was noted between the filterability of sludge pumped by centrifugal pumps and that pumped by ejectors. A septic sewage is less amenable to flocculation than one that is fresh. In addition to this it is necessary to intensify flocculation by "conditioning" the sludge—that is, to increase coagulation by means of chemicals. For this purpose sulphuric acid has been generally used in the past at Milwaukee and sulphate of alumina at Chicago, but more recent experience at both plants points to the use of chlorinated copperas or ferric chloride. The choice depends in part on the cost and in part on the condition of the sludge. At Milwaukee all three of the above conditioning agents are used in turn, depending on temperature conditions: sulphuric acid in summer and chlorinated copperas in winter. Ferric chloride, tried at the Calumet plant, appears to be yet more effective in producing high rates of filtration but its cost has generally precluded its regular use. To promote filtration and drying, "Filter Cel," a diatomaceous earth, is used at Pasedena. Its effect is purely physical but it is effective in promoting filtration. For eastern plants freight charges would preclude its use, and a further disadvantage is in the dilution of the fertilizing ingredients of the product, "Milorganite" from Milwaukee containing about 7 units of nitrogen as compared with 5½ units in "Nitroganic" from Pasadena.

In the matter of dewatering, the modern Besco-ter-Meer centrifuge was found satisfactory in some respects with activated sludge at Milwaukee but was abandoned on account of the cost and the large amount of fine suspended matter in the effluent that had to be returned for treatment. After experiments with various devices the Oliver filter has been adopted at Milwaukee, the Calumet plant, Chicago, and Pasadena, the Berrigan press at the Des Plaines River Works, Chicago, and at the North Side plant at Houston an American continuous vacuum filter is being installed. By these devices the moisture is reduced to a point between 75 per cent and 80 per cent, so that further drying by heat can be economically carried out.

Table III

	Cost of activated sludge plant construction. Per m.g.d. capacity	Operation‡ per m.g.
Chicago—North Side	$ 97,000†	.....
Chicago—Des Plaines River	252,000††	.....
Indianapolis	40,500	$ 9.73
Milwaukee	99,000	16.80
Lodi	75,000	21.30
Pomona	80,600	25.90**
Pasadena	86,500	67.98**
Harbor City	37,000	.....
Grand Canyon	485,000*	475.60
Houston—South Side	22,000	13.15
Houston—North Side	24,500	17.50

†Exclusive of sludge digestion.
††Including experimental features.
*Including connection trunk sewer and outfall.
**Exclusive of revenue from fertilizer.
‡Exclusive of fixed charges.

The filter cake is dried in Atlas dryers at Chicago and Milwaukee and in Ruggles-Coles dryers at Pasadena. At Houston Buckeye dryers are being installed. The product from the dryer is ground, sifted and sold at Milwaukee at a net price, exclusive of freight, of of about $15 per ton,†† at Chicago $25 per ton, in carload lots, and at Pasadena $32 per ton, f. o. b. cars.

The manufacture of fertilizer from activated sludge requires considerable capital outlay and careful technical skill as well as educational work in building up a market, but the inherent value of the material is such that the revenue from sales under present conditions should about offset the cost of manufacture where transportation facilities are good and the market not too distant.

Chlorination. — Chlorination of the effluent is carried out at Lodi, Pomona, Pasadena and Grand Canyon, in the first three instances to protect irrigated land from any germs of disease that might survive and at Grand Canyon for the drinking purposes in place of the restricted water supply. The situation in each case is exceptional and the expense of chlorinating an activated sludge effluent from which practically all pathogenic organisms have been already eliminated would not under ordinary conditions be justified.

††$22.50 (more recently $25.00), including freight charges.

Uniform License Requirements for Plumbers

Uniform license requirements for plumbers in Bergen County would result in a reduction in building costs, according to M. W. Cowles, sanitary engineer of the Hackensack Water Co., Weehawken, N. J.

"One large item of expense to plumbers is the necessity of securing licenses in each community," Mr. Cowles says.

"In some cases this means the payment of a yearly fee; in others a bond must be deposited in addition. This condition sometimes arises because local plumbers wish protection against craftsmen from other communities where license fees are lower.

"Many builders require competitive plumbing bids, and cost of licenses frequently adds to the expense of the work. A plumbers' examining commission, county or state, would make it possible for any plumber so licensed to work anywhere in Bergen County.

"This would not in any way react unfavorably to the local man, who is in a position to do the work most reasonably."

The water company, Mr. Cowles says, advocates uniformity in plumbers' licenses as part of a generally uniform code of plumbing requirements in the seventy municipalities of Bergen County. Such a code, experts claim, would eliminate unnecessary building expense and safeguard health by requiring conformity to the latest plumbing practice.

Valuation of Public Utilities for Taxation

Impartial and Constructive Sketch of the Fundamentals of the Plan

By L. D. McPHERSON
Attorney at Law, Chicago, Ill.

THE constant concern of the people about the age-old and ever-present problems of property taxation warrants lively interest and continued discussion of means for improving the distribution of necessary taxation burdens.

Ambitious men are able to so disguise selfish propaganda as to make it appear to the voters that property tax burdens will be shifted to wealthy groups or corporations for whom it is difficult to arouse popular sympathy.

A full and fair discussion should lead the people to a clear understanding that this is a delusion and that it is futile for them to increase the property taxes of such groups and corporations because practically all of such increases will be added to the cost of capital or service which the people must use.

Under the laws of many states steam railroads and other public utilities are subject to ad valorem taxation. This requires a valuation. Under the laws of some states additional consideration must be given to the taxpayers' ability to pay.

In determining the valuation and basis for taxation of all such public utilities such items or elements as original cost, investment in facilities, cost of reproduction new, cost of reproduction less depreciation, capitalization, book value, development costs, going concern or market value of securities, either singly or collectively, should not be given controlling weight.

It is not the purpose of this article to discuss valuation for rate-making or for any purpose other than for taxation. It is here insisted that changes in valuation for taxation should not precede but should follow any changes in valuation for rate-making purposes only after the changed valuation has resulted in a change of rates. Such properties can not have any value which will not vary as their usefulness or capacity to earn varies. The question of the valuation of public utilities for purposes of taxation arises only in states where all property must be taxed on an ad valorem basis. Equity may construe this "ad valorem" value basis to mean commercial as opposed to investment or capital value.

In making a valuation of all such public utilities for taxation, little theory or speculation as to future rates, expenses or other factors should be indulged.

If the profitableness of the operation of such public utilities over a reasonable period of normal years is fairly ascertained, it is good evidence of its value when considered in connection with the prospects for the future and a chance to sell the property and business at a profit. The present and prospective worth of the services of the public utilities to those who will use such services may limit the value of such public utilities. Evidence of the value of such public utilities, whether monopolistic or competitive in character, should be but little, if any, different from evidence required to support valuations of other property. "The worth of a thing is the price it will bring." This embraces all the characteristics of each individual public utility by which it may be distinguished from other property, including relative desirability of ownership.

For taxation purposes the best evidence of the value of any public utility should be the financial results of operation of such public utility's property and business taken as a weighted average over a reasonable period of normal years for the property and business apportionable to the individual state. Before capitalizing the funds resulting from such operations, an interest rate which is high enough to hold necessary capital in the public utility industry should be increased by some percentage, or otherwise, to provide for taxes. Neither the past nor proposed taxes of a public utility should be used in the calulations. One step in the calculation might be to use the ratio of the general property taxes to the market value of general taxable property other than that of public utilities. For example, if it may be assumed that: (a) six (6%) per cent is an adequate interest rate; (b) the rate of general property taxes is $3 per $100 of assessed value; (c) general property is assessed for taxation at fifty (50%) per cent of market value, it follows that the six per cent for interest should be increased by one and one-half (1½%) per cent for taxes, making seven and one-half (7½%) per cent the factor by which to divide said funds to ascertain the approximate value of a public utility.

The justification for resorting to the methods of valuation herein discussed may not be found to exist as fully in the case of purely local monopolistic public utilities such as municipal water plants, local gas companies or in condition where contract ordinances fully define and provide for valuations for specific purposes.

Any method of valuation of public utilities for purposes of taxation should be flexible enough to provide equitable adjustment for, among other things, the following:

(a) The precentage, if any, of their net income which has been fixed as due the state by law.

(b) The part, if any, of the state's tax fund, which has been derived from payments made by a public utility, when such contribution to said fund partakes of the nature of a forced subsidy by the utility to the payment of interest or amortization of principal on public bonds issued or assumed for construction or other aid to competing public or semi-public facilities.

(c) Relative advantages and disadvantages accruing to public utilities, or their competitors from recent advancement in the arts, or obsolescence in the facilities of either, when the services, or cost thereof, as performed by either is thereby affected.

Public utility valuations are made for various purposes. These valuations are used by various boards and commissions. For example, the Board of Equalization of the State of Montana is obliged to fix valuation of railroads within the State of Montana for taxation purposes. They have had several different methods suggested as to the proper way of arriving at such value and are giving earnest consideration to the suggestions for the purpose of determining which method is fair to the railroad companies as well as to the state.

In Montana the railroads pay an ad valorem tax. They do not pay, as in some states, a tax based upon their gross revenues within the state, but, in addition to the ad valorem tax they pay a corporation license tax of one per cent of their net proceeds derived from their business transacted in Montana.

The Supreme Court ruling in the O'Fallon case is another example of the use of public utility valuations.

The accompanying article by L. D. McPherson, a valuation counsel, presents a method of valuation of public utilities for taxation purposes.—Editor.

(d) Whether or not the state reserves to itself the exclusive power to tax the public utilities.

(e) The extent to which the valuation of property used in unregulated business as fixed for taxation varies from the fair market or service value of the same.

(f) The extent to which unequal taxes of public utilities affects the cost to them to finance expansions of facilities.

(g) The probabilities that

1. Rates of the public utilities for services are on an approximately permanent level;

2. Volume and classes of their business will continue substantially uniform for a few years.

(h) The honesty, economy and efficiency of the control and management of the public utility.

(i) Expediency, or economy of administration by taxing authorities (comparative cost of collection of the state's revenue at other sources). By preventing the undue shifting of the burdens of taxation from other property to public utilities, state taxing authorities will avoid usurping the duties and powers of state and federal authorities in regulating rates and services.

Ascertaining the financial results of operation of public utilities depends upon accounting and involves the whole responsibility of their control and management.

When the state's revenue is at stake no presumption will be indulged. It may be assumed that all reports, returns, records, vouchers or other documents made or kept by the public utility for its own information or required by law and regulations, state or federal, can by law be made available for, and admissible in, evidence in a hearing on taxation. With broad inquisitorial powers vested in public authorities, officially prescribed accounting for capital expenditures, operating and other receipts and disbursements may be so enforced as to reveal the financial results of operations. It is possible that a restatement of the accounts of public utilities may be required to determine whether or not the revenue has been so handled, for the accounting period adopted for making the valuation, that all changes in tangible property and the financial results of operation would be analyzed in such detail as to afford an accurate basis for a just determination of the profitableness or usefulness of the public utility.

The public utility property, or a distinct or separate unit thereof, for which honest, economical and efficient management can show no financial results of operation, which are beneficial to the owners thereof, should be taxed on no higher than a scrap or salvage value, plus the cost to the state, or its subordinate agencies, of whatever services there is required to be rendered it, including fire, police and other protection. If such public utility become so impressed with the nature of a communal facility, it would thereby be entitled to relief from taxation to this extent.

Apportionment.—If the entire public utility is correctly appraised, there remains the difficulty of apportioning the value of interstate public utilities to the several states served. Danger of duplication always exists because each state within its own realm is independent of every other state. The hardship of decisions which do not eliminate this chance of overlapping is not easily relieved by review, because no evidence will more than tend to prove the portion of the total due to an individual state.

In apportioning, judgment should be influenced by a fair consideration of, among other things, the relative importance, both within and without an individual state, of:

(a) Total units of service facilities involved, such as mileage, and classes thereof, of all lines of railway tracks, telephone, telegraph, transmission and trolley wires, pipes, sewers, conduits, aqueducts, toll roads, including the necessary appurtenances and accessories of each, such as:

1. Land for sites for all such facilties;

2. Substructures, superstructures and equipment of shops, engine houses, power houses, transformers, pumping and relay stations, tunnels, bridges, reservoirs, containers, elevators, warehouses, wharves, docks, office and other service buildings.

(b) The number of units of service performed, such as mileage, per ton, engine, train, truck, taxicab, van or omnibus, car, passenger, crew, loaded and empty movement; cubic feet of natural or artificial gases; kilowatt-hours of electricity; gallons of water, oil or other fluids; number of messages, local and long distance, direct and reverse charges on same, etc., including distances, elevations, curvature or other resistances involved.

(c) The extent to which the services performed by the public utility is monopolistic or is being dispensed with by potential patrons resorting to competing substitutes.

(d) Volume, density and classes, as well as the seasonableness or fluctuations therein of local, through and interline business originated, on, handled over or delivered by the various branches, separable units or trunk line facilities in the several states, the relation of each to the individual public utility's total business and the relative desirability to such public utility of all business transacted.

(d) Whether or not the lines or facilities are branches or auxiliaries, which are only capable of originating business requiring further processing of unfinished products or services for which intervening services by a trunk line are indispensable to the collection for services.

(f) Relation of the actual service demanded of and performed by the public utility to the capacity of the facilities which it must own or control.

(g) Climatic and seasonal disturbances which affect operation and maintenance.

(h) Operating ratios; revenue collected; expenses and damage claims paid.

(i) Fixed rentals paid for use of facilities in the several branches of the service and in the several states.

(j) The relative amount of reserves impressed with obligations for replacement, depreciation, amortization or other sinking funds applicable to the facilities owned or leased in the several states or different branches of the service.

(k) The nature and amount of the liens or other encumbrances, on the parts of the property in the several states or different branches of the service.

Property not used by public utility in the performance of its services to the public, but which is being held for investment or objects not directly connected with such service, should be valued separately from its operated property and taxed on the same basis as if owned or used in unregulated business.

If an easier way, which is just and equitable, can be found to value steam railways and other public utilities for purposes of taxation, it should be adopted.

Ground Water in Southern Idaho

An investigation to determine the geology and underground water resources of the Snake River lava plain, in southern Idaho, has been carried on since May, 1928, by the Geological Survey, Department of the Interior, in cooperation with the Idaho Bureau of Mines and Geology, Idaho Bureau of Reclamation, North Side Canal Co., Twin Falls Canal Co., Minidoka Irrigation District and Idaho Power Co., under the general direction of Harold T. Stearns. The region studied covers over 16,000 square miles. Maps have been prepared showing the direction of movement of the ground water under this vast plain, also the location of the wells from which the measurements were obtained. Many interesting conditions are shown by the ground-water contours — for example, near Idaho Falls, where the ground water is moving westward toward the heart of the desert instead of southward with the slope of the ground surface and the Snake River. These maps are now open for public inspection in the Geological Survey office at Room 232, Federal Building, Idaho Falls, Idaho.

Management and Operation of a Water Works System

General Outline of Methods of Operation at Ottawa, Ont.

By W. E. MacDONALD
Water Works Engineer, Ottawa, Canada

BY instituting a bureau of purchases and supplies it has been found possible to effect substantial savings in the purchase of material and supplies. Requisitions for goods from time to time are made to the purchasing officer in charge of this division and by planning the work, where possible, well in advance, purchases can be made in quantities and when advantage is taken of the low prices that prevail during certain periods when the manufacturers are over-stocked substantial savings may be effected, provided adequate and well located storage space has been arranged for.

Pumping Stations.—In recent years, many factors have largely been responsible in changing the trend of pumping practice. Probably one of the most important changes wrought has been the introduction of the centrifugal pump, which has become a serious competitor of the reciprocating steam engine driven type. The extended use of electricity has witnessed the installation of electrically driven centrifugal pumps as a moderate and convenient means of handling large and small quantities of water under almost every conceivable condition.

In Canada the difficulties of operation in winter through the formation of frazil ice have been greatly lessened by the use of revolving screens combined with the application of steam.

Distribution System.—The distribution system should be designed that it will be capable of supplying adequate quantities of water throughout the entire district for domestic and commercial purposes as well as for fire extinguishment. The cost of a distribution system is usually the largest expenditure of any water works and consequently great care must be taken in both the original design and the extensions as required from time to time.

The planning of a water works distribution system with respect to improvements looking to greater efficiency and more production, is a matter that must take into consideration not only immediate results, but also requirements of the future, when growth and extension of the municipality will call for greater facilities.

New Main Extensions.—In many cities throughout Canada the frost penetrates into the ground for a depth of from 4 to 10 ft. below the surface, necessitating installing mains in many cities west of Winnipeg, with a minimum covering of 11 ft., to prevent mains from freezing. It is important that the engineer should have definite knowledge in advance of the frost penetration in various grades of soil in his own municipality to permit of the mains being installed with a minimum of covering to safeguard freezing, yet avoiding an installation at too great a depth incurring an unnecessary cost.

In regard to the construction work carried out by the city of Ottawa in connection with new water main extensions, where a minimum average covering of 7 ft. is necessary, allow me to set forth the procedure that has been established. When it is proposed to make extensions the engineer in charge has a report prepared with estimates and detailed plans showing the cost of construction, the required revenue and the estimated revenue from the property served by the extension. The work having been duly authorized, the engineer then selects the most competent foreman, and issues an official work order, to which is attached a blue print setting out the new extension, giving the location of all valves, hydrants and specials. These work orders made out in triplicate, contain detailed instructions to the foreman and state definitely the amount of material he is permitted to requisition from the corporation stores. The effect of these orders is to only allow the foreman to receive from stores, the exact amount of material contained in the engineer's estimate and thereby tends to economy. Upon completion of the work, all material and labor is entered on the order and all changes and installations are indicated in red on the blue print and returned promptly by the foreman to the draughting office where a permanent record is made.

Unit Costs.—In addition, the department requires the foreman to make, each day, a complete report of the day's operations which include the following items: The cost of the work performed each day, complete cost to date, materials used each day, and a complete summary of work carried out to date. From these reports the department completes its records in detail, which are submitted to the engineer, and from which he is at once able to make an analysis of the unit costs of all foremen. The effect of these records greatly increases the efficiency of the foremen who soon realize that a permanent record is maintained of their work.

Care in Main Laying.—In the past there seems to have been a tendency to use less care in the construction of the distribution system than was exercised in the construction of any other part of the water works system. This may have been due to the fact that the work was soon covered and out of sight, or from previous lack of experience in good construction practice. Whatever the reason, it has resulted in the development of much trouble often occurring at the most inopportune times and resulting sometimes in heavy property damage and loss of life. Having a previous knowledge of all this the city of Ottawa is most careful in the installation of all mains and services. In this respect I might say that all cast iron pipe gate valves meters and special pipe castings are subject to a standard hydrostatic test before acceptance and must be certified as having satisfactorily met these requirements by one of the official inspection companies. In addition to this as a secondary precaution against the possibility of trouble developing later, the resident engineer is required to see that all pipes and fittings are properly in alignment in the trench, sufficient supports and necessary tie rods in place. When this condition is satisfactory, the pipe must be filled with water and the pressure raised to permit of an examination for any defects previous to allowing any backfilling of trench.

Protection from Frost.—In many Canadian municipalities owing to extreme cold weather conditions in service and main laying it is not always possible to secure sufficient depth of covering to prevent freezing. For example in the following types of construction, where pipes are suspended across rivers, supported on viaducts, intersect subways and tunnels, it is absolutely necessary, in order to secure protection from frost, to have all such pipes and fittings properly insulated.

Insulation.—During the past 15 years the city of Ottawa, like many other Canadian municipalities, has experienced considerable trouble through interruptions to its service with the resultant damage and monetary loss through the freezing and bursting of many large water pipes and valves. This trouble has invariably occurred

during the coldest winter weather, sometimes when the temperature has been as low as 30 degrees F. below zero. To prevent the re-occurrence of this experience the engineering department of our city now insists on that all water pipes, valves and fittings exposed to freezing temperature must be sufficiently insulated against cold to prevent damage by freezing.

Various forms of insulating experiments have been carried out by the department during the past few years but probably the best protection has been secured from the following method:

The pipe itself is wrapped with one layer of hair felt 1 in. in thickness and secured to the pipe with a wrapping of heavy jute twine at 2-in. centers. Over this is applied one layer of heavy asphalt saturated felt secured in place by the wrapping of jute twine. This process is repeated in its respective order until four complete wrappings have been made. On top of the fourth layer of hair felt is placed a close winding of special electric insulating tape to hermetically seal the joints, and when this is finished it is given a treatment of asphalt compound. The insulated pipe is then wrapped first with oiled paper and an additional lining of heavy rosin sized paper. To protect this insulating material against weather conditions the whole is finally enclosed in a jacket of 8 oz. canvas which is treated with a heavy coat of glue sizing and then with two coats of first quality white lead and linseed oil paint.

Maintenance of System.—There are few works which require greater care and more constant vigilance on the part of its employees than does the operation and maintenance of a public water supply. Under the operation and maintenance division there must be considered the following appurtenances: inspection and maintenance of fire hydrants, valves and meters, prevention of electrolysis, regular and systematic survey for the detection of leaks, thawing of frozen services and finally the efficient handling of all general and emergency repairs to the system throughout the 24 hours each day.

Fire Hydrants.—The proper functioning of fire hydrants in all municipalities is a factor which should receive utmost consideration from the authorities in charge. In this connection let me state that I do not consider it good business to pay out, annually, huge sums of money to maintain an efficient fire brigade unless the water works department is maintained on an equally high standard of efficiency.

In Canada particularly, it is necessary to see that fire hydrants are correctly installed to insure proper functioning in service at all times. In the installation of fire hydrants it is highly desirable to see that all lateral connections are equipped with special control valves and laid at a sufficient depth below the frost line to prevent freezing. The hydrants themselves should be plumbed, well set and provision made for drainage through the adjacent sewer. If the foregoing practice is rigidly followed it will be found that the trouble through freezing will be greatly minimized.

However, in many of the most northern Canadian cities, especially with regard to previous installations, it is necessary, during the freezing period that all fire hydrants be inspected at regular intervals. In Ottawa we find it necessary to examine all hydrants in the business area every 24 hours, while the hydrants in the residential sections are inspected every 48 hours. Perhaps one of the most efficient methods of ensuring that this hydrant inspection is properly carried out is to insist on the inspectors marking, in chalk, on the hydrant, the date of inspection and the letter "A" or "P," indicating morning or afternoon. When making the next inspection these chalk marks are effaced by the inspector and the new time and date again indicated in chalk.

Gate Valves.—One of the most important items and one which very often receives but slight attention, is the proper location and maintenance of gate valves. In the city of Ottawa at every opportunity and especially previous to laying of new pavements the department installs sufficient additional valves to decrease the sectional shut down so that at any time it will not be necessary to close down more than one city block. All gate valves are installed in chambers and are inspected at least annually, for the detection of gland leakage and to ascertain if they are in proper working order. At such times the stuffing boxes are packed, gearing lubricated and a test made to determine that the valve is fully open.

Meters.—The sale of water through meters has become now nearly a general practice, resulting naturally in a rapid increase in the number of meters in service, and requiring increased attention be given to their proper care and supervision.

In Canada to date the full benefit of the metered system is not fully apparent as few of the municipalities are 100 per cent metered. However, practically all of the Canadian cities have realized that the selling of water by measurement is the only equitable way and they are rapidly endeavoring to organize this important branch of the service on a proper basis with a view to increasing the number of metered services.

To successfully carry out a meter program in the city of Ottawa, we have built up an organization as a separate branch of the service whose duty it is to test, install, read, repair and systematically record the individual performance of all meters. The records established by this branch of the service have been of inestimable value to the officials of the department in properly administering its affairs in selecting and purchasing the highest quality of meter and in addition, allowing the superintendent to maintain an accurate check on all services so that the water works department is assured of all income justly due.

Electrolysis.—The city of Ottawa has not been greatly troubled by electrolysis owing to the fact that all returns from the street railway power lines have been grounded to the cast iron distributing header. The effect from this has greatly minimized the trouble from this source.

Detection and Prevention of Water Waste.—The problem of reducing the waste of water which invariably occurs in all unmetered cities and towns should receive an amount of attention, from engineers and water works officials, equal to that formerly given to the problem of securing additional supplies, when the demands for water bid fair to exceed the capacity of the source in service.

The three methods most effective in reducing wastes in the city of Ottawa have been as follows:

(a) Regular inspection.
(b) Waste water surveys.
(c) Installation of meters.

It has been found that a large percentage of the careless waste in buildings from defective plumbing and fixtures can be controlled by a systematic interior building inspection by competent and specially trained inspectors in uniform. The work of these inspectors is rigidly backed up by the department and all consumers must maintain the plumbing in a satisfactory condition, otherwise, failure to do so will result in the supply being temporarily discontinued.

In many Canadian cities, contrary to the prevailing practice found in the United States, it is quite common to have the peak consumption occur during the coldest winter months rather than in the warmest months of the summer season. This unusual condition is brought about by the consumers allowing the water to run to waste to prevent freezing. This condition of waste is not one which should be tolerated or accepted in any city as a solution of the cold weather problem of freezing. An effective method of overcoming this extravagant waste has resulted from the work of our uniform waste water inspectors covering the entire city during the cold weather period and reporting to the engineering office all consumers found running water to waste to prevent freezing. On the receipt of the information, the owners are informed by letter that this unnecessary waste of water must cease and that the pipes and fittings must be protected and insulated against cold. These notices usually allow the owner a period of time not exceeding six months to comply with this regulation. The efficacy of this work is well worth while, as demonstrated by the fact that during the past three years we have re-

duced our daily average winter consumption by more than 2,000,000 gal.

The determination of underground leaks and their ultimate repair is a work which occupies considerable time and in the larger cities is best handled by the organization of a separate pitometer branch of men specially trained in this work. As a great deal has already been written on pitometer operations I will not attempt to elaborate on them here, but will state that my personal experience has been that the results of these surveys is wholly dependent upon the initiative and the efficiency of the operator in charge.

Of all means for the reduction of waste there is none more beneficial for securing results than the introduction of high quality meters and all water departments are well advised in working towards a hundred per cent metered supply.

Thawing of Frozen Services.—Until a few years ago probably one of the most vexing questions confronting the officials of a Canadian water department during the winter months, was the freezing of service pipes. The city of Ottawa, during the extreme weather conditions, probably was affected with more frozen services than any other city on the Continent. There have been winters in Ottawa when services of more than three thousand consumers have been frozen and the department in years past was unable to cope with this situation with the result that many hundreds of families in previous years were without water for many weeks at a time. Like all other water works problems requiring action the city of Ottawa took hold of this situation in 1919 and discontinued thawing services by the former unsatisfactory transformer method and designed and constructed four self-contained electric thawing apparati. The success of these new machines has been truly marvelous in rendering a prompt and efficient public service as well as having reduced the cost of each thawing operation from $6.05 per service to $1.78 per service; effecting an individual saving of $4.27 per service. Allowing for all operating costs, interest and depreciation, the thawing machines have been directly responsible in effecting a saving, during the past few years, of $23,000.

I might say that the city of Ottawa has carried on a program of lowering and insulating where necessary, many services where continual trouble from freezing was experienced in the past and this work, together with the new machines, has done much to lighten the burden of the water department during the winter months.

Keeping the Finger on the Pulse of the System.—To definitely insure the service of the department being efficiently maintained at all times during the 24-hour period we have inaugurated in Ottawa, a central headquarters bureau. The purpose of this office is to co-ordinate all the various branches of the water department. At this office all complaints are received and the officer in charge is continuously informed of the working of the entire department, receiving hourly readings of gauges from the pumping stations, transformer stations, and filtration plant as well as pressure gauge readings from all city fire stations. This office is equipped with fire alarm gong, automatic pressure gauge and furnished with a complete set of plans and blue prints of the entire distribution system, giving exact location of all mains and valves.

Emergency Service. — Emergency service is a most important part of the water department's responsibility in safe-guarding the lives and property of the citizens, and the city of Ottawa has placed this service directly under the central headquarters office. To meet this situation we have specially trained employees operating two emergency trucks completely fitted with all supplies and appurtenances. As a means of assistance in controlling breaks within a minimum of time we have had erected at every intersection in the city valve location plates, giving definite information as to the size and location of each valve. These plates have been of great value, especially in the winter season when it is quite usual to have several feet of snow over many of the valve covers.

Confidence Through Publicity.—Municipal officials can make the work of their departments far more effective by taking the public into their confidence. This can best be accomplished by a judicious use of publicity through the daily press in both its editorial and advertising columns; by assuring the public of the safety of the supply; by the encouragement of the citizens to visit the water works plant; and by seeing that the visitors are made welcome, shown over the plant and intelligently advised as to its workings. At all times see that the public are well informed on the services you are performing, for even though you may consider your local organization ideal, the citizens will not consider it so unless you have the press support back of it.

Acknowledgment.—The foregoing is an abstract of a paper presented at the Toronto Convention of the American Water Works Association.

State Sanitary Engineers to Meet in Chicago.—The next meeting of the Conference of State Sanitary Engineers will be held in Chicago, Ill., on Oct. 13, 14 and 15, 1928, with headquarters at the Hotel Stevens. Arthur P. Miller, Butler Bldg., 3 B St., S. E. Washington, D. C., is secretary-treasurer.

London Water Supply

Notes on Chlorination, Prefiltration and Double Filtration

The 23rd annual report of Sir Alexander Houston, head of the water works of London, England, covering the year ended Dec. 31, 1928, is summarized in a recent issue of The Engineer, from which the notes following are taken:

Chlorination of Thames Water.—The period covered by the report is the 13th year during which Thames water has been dealt with by this process. Never since it was begun in 1916 has there been a single instance of complaint as regards taste, though some 76 million gallons are treated every day and some 2,000,000 consumers are each supplied with an average of 38 gal. per day each. Apart from a large saving in coal consumption, since pumping into reservoirs is to a considerable extent lessened, there has, since the introduction of chlorination, been a marked increase in the number of million gallons of water filtered per acre of filter beds cleaned. In the worst case—that of Kempton Park—the increase was from 28.1 to 31.47 millions, and in the best—at West Middlesex—from 35.25 to 67.40, a rise of 32.55. As it costs some £40 to clean an acre of filter bed, it will be realized that the saving that has been effected is very considerable.

During the year an up-to-date liquid chlorine plant, installed at Hampton, took the place of the last remaining chloride of lime plant for chlorination on the board's works. A new factor, too, was the utilization of raw Thames water from the Staines Aqueduct for filtration on the Southwark and Vauxhall filters at Hampton. The water was drawn from the aqueduct at the outlet to the Littleton Reservoir, and passed down the Littleton conduit to Hampton, a special chlorination plant being erected at the Littleton outlet to deal with it. The average dose applied, in terms of available chlorine, was 0.42 part per million. The average cost of chemicals per million gallons treated worked out at 8.8d.

Chlorination of the New River.—Normally, the New River is only chlorinated during the winter months when the water deteriorates considerably in quality, owing, chiefly, to floods, the deficiency of storage accommodation, and, to some extent, to the filtration area being hardly adequate in size. Hence, although the annual reports are now based on the calendar and not the financial year, it was considered advisable that the period covered by the report should be from November, 1927, to March, 1928. Sir Alexander reports that the results obtained were rather remarkable. One hundred and four samples collected at Highfield, before chlorination, contained B. coli in 1 c.c. —or less—in 68.3 per cent of the sam-

ples examined. The same number of samples collected at Wood Green, after chlorination, contained no B. coli in 100 c.c.—or one hundred times as much water—in 85.6 per cent of the samples examined. At the outlet from the Hornsey reservoir the results were practically the same, no B. coli were found in 100 c.c. in 84.6 per cent of the 104 samples. The main point is that the effects of the winter floods, as shown above Highfield, before chlorination, are practically effaced, in a bacteriological sense, by the chlorination process at that station, so that when the water reaches Wood Green it is literally transformed in quality."

It may be added that the total cost of the chemicals used in the New River treatment was £520.54, or at the rate of 1s. 10.8d per million gallons treated.

Pre-Filtration Waters.—Since 1922 all the various kinds of water which "feed" the filters, and which are known as pre-filtration waters—raw water, stored water, gravel water—have been completely and thoroughly examined, chemically and bacteriologically, each week. Sir Alexander remarks that he "feels that the pulse of the metropolitan water supply is the condition of the pre-filtration waters," and he derives some most interesting information from these examinations. For example, he finds that there is an enormous improvement in the bacteriological quality in the raw Thames, Lea, and New River waters, consequent on storage. As an instance, he points out that as raw Thames water contained B. coli in 57.7 per cent of the samples in 0.1 c.c. —or less—and as Chelsea stored water contained B. coli in 100 c.c. in 57.6 per cent of the samples, it might be said that Chelsea stored water was improved 1,000 times. Indeed, from the figures adduced, it is seen that nearly all pre-filtration waters are improved from 100 to 1,000 times as compared with the raw river water. Moreover, it is impossible to store river water without certain physical and chemical changes taking place, and it is possible to read into these alterations of composition, indirect, but valuable evidence of what has taken place bacteriologically. It takes time to effect these physical and chemical changes just as it requires time for the destruction of pathogenic bacteria in water under conditions of storage. From the figures in the tables given in the report, it is obvious that the raw waters are, generally speaking, altered considerably in character by reason of storage, and that the percentage reductions for the various tests are not uniform, the tendency being for the ammoniacal nitrogen, turbidity, and color tests—especially the first two—to show proportionately greater reductions than the albuminoid nitrogen and permanganate tests.

The Barn Elms Experiments.—What are known as the Barn Elms experiments were instituted some years ago to test the effects of passing water, which had previously been treated in primary filters, through an ordinary sand filter at rates up to three times the customary London rate, which is rather less than 2 gal. per square foot per hour. For the purpose, the outlet of one of the filter beds was altered so that this increased rate of flow could be obtained. The chief questions which it was sought to answer were:

(1) Would the filtrate from the altered bed compare favorably, or unfavorably, with the filtered waters generally, as judged physically, chemically, and bacteriologically?

(2) Would there be an increase, or a decrease, in the "number of million gallons filtered per acre cleaned?"

(3) Would there be any evidence of a gradual, but progressive blocking of the interior of the filter, resulting in "the number of gallons filtered per acre cleaned" becoming less and less as time went on?

An adverse verdict regarding No. (3) would mean that practically the whole bed would have to be turned over and cleaned periodically, as, indeed, is the custom at some works of the board. In such a case, everything would depend upon the extent of internal blocking as a result of the "rushing" filtration tactics. So far as the test has been carried, it does not appear, according to the report, that any progressive interior choking of the bed is foreshadowed. Furthermore, as the result of about 52 months' experience, it would seem that the following results can be obtained, assuming comparable conditions, by the methods employed at Barn Elms:

(1) A final product practically as good, on the average, as that resulting from the ordinary slow filtration process.

(2) Comparative freedom from algal troubles, or those caused by an excess of suspended matters, owing to the useful work carried out by the primary filters.

(3) A considerably greater output of water per acre of filtration area, allowing for the space covered by the primary rapid filters, per unit of time.

It may be added that the primary filters have been worked at an average of 141 gallons per square foot per hour, while the experimental filter has been worked at an average of 4.42 gallons per square foot per hour, and has yielded 75.1 per cent of first-class samples, i. e., no B. coli in 100 c.c. water.

Walton Works.—At the Walton works rapid filtration is followed by a filtration, at considerably more than the usual rate, through ordinary sand filters. Raw Thames water is first stored in Walton reservoirs, then filtered — without coagulant — through eighteen primary filters, working at the average rate of 112 gal. per square foot per hour. The next process is filtration through secondary filters working at the average rate of 5.61 gal. per square foot per hour. Finally, the water is chlorinated, the average dose being 0.207 part per million.

The results obtained, as set out in the report, are as follows:

Bacteriological (Average) Results

Number of Bacteria in Agar at 37 deg. C. per c.c.

A. Raw river water 275
B. Walton stored water 15
C. Mixed filtrates from one set of primary filters 18
D. Mixed filtrates from other set of primary filters 21

Filtrates from the Six Secondary Filters Before and After (in brackets) Chlorination

E. No. 1 Filter 2.8 (2.7)
F. No. 2 Filter 5.4 (4.3)
G. No. 3 Filter 3.3 (2.7)
H. No. 4 Filter 5.8 (4.3)
I. No. 5 Filter 3.4 (2.9)
J. No. 6 Filter 5.3 (4.9)
K. Final filtrate from the general filter well (mixture) of all the chlorinated waters 3.7

Percentage Number of Samples Containing No. B. Coli in 100 c.c. (First-class Samples)

The results are given in the same order as in the foregoing:

A. 0.0 (91.6 per cent contained B. coli in 1 c.c. or less).
B. 34.5.
C. 45.0.
D. 51.4.
E. 92.3 (99.1).
F. 89.9 (100.0).
G. 83.2 (98.1).
H. 89.1 (100.0).
I. 93.9 (99.1).
J. 76.3 (93.5).
K. 96.4.

It is explained that the results, as regards A, B, C, D, and K are for the calendar year 1928. The results for E to J are for the period Jan. 1 to Nov. 9 inclusive; afterwards the place of chlorination was altered to allow for the addition of ammonia before chlorination, the mixed water from all the filters being chlorinated at one spot, before going to the general well.

"Bacteriologically, it would be hard to surpass these results," remarks the report. "To change a water containing B. coli in 1 c.c. in 91.6 per cent to one yielding no B. coli in 100 c.c. in 96.4 per cent of the samples examined is a striking feat."

The report gives much further interesting information regarding these works, and the experiments made with the filters, as well as several further tables. We can, however, only spare space to quote the final paragraph in this section: "In looking through these results many items catch the eye; for example, the very high rate of filtration in the case of the primary filters (112 gal. per square foot per hour). The high rate of filtration through the secondary filters (5.61 gal. per square foot per hour), having regard to the much lower rates commonly employed. Finally, the remarkably high number of million gallons filtered per acre cleaned (576 m.g.)."

Equipment for Electrically Driven Pumping Stations

A Method of Improving Operation and Securing Economy at Low Cost

By R. L. BALDWIN

Of Burns & McDonnell Engineering Co., Kansas City, Mo., and Los Angeles, Calif.

MANY small cities have direct pressure systems for water supply. Where steam driven pumps are used it is possible to vary the speed in proportion to the quantity of water required thereby maintaining an even pressure.

Where motor-driven units are in use it is difficult to maintain constant pressure since the motor speed of standard equipment is constant. This means that pressure must vary with the discharge and that unfortunately when more pressure is required at high rates of discharge to compensate for friction losses, it is low or inadequate. Such installations are, therefore handicapped with poor pressure regulation. High pressures must be carried at times when not needed in order to have an adequate pressure when large capacity is required. This in turn causes poor over-all efficiency, often being from 30 per cent to 40 per cent, and even less.

Where it is possible the installation of elevated storage on the system solves this question and adds many other advantages. At the outset, the writer wishes it understood that the method of operation proposed in this paper is not a substitute for elevated storage, but that it does give a method of improving operation and economy at low cost and may serve in many cases where the use of elevated storage is not feasible. The paper is an application of the automatic method of operation to the pumping of water with particular attention being paid to improvement of economy.

The Motors.—The use of a variable speed motor may serve in some instances to drive a pumping unit and obtain reasonable efficiency. If a slip-ring motor is used, resistance must be used to obtain reduced speed. Ordinary operation must be at the reduced speed in order to have increased capacity at higher speed for peak demands. This means a high energy loss in the resistors in order to obtain this speed control and a corresponding low efficiency.

A motor of the brush shifting type offers good efficiency at all speeds but it has serious speed limitations. The manufacturers have not encouraged its use for such service. Up to this time such a system has not been found economically feasible.

The use of pole changing devices for the variation of motor speed for this purpose causes too great a change in speed at each change. It has been used in some installations but is not generally suitable for a direct pressure system.

Boosters.—Boosters are often used where an increase in prassure is desired for short periods. In the ordinary system it is desired to maintain a satisfactory pressure on the distribution system. Very often a transmission main is required to convey the water from the pumping station to the distribution system and this involves high friction losses at times of maximum discharge. Boosters when used are usually designed for a fixed discharge and pressure to care for the maximum discharge and pressure desired.

Fig. 1—Layout of Assumed Pumping Station

Another method might be used, namely, two or three ordinary centrifugal pumps driven by constant speed motors with a booster of variable capacity and pressure designed to take care of friction losses. In this way the base load pumps could be operated at a maximum efficiency and the low efficiency would be on the booster pump alone. At low rates of discharge necessitating low speeds, the efficiency of the booster would be low but it would carry only a small portion of the load and hence would not affect the overall efficiency much. At the high rate of discharge when the friction is increased and becomes a larger portion of the total load, then the higher speeds are required and the overall efficiency is better.

Assumptions.—In order to determine the overall economy of pumping with such an arrangement, a case has been assumed where it is desired to maintain a pressure on the distribution system of approximately 160 ft. head and not less than 140 ft. head. The friction loss between the pump station and the center of the distribution system has been assumed to vary from zero at no load to 100 ft. head at the maximum rate of discharge.

Operation on the flat portion of the head capacity curve for a centrifugal pump means fairly constant pressure, but the range of constant pressure operation with a single pump and with reasonable efficiency is very limited. Hence it is wise to use at least three units as they may be suited to the load more closely. An average pumpage of between 2 and 3 M.G.D. is assumed and standard single stage centrifugal pumps designed for heads and capacities as follow are used:

Pump No. 1—1 M.G.D. at 160-ft. head,	50 hp.,	1,800 r.p.m.	motor
Pump No. 2—2 M.G.D. at 175-ft. head,	75 hp.,	1,800 r.p.m.	motor
Pump No. 3—3 M.G.D. at 160-ft. head,	100 hp.,	1,800 r.p.m.	motor

The second is designed for a slightly higher head to take care of friction losses as it is desired not to connect the booster until more capacity is needed. The booster can use a standard centrifugal pump driven by a wound rotor motor of 125 hp. capacity, 1,200 r.p.m. With the friction losses at various rates of discharge known a pump can be selected so that it can be operated to exactly absorb the friction losses by varying the speed of the motor as required.

All of these pumps and motors are standard pieces of apparatus and their operating economy can be readily obtained at various loads and speeds. Reference to Fig. 1 shows diagrammatically the assumed layout. Figure 2 shows curves giving the characteristics of the booster pump at different speeds. These same data for the constant speed pumps are given in Fig. 3.

Method of Control.—By proper selec-

5.9	2-3	74.0	140.0	70.0
5.9	1-2-3	78.0	165.0	70.0
6.0	1-2-3	78.3	172.0	72.3

tion of the head capacity characteristics of the two small centrifugal pumps the pressure at the center of distribution may be maintained within reasonable limits without the expedient of the variable speed unit. These two units may be brought into operation or taken out of operation as may be desired by means of a pressure regulator type of control—pump No. 1 being cut out of operation when pump No. 2 is started. For this combination of pumps the rates of discharge at which pumps are started are shown in Fig. 3. The minimum pressure desired at the center of distribution determines the rate of discharge at which each pump is put into service. In this case a new pump of greater capacity is started when the pressure maintained at the center of distribution drops to 140 ft. head.

The variable speed unit will be put into operation when pump No. 3 is unable to keep the pressure above the minimum desired, and will operate at all higher discharge rates. Its speed can be varied by variation of the resistance in its secondary circuit using a motor-driven rheostat, the control being somewhat similar to that used for control of field rheostats on large generators to maintain a constant voltage.

Pilot wires can be used to connect the pump station to the center of distribution so that the entire control can be operated by that means. The loss of head through the metering device can also be used if desired as it is proportionate to the discharge, however, due to the variations in friction losses due to variations in the point of use in the distribution system, the method of using the pressure at the center of the distribution for control is preferred.

Calculation of Efficiency of Operation.—The efficiency for any discharge up to the rate at which the booster is cut into operation can be easily obtained from the ordinary data obtainable for both pumps and motors. When the booster is in service, the losses in the rheostat must be added to the losses in the motor. In order to make this study of efficiencies, an operating scheme must be set up for the different pumping units. Table I shows the pumps operating for various rates of discharge desired, with the efficiencies for the pump operating or the combined efficiency if two or more pumps are operating, the water horsepower developed and the total losses expressed in horsepower.

Table II shows the operating data for the variable speed unit. It gives the speed for different rates of discharge, the water horsepower, the power input and the total losses expressed in horsepower.

The total overall efficiency of the pumping installation is defined here as the ratio of the total water horsepower to the total power used by the motors including all resistance losses. The

4.6	830	47.8	58.3	38.1
5.2	1,000	68.0	82.0	34.0
5.6	1,060	84.5	101.0	29.5
5.9	1,130	99.9	119.0	29.1
6.0	1,150	105.0	125.0	29.0

following Table III gives the total water horsepower which is the sum of columns designated as W-1 and W-2 in Tables I and II. The column marked total losses is the sum of the losses for the constant speed pump and the variable speed pump given in Tables I and II under columns designated as L-1 and L-2.

The water horsepower plus the losses gives the total power required for eacn rate of discharge and from these data the overall efficiency is calculated and is tabulated in the last column in Table III below.

Conclusions.—Possibly better economy could have been obtained at some points by making some slight changes in the pumps selected for this particular case. However, the results obtained from this study are such an improvement over the ordinary direct pressure centrifugal pumping installation that it deserves full consideration where there are limited funds available for improvements.

If it is necessary in some cases to operate centrifugal pumping stations on a direct pressure system with the resulting low economy usually obtained it certainly behooves engineers and waterworks operators to seek some method of improving the conditions. The efficiency indicated here is approximately 65 per cent overall while present operation of direct pressure motor-driven stations is approximately one-half this.

The automatic feature of operation is saving in labor, but above all else it insures that the right pump is operating to obtain the best economy. Where the control is manual, pumps will not be started and stopped at the correct time. Less disturbance to electric and water systems is caused by automatic starting and stopping because it is done in the proper manner and at the correct time.

Breaking Up Mud Holes in a Filter

BY A. L. GOSNELL
Filtration Plant Operator, Laurel, Md.

In a recent discussion a question was asked about using a hose nozzle to break up mud balls in a filter. This same question was asked several months ago at the North Carolina section, A. W. W. A. It was this question that caused me to make the implement that I wish to explain in this article. Instead of a hose nozzle, use a piece of 1 in. pipe about 7 ft. long. Screw a cap on lower end of pipe, and put a 1 in. valve about 1 ft. from upper end. Drill nine ¼ in. holes in this pipe just above the cap, beginning 2 in. above the cap. Space holes 2 in. apart and make three rows with three holes in a row, divided equidistant around the pipe. This completes the nozzle end. It may be well to make the nozzle out of a short piece of pipe, so that in case you wanted to make a change, you could take it out and replace it with another. Attach a 1¼ or 1½ in. hose from this pipe to the high pressure water line. When ready to wash a filter, place a piece of 2 in. plank across the wash troughs to stand on. Start up wash pump, open up high pressure line through 1½ in. hose to nozzle, stand on the plank and push nozzle down through mud pockets while wash pump is running. The nozzle will break up the mud balls and the wash pump will bring them to the surface. It may be necessary to scrape the filter after this is done. Care must be taken to cap the lower or nozzle end of this pipe tight, as otherwise you might disturb the gravel bed. All streams from this nozzle must come out through the sides and not through the bottom. If conditions are such that the wash pump could not be run at full capacity for 5 or 10 minutes, or if there is a considerable amount of mud balls to be removed, open the wash valve about one-quarter way, and work on mud pockets 5 or 10 minutes. Cut out nozzle and open wash valve wide. The wash pump should run at its maximum capacity 3 or 4 minutes after nozzle is cut out. We have been using this home made implement about three weeks and find that it does good work.

Water Company Employes to Wear Uniforms

All employes of the Hackensack Water Co., Weehawken, N. J., whose duties require them to enter homes of consumers will hereafter be uniformed, it is announced by the president of the company, Nicholas S. Hill, Jr.

Inspectors, meter readers, and collectors will be attired in dark gray whipcord with the insignia "H. W. C.," in red, on the right breast, and will wear caps bearing the letters "H. W. C.," also in red.

The purpose of the uniforms, Mr. Hill explained, is to enable customers to identify Water Company employes, and to guard against unwarranted intrusion of homes by imposters who in the past have not infrequently posed as representatives of the company.

In deciding to adopt uniforms, the company acted upon the unanimous recommendation of its departmental heads.

Aggregates for Sewage Disposal Plants

Characteristics and Behavior in Practice of Three Materials

By HERBERT F. KRIEGE
In Charge of Tests, France Stone Co. Laboratories, Toledo, O.

WITH the increase in population about many centers the welfare of the growing communities depends upon the proper control of sanitation and hence to a great extent on effective sewage disposal. The types of disposal systems most widely used in this country are those employing contact and trickling filter beds. In both of these types, mineral aggregates are used as media for the beds. It is the purpose of this paper to discuss the characteristics and behavior of the various materials utilized in this connection in terms of conditions imposed upon them by usage.

The earlier types of sewage disposal systems, other than mere dilution in large streams or bodies of water, consisted of areas of sand or other small material over which the sewage was allowed to flow intermittently, thus exposing it to greater oxidizing and bacterial activities than it received upon slight dilution. As the quantity of sewage increased, the contact process was improved so as to consist of a well-defined area provided with good under-drainage and containing a mass of grosser mineral particles such as broken stone, slag, gravel, cinders, etc. The system as now used permits the slow filling of this contact bed with sewage which has previously had its heavier solids settled out, the sewage remaining in contact with the medium of the bed for a period of time, after which it is allowed to drain away through the under-drainage system. During this time of contact, a certain degree of stability has been reached through the partial oxidation of the organic substances contained in the sewage by the bacterial colonies lodged on the surfaces of the medium.

The contact method, though by no means discontinued, is giving way to the trickle filter bed system. This consists of an enclosed bed of aggregate, usually stone or slag, over which the sewage, after settling or treatment in the Imhoff tanks, etc., is sprinkled by means of sprays or traveling distributors. The sewage thereby receives some aëration before it comes in contact with the bacterial life on the medium. At all times in a properly functioning trickle filter bed, the large voidage provides for sufficient aëration to keep the bacterial colonies and sewage supplied with the oxygen demanded in the biochemical processes. During the time interval required by the sewage to trickle down the aggregate mass to the under-drain, a sufficient stability has been effected in the sewage to permit its passage directly into even small streams without creating a nuisance. The capacity of the trickle filter system is quite large, and hence this serves in congested areas as a satisfactory and efficient sewage disposal method.

Trickling Filter Systems—The distribution of the trickle filter systems through the United States is rather wide. According to the 1927 Progress Report to the American Society of Civil Engineers the Filtering Materials Committee of the Sanitary Engineering Division found that in 19 states east of the Mississippi River a total of 142 plants were in use serving a population of 2,800,000. West of the Mississippi River, nine states reported a total of 246 plants serving a population of 1,240,000, making a combined total of 388 plants serving 4,040,000 people in the 28 states reporting prior to April, 1927. Since that time a survey by the author has added 97 plants, serving an additional population of 754,950, making a total reported up to April, 1929, of 485 plants in 34 states. The distribution of these plants is stated more specifically in Table I.

Table I.—Installations of Sewage Filter Plants Reported with Approximated Population Data

States East of the Mississippi River

State	All Plants Reported Number	Approximate Population
Alabama*	1	80,000
Connecticut*	1	6,000
Delaware	2	4,100
Georgia*	4	385,000
Illinois	34	453,200

Oregon	1	10,000
South Dakota*	9	54,700
Texas*	122	718,000
Total west of Mississippi River	284	1,562,900
Grand Total	485	4,794,950

*Data taken from the April, 1927, Progress Report of the Committee on Filtering Materials, Sanitary Engineering Division of the American Society of Civil Engineers.

The volume of mineral aggregate entering into the trickle filter beds in the states reported amounts to 1,500,000 cu. yds. Therefore, these sewage disposal systems constitute a considerable market for aggregates, especially since the materials used are combined within rather close limits to one size.

Types of Aggregates—The aggregates which have come into most general use in both contact and trickle filter beds are broken stone, including both sedimentary and igneous rocks, blast-furnace slag and occasionally gravel, cinders, broken tile, broken retorts, etc. This variety in types of aggregate has been brought about by the desire to find some medium which would give a large effective surface for lodgment of bacterial life and yet would be an economically possible material. Experience has shown that certain of these aggregates are distinctly superior to others as to durability and general effectiveness.

In considering the requirements which the medium in a trickle or contact bed must meet, the conditions imposed by such usage need discussion. In practice the medium is intermittently wetted with the sewage and allowed to drain. This facilitates any disintegration or attack which hydration and oxidation under moist conditions might bring to pass. The action becomes particularly severe when during the winter months the aggregate is repeatedly frozen while wet and thawed by subsequent applications of the warmer sewage. In the trickle bed a dosing period of three to six minutes followed by a rest period of ten or fifteen minutes is not uncommon. This means that in twenty-four hours the filter bed medium may be alternately frozen and thawed nearly one hundred times, provided the temperature of the air is well below freezing. This becomes perhaps the most severe test which mineral aggregate is called upon to withstand in industrial practice. The properties of mineral aggregates which will enable them to withstand these conditions of intensive weathering will be considered separately.

The rapid growth in all lines of highway and building construction has required a more rigid classification of materials suitable for the work. The characteristics most commonly specified

and tested for in mineral aggregates are hardness, toughness, abrasion, absorption, weight per cubic foot and soundness. It is quite natural, then, that the group of engineers interested in sewage disposal practice should call upon these same specifications and test procedures to determine the suitability of media in sewage treatment. Some questions may be raised, however, as to the advisability of this plan since it may lead to a false conception of what constitutes the best material for this specific purpose. It is perhaps advisable that as much thought be given color, uniformity, crystallinity, fracture, cleavage, and the screen analysis with the percentage of voids of aggregates in the selection of the material. Roughness has been discussed though without any definite recommendations being made since no easy measure for the degree of roughness has been reported.

Hardness.—The hardness as commonly determined for aggregates is the resistance to wear or abrasion under standard conditions as prescribed in the procedure for the Dorry hardness test. The occasions on which either contact or trickle filter media are called upon in practice to show resistance to wear are few, about the only movement which the material passes through being that involved in the placing of the material in the bed. Hardness is no criterion of the durability of aggregates, particularly in the sedimentary stones which find quite general use in sewage disposal work. One of the hardest of the common minerals associated with the limestone deposits of this country is the practically pure silica mineral known as chert. This has a hardness approximating that of quartz, yet one form of it is a readily disintegrating material upon exposure to weather or sewage treatment. Likewise the hardest limestones are very often the ones that show the greatest tendency toward disintegration when exposed. This applies equally well to gravels composed largely of limestone particles. In the case of blast-furnace slag, which may be either dense, medium dense or honeycombed, the dense variety is naturally the hardest and yet this is more apt to show splitting either in actual or in experimental freezing and thawing or in the sodium sulfate test than is the medium dense or the honeycombed slag.

Toughness.—Since toughness is taken as the measure of the resistance of the material to impact, the same conditions referred to for hardness may be applied in this case. Practically the only impact which the material receives is during the placing. Aggregate of but moderate toughness can easily withstand that amount of impact. Likewise aggregates of great toughness often do not show any greater resistance to the disintegrating action of wetting and drying, freezing and thawing, than do those of lower resistance to impact. It does not seem advisable therefore to discriminate against an aggregate of lower toughness value for this reason only.

Abrasion.—The resistance to wear of one piece of aggregate against others and against the walls of the containing vessel is sought for in the standard abrasion test. This characteristic is somewhat allied to hardness and toughness and what applies to them applies also to abrasion. Argillaceous limestone and some chert may be mentioned in this connection since their abrasion losses are very low, yet their suitability for filter bed use may be very seriously questioned.

Absorption or Porosity.—Density in the mineral aggregates entering contact and trickle filter beds has been sought for quite generally, on the supposition that material which absorbs the least water or has the lowest pore space will be the one longest surviving the disintegrating action of freezing while wet. Woolf[1] has recently shown that when all types of naturally occurring aggregates are considered, igneous and sedimentary stones being included, the resistance to disintegration by five sodium sulfate immersions is somewhat in relation to the density of the stone. Unpublished data secured in the laboratory of the France Stone Co. show that this does not hold true when applied to limestones and dolomites and their associated minerals, particularly when the sodium sulfate test is carried to twenty cycles. The relation between the soundness as determined by these tests and the absorption on several hundred samples of such materials is highly irregular.

Weight per Cubic Foot.—From an economic standpoint at least, the weight per cubic foot has some bearing on the use of a certain medium. The purpose of the medium is simply to provide a sufficiently large surface on which the bacterial life may lodge to effectively alter the sewage in contact with it. Hence, the smaller weight of material used to provide this surface, the lower will be the cost, other things being equal. In this way one aggregate of lower density or higher porosity, even though it shows a higher abrasion loss, lower toughness and lower hardness, may be the proper one to use. Since a difference in weight of 500 lb. per cubic yard is not unusual between moderately porous limestones and dense trap rocks or gravel consisting largely of igneous material, it can easily be recognized that the unit weight is a definite factor in the economics involved. On comparing a honeycombed slag with the dense stone, the difference will be even greater.

Color.—While it may appear that color has little if any bearing on the characterization of the material for its use in sewage disposal practice, certain observations which may be made by visual inspection will prove helpful in the selection of the right material. Color is often an index to the chemical composition or the presence of certain minor constituents which may have a bearing on the general properties of the material. Usually the yellows, reds and browns indicate that the material has already been subjected to oxidizing conditions, while the blues, greys and blacks denote the presence of unoxidized substances such as carbon or iron compounds. Material already in the oxidized state may be expected to undergo less change upon further exposure than one in which this oxidation has not yet occurred. The presence of small amounts of silt, clay, beidellite and organic films can be detected more easily by color or luster differences than by any other simple means. In the case of limestones in the central states, some strata having a dull lusterless ash-gray color on fresh fracture may be regarded with suspicion, regardless of their other physical and chemical properties, since usually they show very little resistance to weathering action.

Uniformity.—The lack of uniformity in composition, kind of material, structure, and texture may be taken as an evidence of lessened resistance to the action of weathering. In the freezing-and-thawing experiments or other accelerated weathering tests the first evidences of the disintegrating tendencies seem to occur at points of non-uniformity in the material. Laminations, sutures, imbedded accessory crystals or masses, and inclusions, be they of microscopic or macroscopic size, appear to be the weakest portions of the defense against disintegration of the material. Blast-furnace slag which has every reason to be uniform in composition is a good example of how this uniformity beneficially affects resistance to freezing and weathering in general. These remarks should not be construed to mean that any material which is uniform is necessarily stable and resistant to disintegrating forces. Lack of uniformity however must be given due consideration when characterizing a material for use in exposed conditions. Reference should be made again to some chert whose tendency to disintegrate is so pronounced while its most closely allied mineral, namely, flint, is a common synonym for durability. In a recently published article by the author[2] the instability of disintegrating chert is attributed more to lack of uniformity in mineral structure and to enclosed

Table II—Relation of Type of Medium to Trickle Bed Clogging Tendency

Material	Number of Plants Reporting	Average Total Years of Service	Percentage Showing Clogging
Limestone	51	8	48
Granite, trap	29	7	23
Blast-furnace slag	11	8	18
Gravel	8	6	50

crystallin foreign masses than to any other observed property.

Crystallinity.—Whether a material is holocrystallin, grossly or finely crystallin, crypto-crystallin or amorphous does not seem to have any great bearing upon its behavior in trickle or contact bed use. However, when within a single piece of aggregate the crystallinity changes definitely, such as a zone of gross crystals within a finely crystallin or amorphous mass, or an amorphous clayey seam within a well crystallized mass, such structures encourage disintegration at that point. Since in the preparation of crushed mineral aggregates for the market the weakness of such structures are usually found by the fracture stresses during the crushing operation, not many of these weak planes persist in the finished pieces.

Fracture and Cleavage.—The fracture and cleavage habits of the commercially prepared products have some bearing on their fitness as filter media. The tendency toward slabby pieces is undesirable since this tends to produce a low voidage in the resultant bed due to overlapping of these slabby pieces in layers like shingles of a roof. Those fracture habits which leave the prepared aggregate with angular shapes and irregular surfaces are most desirable. In this property, slag, trap rock, and granite are most commonly in the desired class. Sedimentary stones free from shaley or slatey material likewise fall into this category.

Roughness.—Since roughness largely determines the amount of surface which a piece of aggregate offers, this property should be taken into account in the selection of a medium for purposes utilizing its surfaces. Experiments conducted at Philadelphia[1] to show the relative efficiencies of aggregates varying widely in their shape and roughness brought out the fact that the rougher the material the more efficient it was in the oxidation and stabilization of the sewage influent. The extremes of roughness in materials available commercially are well rounded gravel on the one hand and honeycombed slag on the other. The opinion has been expressed by some sanitary engineers that slag offers too great a roughness, that this roughness tends to hold the bacterial colonies and collected solids too long so that clogging of the bed is produced. The Progress Report of the Committee on Filtering Materials[2] contains some data pertaining to the effect of type of medium on the clogging tendencies. These have been rearranged in tabular form shown in Table II.

It appears, therefore, from actual experience gained with trickle beds operated in widely separated districts that clogging is not so common with highly irregular and rough surfaced material like slag as with the smooth, rounded gravel.

In February, 1929, the author saw the larger of these slag beds reported in the table above as having clogged. At the time of inspection (during a rest period) it was entirely clean, practically the only evidence that it was not freshly placed slag being a general iron stain covering the surfaces of the slag pieces in the zone of the sprays. This stain was apparently due to the iron compounds contained in the influent. A rest period of several months had completely relieved this bed of its clogging material even though it had been heavily overloaded for twelve years with an industrial and domestic sewage which was difficult to treat. Mr. C. C. Hommon,[3] in charge of the Canton sewage disposal plant, after examining all the known trickle beds using blast-furnace slag in the filtering medium, reported 29 on which no clogging had occurred, while 12 showed clogging or clogging tendencies. However, the tendency to clog in the latter cases could be explained in every instance (1) by poor sizing of the material placed in the bed; (2) by excessive loading without rest periods, or (3) by the poor condition of the influent. On the other hand, perhaps the largest gravel bed now in use was observed by the author during February, 1929, and found to be in a very dirty condition, indicating that this may occur even on a bed composed of smooth rounded pieces. Clogging of trickle beds is therefore due to some factor other than the roughness of the surface of the medium.

Little has been definitely learned about the relative roughness of different filtering media. In order to arrive at some fair understanding of this property in limestones known to be different in their fracture and cleavage habits, the following tests were conducted in the France Stone Co. laboratories. It had been previously shown that the fracture habits of limestone persist into the smaller sizes when the stone is crushed. In this way it is possible to study the roughness of any convenient size of material, say of No. 4 to No. 6 sieve size, and use that as a standard for either the larger or the smaller fragments.

The procedure consisted of determining the amount of material dissolved in dilute hydrochloric acid under controlled conditions of temperature, acidity, agitation and time, from a known area of polished surface of the limestone sample. This gave the specific solubility rate for that kind of material per unit surface. This same weight of material of No. 4 to No. 6 size was run under identical conditions. Since solution takes place only at the surface of the dissolving substances, the different amounts dissolved from the polished and the naturally rough pieces were in relation to the differences of the surfaces exposed or in other words, to the roughness. By comparing the amount of material dissolved from a given weight of the stone particles with the amount that would have dissolved had these particles been true spheres, a numerical ratio of roughness (including both shape and surface irregularities) was obtained. Some of the values found in this investigation are given in Table III, to indicate how widely the degree of roughness may vary even within the same class of material, in this case dolomitic limestone.

Table III—Relative Roughness Value of Some Dolomitic Limestones
(Based on a spherical surface as unity)

	Description	Roughness Value
Limestone A	Almost cubical shape with smooth surfaces	1.39
Limestone B	Fairly cubical shape with smooth surfaces	1.60
Limestone C	Fairly cubical shape with rougher surfaces	1.84
Limestone D	Fairly cubical shape with rougher surfaces	1.87
Limestone E	Irregular fracture, angular shape and fairly smooth surfaces	2.01
Limestone F	Irregular fracture, angular shape and irregular surfaces	3.01
Limestone G	Irregular fracture, angular shape and irregular surfaces	3.10

The method is not applicable to slags and other silicates.

Soundness.—Since the characteristic which most largely determines the usefulness of an aggregate for filter bed use is its ability to resist breaking down under the actions and forces imposed by service, several laboratory methods for predicting the behavior of materials in use have been developed. The more successful ones consist of (1) actual freezing and thawing at relatively short intervals and (2) a drying and soaking process in solutions such as sodium sulphate and sodium chloride in which the destructive effect of the crystal growth of the solution contained in the pores of immersed material is used as a measure of its resistance to actual freezing conditions. A more satisfactory method of testing, where time permits, is to expose the material in question upon the surface of some trickle bed in operation and to observe its behavior through a period sufficiently long to warrant conclusions being drawn. This method is being used by several sanitary engineers and aggregate producers.

From a laboratory standpoint, the sodium sulphate test for soundness is perhaps the most acceptable since it involves but little apparatus, labor, or space and results can be obtained within several weeks. An attempt has recently been made by the Committee on Filtering Materials of the A. S. C. E. to standardize the procedure for this test sufficiently to permit the same type of behavior to be found with a material sent to different laboratories for testing. While the results of this work have not

[2]Loc. cit.
[3]Unpublished report to the National Slag Assn.

yet been made public, it is believed that such an effort is well worth while and that it will show that no consequential variations result if the several laboratories observe the outlined procedure with fair accuracy. The procedure as followed in the France Stone Co. laboratories consists of immersing the samples, which have been dried for four hours at 105° C., in a solution of sodium sulphate which has previously been saturated at 30 to 35° C. and allowed to cool to room temperature. One cycle consists of 20 hours' immersion and 4 hours' drying, the specimens being examined immediately after removal from solution for any signs of disintegration, checking, flaking, cracking, etc. The number of cycles is usually 20, this number having been arbitrarily set as indicating a sufficient degree of resistance to expect long life in actual practice.

The materials which show distress early in the sodium sulphate test are (1) shales, (2) slatey material, (3) stone with carbon seams, (4) limestones with high non-carbonate content and (5) limestones containing chert of the kind which tends to disintegrate. Usually the destruction of these occurs before ten cycles are run, often before the fifth cycle. Blast-furnace slag, granite, trap rock and other igneous materials are noteworthy in their ability to resist the sodium sulphate test. Likewise these same materials show little disintegration in use in the filter beds. Limestones with their wider range in composition, structure and association show all ranges of resistance to this test and to actual weathering.

Types of Disintegration.—There is considerable confusion as to what types of disintegration are most serious to the effective service of the filtering medium. Some fear the crumbling type of disintegration, others the splitting into slabby pieces. Obviously that type of disintegration which provides material either (1) large enough to cause void reduction within the mass of the bed or (2) small enough to be retained by the organic matter near the surface of the bed would tend to lower the efficiency of the filtering medium. In order to describe more fully the types of disintegration which may occur in stone samples, the following key is given, which has been used in recording all the varieties of distress noted in the author's soundness tests. The amounts of material broken off during all of these forms of failing are indicated in grams.

A.....Horizontal split into 2 pieces.
A3, 4.....Horizontal split into more pieces.
B.....Vertical split into 2 pieces.
B3, 4.....Vertical split into more pieces.
H.....Horizontal chips from 1 piece.
H2, 3.....Horizontal chips from 2 or 3 pieces.
V.....Vertical chips from 1 piece.
V2, 3.....Vertical chips from 2 or 3 pieces.
Ban.....Banding failure.
C.....Imminent checking and splitting.
Ch.....Failure around cherty inclusions and limestone contact.
Chv.....Failure across cherty inclusions and limestone contact.
Cr.....Failure of crystals at contact.
D.....Complete disintegration by crumbling, etc.
D1, 2.....Number of pieces showing complete disintegration by crumbling, etc.
F.....Flaking—scaling on any side, horizontal or vertical.
I.....Infilling crumbling.
L.....Laminations failing.
R.....Broken pieces retained in the series to observe further breaking action.
S.....Surface solution effect.
Sc.....Scaling at surface.
Sh.....Shale failing.
Su.....Sutures failing.
OK.....Passed through individual test successfully.

Considerable work has been done by Orton,[1] Staley,[2] Withey,[3] Schlick[4] and other investigators with mineral aggregates and other non-metallic structural materials to find the relationship between the effects of freezing and thawing, either in the natural or the accelerated state, and the laboratory results of sodium sulphate, sodium chloride, magnesium sulphate, alkali and boiling and drying tests. No fixed relationship has been observed, however, the values of one sulphate cycle ranging from less than one to nearly one hundred freezing cycles with different types of materials or conditions of testing. Perhaps the most logical method is that suggested by G. B. Gascoigne,[5] in which the behavior of an untried material is predicted from the comparison of its

accelerated weathering resistance with that of a material known to be satisfactory both in test and service. Nevertheless it is becoming more evident as our experience with filter media increases that a material which will withstand 20 cycles of the sodium sulphate test as is most widely followed today,[1] can be expected to stand up well for several decades under the severe conditions imposed by actual service in trickle beds.

The factors directly affecting soundness of natural mineral aggregates of sedimentary origin are lack of chemical or physical uniformity within the specimen, more specifically existence of certain associated minerals such as shale, pyrite and some cherts, and the presence of considerable amounts of clayey material, beidellite, and similar hydrous alumino-silicates. The usually considered physical properties of hardness, toughness, abrasion, etc., play but minor parts in determining the life of filter material, as was pointed out in the discussion previous. The disintegration of granites and other igneous materials is so slow that the development of their factors of degradation is unnecessary in this connection.

Sometimes one finds a tendency to specify the chemical composition or some physical property for blast-furnace slag if it is to be considered for sewage disposal bed purposes. Such conditions as low lime, low sulfur, or low iron content are called for, with some thought being given to the density of the material. Slag, by the very reason of its existence, is made to conform to a definite chemical composition within narrow limits. It does not therefore seem the part of wisdom to arbitrarily set standards for slag if its use in a special field like sewage disposal is being considered. Rather it should be taken as it is if tests and use have demonstrated its suitability for that service. In Table IV are found data secured by Fred Hubbard of the Standard Slag Co., Youngstown, Ohio, on slags that were collected by C. C. Hommon from trickle and contact beds in service. It should be observed how little variation there is in these slag samples in both composition and in physical properties, and how uniformly well they have withstood the conditions of actual service and the subsequent 20 sodium sulfate cycles. These figures amply support the statement that the slight variations found in the chemical and physical properties of commercially prepared slag are of no significance to the durability of the material and its quality for sewage disposal beds.

The sole function of the medium in a trickle filter bed is to provide a large amount of well aerated surface. To maintain proper circulation of air within the bed, the medium should have a high percentage of large voids. Hence, if a material has a large specific surface, its excellence for this use will depend upon the factors controlling its voids. These are sizing, cleanliness and durability. In this day when the washing of commercial aggregates is so common, it should not be difficult to secure material of the desired cleanliness. Likewise proper sizing should be entirely within the control of the engineer in charge of the job and the producer of aggregates. Judging from beds now in operation, sufficient attention has not been paid to this matter of sizing. The quantity of fine material below that specified, not infrequently runs to 15 to 20 per cent of the total. This very definitely reduces the voidage of the bed and hence the air capacity and promotes clogging. According to statements of state health officers of several states in the Great Lakes region, improper sizing has contributed more often to the poor behavior of beds in these states than has disintegration of the material after placement.

Size of Aggregate.—A tendency to raise the minimum size of material is evident. Taking the sizes specified for some 50 plants into consideration, the average size of aggregate for the upper part of the bed is found to have changed with time in the following manner: previous to 1910, 1.1 to 2.8 in.; 1910 to 1915, 1.2 to 2.5 in.; 1915 to 1920, 1.7 to 3.2 in.; since 1920, 1.8 to 3.3 in. It is logical to expect a continued increase in the smaller dimension since this will provide for larger voids and less opportunity for imperfect oxidation or for clogging.

Another evil attending poor sizing is the tendency for the fine material to concentrate in portions of the bed during placement unless special care is taken to prevent it. Such areas invite trouble such as pooling and clogging since they offer greater resistance to the downward movement of sewage and the solids carried thereby. If the material has the property of cementation, this will be most apt to occur in such areas of concentrated fine particles. It is doubtful if cementation ever results from the accumulation of fine material broken down from the grosser pieces by disintegration.

Occasionally a trickle bed is reported to be giving unsatisfactory service. Usually the filtering medium is blamed for this condition. However it is well to ask concerning the operating practices of the plant. There are several well-known cases of the unsatisfactory performance of sewage plants in which the trouble was not due to the aggregates. Beds of granite have clogged, pooled and flooded until cleaning was necessary, yet no characteristic of the stone contributed to this trouble. The only explanation lies in the improper operation of such beds. Overloading is the most frequent operation abuse. This factor probably accounts for more trouble than any other.

Poor screening and insufficient settling of the sewage permit excessive quantities of solid matter to pass upon the beds. The accumulation of this foreign material contributes definitely to the clogging of the filtering medium. Surface drainage carrying run-off sediment to the bed constitutes another source of trouble. Unless proper provision is made against it the filter areas may become littered with leaves and similar debris. Each of these operating factors may impair or destroy the efficiency of a trickle or contact bed otherwise in good condition.

Suggestions for Producers.—As practical measures for producers of filter bed media, the following suggestions are offered:

1. Establish the durability of the material by laboratory tests (preferably sodium sulfate) and if possible by observing its behavior on the surface of a bed in operation through one winter. Field observation indicates that the disintegration of aggregate takes place almost entirely at the surface of the bed and to the greatest extent during the first year or two.
2. The inspection and testing of the stone quarry, slag bank, or gravel pit is not of as great importance as the testing of the prepared aggregate of the size desired for that use.
3. Cleanliness and close adherence to the size specified are of the utmost importance. Such attention and effort will involve a slight additional cost, but it greatly improves the quality of the material and makes it distinctly worth more to the consumer.

Conclusions.—The conditions imposed by sewage disposal practice in which mineral aggregates are used in trickle filters or contact beds are very severe. However, aggregates of sufficient durability to be used in this practice are commercially available in most sections of the country. The function of the medium is to provide a large well aerated surface. To this end the proper sizing, cleanliness, placing, and the durability of the medium are of utmost importance. The first three of these factors can be controlled while the fourth can be predetermined with a sufficient degree of accuracy from soundness tests. Twenty sodium sulfate cycles with stone, slag and gravel aggregates indicate sufficient durability for satisfactory service as sewage disposal media. Many beds are now operating successfully in which the material will not withstand 20 cycles. The usually considered physical properties such as hardness, toughness, abrasion, etc., are of minor significance as criteria of the fitness of mineral aggregates in this field. Poor operation of a sewage disposal plant is frequently the cause of inefficient behavior of otherwise satisfactory trickle or contact beds.

Acknowledgment.—The above is a paper presented in the "Symposium on Mineral Aggregates" at the 32nd Annual Meeting of the American Society for Testing Materials, Atlantic City, N. J., June 24 to 28.

Sewage Treatment by Stream-Flow Aeration

An Improvement in the Activated Sludge Method

By HARRY N. JENKS and MAX LEVINE

Sanitary Engineer; Bacteriologist, Engineering Experiment Station, Iowa State College, Ames, Ia.

FOLLOWING various preliminary conferences, an agreement was effected during March, 1927, between Jacob E. Decker & Sons, of Mason City, Ia., and the engineering experiment station, Iowa State College, Ames, Ia., whereby a cooperative industrial fellowship was established for conducting packing-house waste disposal investigations and research. The writer assumed active charge of the project, to collaborate in the solution of the biological and sanitary engineering problems that presented themselves. Frederick G. Nelson, sanitary engineering graduate of the University of California, was appointed research fellow, in charge of field work at Mason City. Dean Anson Marston, as director of the engineering experiment station, has general supervision of all projects undertaken by the station.

Some time previous to the initiation of this project, the Executive Council of Iowa had taken mandatory action to secure the abatement of gross nuisance resulting from the discharge of industrial waste into Lime Creek, this action being based on the recommendations of the Iowa State Department of Health subsequent to a stream pollution survey completed by the division of sanitary engineering. The degree of treatment to be given the wastes was prescribed and a date fixed by which the Decker company, as one of the chief industries affected by the order, should comply with the new regulations. In order to determine by what means, if any, the proposed standard might be reached, either by a modification of the design and operation of the present activated sludge plant, or by some other process or combination of processes, the Decker company availed itself of the services which the engineering experiment station is in a position to render in such cases, through cooperative research in industrial wastes treatment.

During the course of their investigations relating to the Decker problem, the writers originated and studied experimentally a new means of sewage aeration, in an endeavor to ascertain the suitability of the activated sludge process under the best possible operating conditions. Because the new method simulates more closely than any other the basic phenomena responsible for the natural self-purification of sewage-polluted streams, it has seemed appropriate to designate it as a "stream-sewage treatment process." Systematic studies, both in the laboratory and in the field. have demonstrated the fact that, in practical operation, the stream-flow principle gives promise of furnishing an improved means of treating sewage and other organic wastes, as viewed from the standpoints of efficiency and of decreased cost of construction and operation.

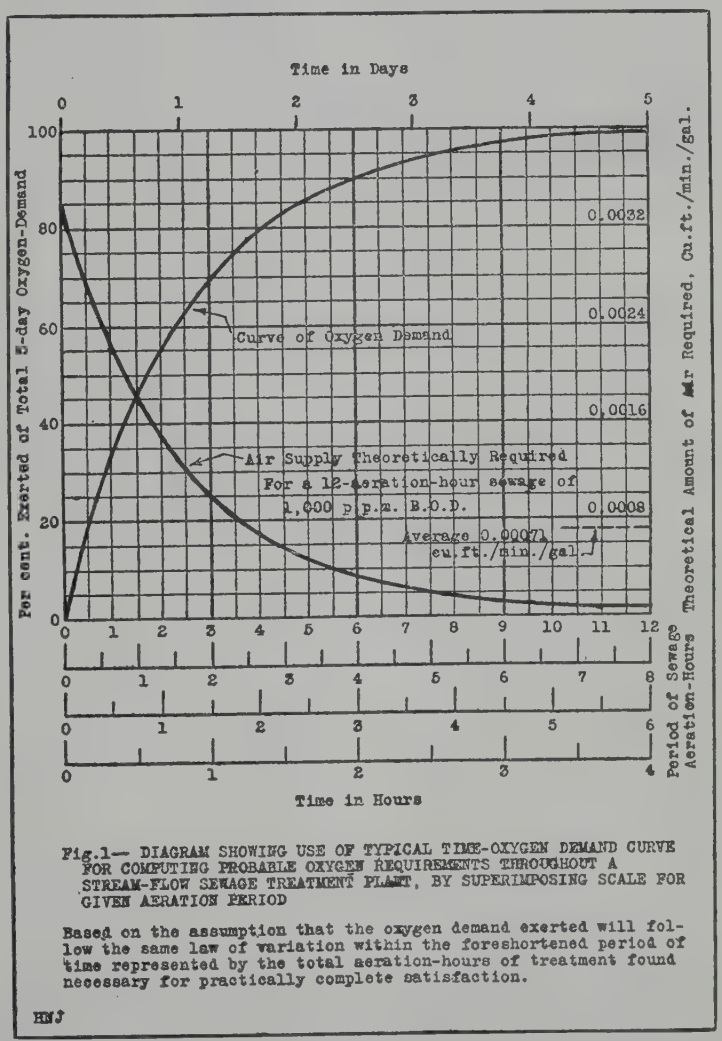

Fig.1— DIAGRAM SHOWING USE OF TYPICAL TIME-OXYGEN DEMAND CURVE FOR COMPUTING PROBABLE OXYGEN REQUIREMENTS THROUGHOUT A STREAM-FLOW SEWAGE TREATMENT PLANT, BY SUPERIMPOSING SCALE FOR GIVEN AERATION PERIOD

Based on the assumption that the oxygen demand exerted will follow the same law of variation within the foreshortened period of time represented by the total aeration-hours of treatment found necessary for practically complete satisfaction.

Fig. 1

Contrasts and Similarities in Aerobic Sewage Treatment.—When sewage is treated aerobically, the chief purpose of whatever process may be adopted is to bring the sewage and oxygen into intimate contact with each other. The present high regard in which the trickling filter is held is due in large measure to the effectiveness of this treatment device in maintaining aeorbic bichemical reactions resulting in a high degree of purification at relatively low operating cost. In the trickling filter the active biologic agents concerned in purification are in the form of a thin film which attaches itself to the filter material. As long as any given portion of this film remains in the filter bed it is stationary. This fact is responsible for a very important characteristic of trickling filters which manifests itself in the definite zoning of the biologic

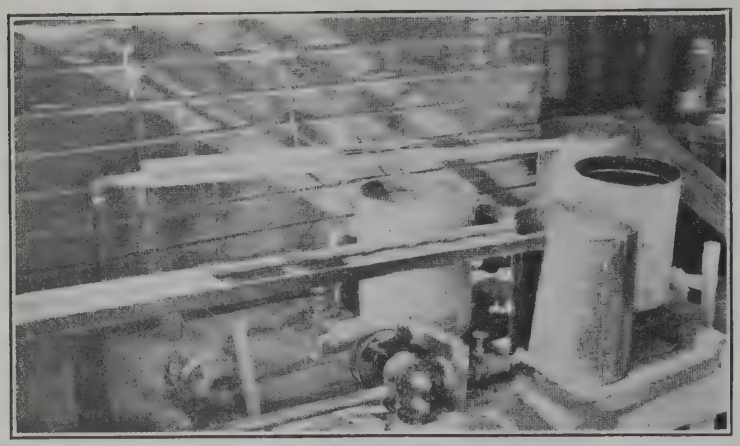

Fig. 2.—Laboratory Stream-Flow Sewage Treatment Plant, Showing Method of Recirculation of Sewage Over Reaeration Surfaces Discharging Into Oxidation Tanks. The Apparatus Is Here Arranged for Biologic Stage Treatment

life within the filter. As the sewage passes downward through the bed, the decomposition products of each stage of purification are successively removed to lower portions of the filter, where these products encounter organisms particularly adapted to the fermentation of such substances. Each zone, therefore, is largely washed free of the end products produced therein, so that these do not interfere with the biologic activity.

In sharp contrast with the trickling filter, the activated sludge process has several inherent disadvantages arising primarily from the fact that the purifying agents must be circulated through the sewage and, as ordinarily carried out, the process does not permit of an orderly biologic zoning, because of the promiscuous mixing of all the living forms that may be present in the activated sludge at any time. These organisms, upon which dependence is placed for the purification of the sewage, are continuously subjected to the inhibitory influences of their own end products until these products are decomposed by other microoganisms, and in each stage of the process the inactive organisms suffer considerable injury. Moreover, it is a difficult matter, when circulating the activated sludge through the sewage, to secure as intimate a contact with the organic matter to be absorbed as is evidently so well effected by the stationary sludge (jelly) adhering to the rock of a trickling filter. Here, also, the active agents are in the form of a thin film, while in the activated sludge process, when the oxygen is brought into the sewage by means of diffused air bubbles, much of the efficiency of surface-film contact is lost.

Finally, when sewage enters a stream and is subjected to the treatment process as evidenced in the self-purification of streams, there succeeds an orderly sequence of stages of oxidation accomplished by the different groups of organisms adapted to the environment present throughout each of these stages. Furthermore, the rate of absorption of oxygen, as defined by the rate of reaeration of the stream, is proportional to the dissolved oxygen deficit, which, in turn, is a reflection of the oxygen demand exerted by the sewage from point to point along the course of flow. In contrast with this situation under natural conditions, the air supplied in the activated sludge process is ordinarily the same in amount from start to finish. The resultant tendency is toward an insufficient supply at the beginning and an excess near the end, or else a waste of air throughout the aeration period.

Conception of Stream-Flow Aeration.—A critical review, such as has been outlined, of the advantages and shortcomings of the principal available methods of aerobic sewage treatment, leads to the conclusion that, in the final analysis, all so-called artificial treatment processes are simply adaptations of those found in nature. Further thought on this subject reveals the close analogy existing between the theory underlying the activated sludge process and the actual biochemical phenomena operative in stream flow.

Although the means which are employed to introduce the required oxygen into the zone of biochemical activity in the activated sludge process are strikingly dissimilar to the absorption of atmospheric oxygen in natural stream flow, yet this contrast is occasioned chiefly by difference in method rather than in principle. Moreover, the relatively short period of aeration, measured in hours, provided in the artificial process, is simply an acceleration of the process of decomposition, extending over a relatively prolonged period, measured in days, throughout which the oxygen demand is being exerted and finally satisfied, in a flowing stream. Taking the natural process as a basis of comparison, it is observed that the advantage lies with the artificial process in respect to the time factor of purification, a result attained by virtue of the presence of the artificially developed activated sludge. On the other hand, it is apparent that in the natural self-purification of streams the direct absorption of atmospheric oxygen without the employment of extraneous mechanical power other than an equivalent small loss of head, coupled with the absorption of such oxygen in proportion to the oxygen deficit only, is a manifestation of the economy of nature which the existing artificial process very imperfectly applies. The truly enormous weight of oxygen appropriated from the atmosphere by streams, through surface reaeration, comes as a surprise to engineers who are aware only in a general way of this phenomenon, and it can not fail to impress any one making the detailed computations required for studies of the oxygen balance in streams.

For some time past, the writers, in common with other workers in this field, have been impressed with the quite evident wastefulness of the present methods of introducing compressed air, through diffuser plates, into the body of sewage passing through the aeration tanks of an activated sludge plant. By waste of air is meant, in the present discussion, the use of air for other than its appropriation by the aerobic organisms for the oxidation of the organic matter. That the amount of air, and consequently the expenditure of power, is greatly in excess of the theoretical requirements for the satisfaction of the oxygen demand is clearly indicated by Fig. 1. On this diagram a curve is drawn showing the air supply theoretically required for an industrial sewage having an initial five-day oxygen demand of 1,000 p.p.m., and is based on the assumption that the rate of satisfaction of this demand will proceed substantially in conformity with the general course of the deoxygenation curve proposed by Phelps and later more fully confirmed by Theriault during the latter's studies on the pollution of the Ohio River.[1] Although deoxygenation in the presence of activated sludge, and the consequent need for oxygen to supply the resulting deficit, may doubtless be found, upon further study, to proceed at numerically different rates than those in the ordinary cases considered; yet the authors have determined that the typical five-day deoxygenation curve quite well defines the general relative magnitude of the oxygen demand during successive periods of time, measured, in the present instance, in hours of aeration. From Fig. 1 it may be observed that the average theoretical requirement for air to remove 99 per cent of the oxygen-demanding con-

[1]Phelps, E. B. (1909): The Disinfection of Sewage and Sewage Filter Effluents. U. S. Geological Survey Water Supply Paper 229, pp. 74-88.

Also Theriault, E. J. (1927): The Oxygen Demand of Polluted Waters. Pub. Health Bull. No. 173, p. 131 et seq.

stituents from a 12-aeration-hour[2] industrial waste of 1,000 p.p.m. initial biochemical oxygen demand is only slightly more than ½ cu. ft. per gallon, whereas the normal use of air in practice might be from 4 to 6 cu. ft. per gallon for such a waste.

Aside from the wide divergence between the theoretical and actual requirements for air for oxidation purposes, the current practice of supplying the same amount of air per unit volume of sewage, from beginning to end of the aeration period, is not in conformity with the fact expressed by Phelps that "the rate of biochemical oxidation of organic matter is proportional to the remaining concentration of unoxidized substance, measured in terms of oxidizability." To take this condition into account requires the introduction of oxygen at the maximum rate at the beginning of the process, followed by a gradual reduction of air supplied, corresponding to the decreasing oxygen demand exerted, until the completion of the aeration period is reached.

Engineering Design of Basis of Stream-Flow Reaeration.—The theory of reaeration and its application to problems of stream pollution encountered in practice have had extensive treatment in current technical literature, notably by Streeter and Phelps,[3] in a classic contribution to our knowledge of the physical factors involved in the self-purification of natural streams. The definite, quantitative relationships discovered by these investigators and formulated mathematically for use in computing reaeration rates furnished valuable collateral evidence as to the correctness of the basic conception for the engineering design of a sewage-treatment plant on the stream-flow principle, presently to be described. In such a plant the oxygen requirements are met through surface reaeration of the sewage under optimum conditions as found in natural water courses.

Streeter's investigation showed that the rate of reaeration, designated by him by the symbol, K_2, is defined mainly by the temperature, oxygen saturation deficit, and the turbulence of the stream. In a sewage-treatment plant employing the stream-flow principle it was conceived that the factor of turbulence should be brought into play to the best possible advantage. Turbulence itself being an abstract characteristic, Streeter defined it in terms of velocity and depth, and determined empirically the validity of the following relationship:

$$K_2 = \frac{cV^n}{H^2}$$

where K_2 = coefficient defining the rate of reaeration;
V = velocity of the stream in feet per second;
H = mean depth of flow in feet;
c = constant depending chiefly upon irregularities in different stream stretches, producing turbulence; and
n = constant defining the variation in reaeration rates in the same river stretch for different flow conditions.

In analyzing the numerical values of (n), Streeter found that, when the channel conditions are such that a 5-ft. increase in stage produces from 2 to 7 ft. per second increase in mean velocity, little change in the value of (n) occurs, its actual value at the upper end of the velocity range being slightly greater than unity. In such a case the influence of the velocity itself predominates over that of turbulence.

Regarding the values of (c), it was concluded that the slope and irregularity of the channel are probably the governing factors. Available data on the Ohio River tend to show that the irregularity factor itself loses most of its effect when the slope approximates 2 ft. per mile. With greater slopes than this, corresponding values of (c) increase at a much more rapid rate.

In concluding his analysis of the factors influencing the value of K_2, Streeter shows that there is a "tendency for K_2 to reach a maximum with increasing velocities of flow up to a certain point. * * * The velocity of flow coinciding with this maximum K_2 point varies in different river stretches studied, but in a majority of them it is reached at somewhere between 2 and 4 ft. per second."

Holding in review the conclusions set forth by Streeter and his collaborators in relation to stream-flow aeration, it is apparent that this natural phenomenon can be directly applied to the treatment of organic wastes by providing an engineering design in which the maximum value of K_2 should be obtained. This object may be reached by means of a controlled section of stream channel in which the proper depth and velocity can be maintained. In natural streams the decomposition of the sewage proceeds over a long course of flow, many miles in length, so that it was recognized that within the physical limits of a treatment plant the necessary time element, in terms of distance traversed, could not be introduced in this way. Accordingly, recirculation of the sewage over the controlled section was decided upon and the design of the plant was made in accordance with the following basic assumptions:

(1) The rate of biochemical oxygen satisfaction will proceed, in the presence of activated sludge, substantially in accord with the deoxygenation curve as derived for flowing streams, except that the biochemical oxygen demand will be fully exerted and satisfied within a foreshortened period of time. (See Fig. 1.)
(2) The effect of reaeration may be closely simulated by exposing the sewage flow in thin sheets to the atmosphere by recirculation over a reaeration surface comprising a controlled stream section distinctly separate from the zone of biologic activity wherein the oxygen so absorbed is utilized.
(3) The rates of recirculation of sewage over the reaeration surfaces at different points throughout the aeration period shall be adjusted to the actual biochemical oxygen demand correspondingly exerted.

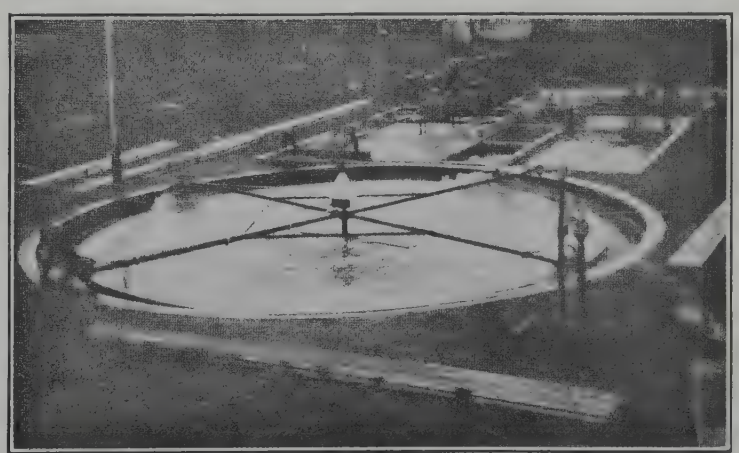

Fig. 3.—Practical Scale Field Installation of Stream-Flow Plant for Treatment of Packing House Wastes. General View of Reaeration Units and the Types of Pumping Equipment Devised for Test Purposes

[2]The term "aeration hours" refers here to the ascertained period of aeration needed to effect the maximum reduction of biochemical oxygen demand of which the process is economically capable when treating the sewage in question. Thus, a sewage requiring six hours' aeration for satisfactory treatment on this basis, may be referred to as a six-aeration-hour sewage.

[3]A Study of the Pollution and Natural Purification of the Ohio River. Public Health Bulletin No. 146, U. S. Public Health Service (1925).

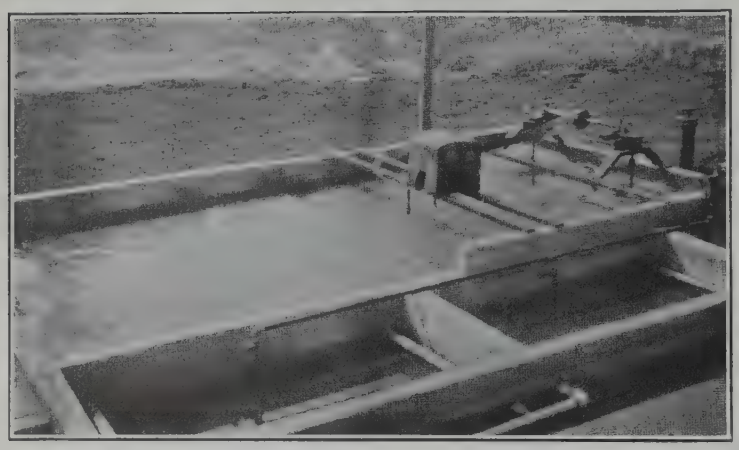

Fig. 4.—View of Primary Stage Aeration Unit of Practical Scale Stream-Flow Sewage Treatment Plant, Showing the Realistic Manner in Which the Recirculation of the Sewage Over the Reaeration Surfaces (to the Right) Simulate the Rills and Riffles of a Rapidly Flowing Shallow Stream. Illustration Shows Propeller Blade Pumps in Operation in This Unit

The physical construction which a stream-flow plant thus assumes was seen to involve essentially a biochemical oxidation zone contained in a tank or basin through which the main body of sewage progresses and a separate reaeration or oxygen-absorbing zone, embodied in a paved surface adjacent to or over the tank, over which an independent and concomitant recirculation of the organic wastes is maintained. The sewage is withdrawn from the oxidation zone, discharged onto the reaeration surface, and allowed to flow down the slope of this surface, thence returning into the oxidation zone within the aeration tank.

In comparing the stream-flow plant design conditions with the relationship $K_2=cV^n/H^2$, it will be noted that the minimizing effect of (H) may be practically eliminated by making the depth from 0.5 to 1 in., thus presenting the maximum surface practicable for a given volume of sewage recirculated over the reaeration surface. The desirable velocity of flow over this surface to prevent deposition of sludge was assumed to lie between 2 and 3 ft. per second, which corresponds closely with the range found by Streeter to be conducive of maximum values of the reaeration coefficient K_2. It has been determined that a slope of ½ in. per foot will give closely the desired velocity, even when transverse cleats are placed in the reaeration channel to induce riffling. As this slope is greatly in excess of the 2 ft. per mile, above which point the value of (c) increases most rapidly, the effect of such a slope is very favorable to increased values of K_2. Finally, as regards (n), in a channel of the type under consideration the hydraulic radius increases rapidly with increased depth, so that the velocity effect itself predominates, with a value of (n) close to unity; this is also true on account of the negligible effect of the depth (H). The conditions of flow, therefore, in a stream-flow plant are the counterpart of a natural stream progressing through a long series of riffles and pools, a condition known to be most favorable to self-purification within a minimum distance, measured in time.

Installation of Practical-Scale Stream-Flow Plant.—After the stream-flow idea had been given a thorough preliminary trial with the laboratory apparatus shown in Fig. 2, operating on milk wastes up to 2 per cent concentration and yielding results presented at a later point in this article, a practical-scale field plant was constructed at the Decker packing plant. Fig. 3 is a photograph of this installation, showing the general arrangement of the plant and types of pumping equipment employed for test purposes. Fig. 4 is a view of the second aeration unit (tank B indicated in the flow sheet of Fig. 5), taken to illustrate the realistic manner in which the recirculation of the sewage simulates the rills and riffles of a rapidly flowing shallow stream.

The structural features of a stream-flow plant, except for the aeration units, conform in essential particulars to the general design followed in the case of the activated sludge process. That is, a complete installation might comprise preliminary settling tanks, or screens, and final sludge settling tanks, together with appurtenances, in addition to the stream-flow aeration units themselves. As there is nothing in the aeration units to become clogged, whatever removal of suspended matter may be effected will be done to lessen the biochemical oxygen demand of the influent, or to recover such organic solids as may be utilized in the by-products department of the industrial plant producing the wastes. The provision of pretreatment by sedimentation thus becomes a matter of economics rather than one of necessity.

Effect of Recirculation on Retention Period.—In practice, circumstances will dictate as to the position of the inlets and outlets of the various tanks or basins and of the recirculation piping. Because of the removal and return of the sewage flow as it passes through each of the oxidation tanks or the various compartments of a single tank, it is evident that there will be an indeterminate amount of short-circuiting of the tank contents from inlet to outlet. The crude or average retention period is computed on the actual displacement basis, although in fact the aeration period of successive volumes of flow is variable.

The situation with reference to effects of short-circuiting may be regarded as analogous to that which prevails in regard to the flowing-through period in mechanically operated mixing tanks. This matter was thoroughly investigated in connection with the design of the coagulation tanks for the Sacramento, Calif., filtration plant under the direction of Charles G. Hyde, chief consulting engineer, and based on the original research work of W. F. Langelier. Professor Langelier concluded from experiments[4] that the probable under-treatment due to short-circuiting may be expressed by the formula

$$X = 1 - [1 - (1 - R/Q)^{t/n}]n$$

Where Q = capacity of each tank in gallons;
R = flow of water (gallons per minute);
n = number of tanks;
t = minutes actual retention in n tanks;
X = proportion of water remaining in tanks t minutes (or longer).

The formula is based on the assumption of practically instantaneous diffusion of incoming water with tank contents.

Curves based on the foregoing expression show that when there are two or more tanks, short-circuiting is greatly reduced, the number of tanks having a much greater effect than their capacity in obviating undertreatment due to short-circuiting. From actual operating experience at the plant mentioned, Jenks found that the proportion of total flow escaping adequate coagulation, or its retention equivalent, is negligible when three or more tanks are operated in series. It is concluded that similar results are to be expected from the aeration units of a stream-flow plant.

Pumping Equipment for Reaeration.—The manner of maintaining the auxiliary recirculation of the organic wastes through the reaeration system, as the main body of sewage progresses through the oxidation tank, is a matter to be decided upon the basis of convenience and cost. It will be recognized that the pumping problem here is

[4] Coagulation of Water with Alum by Prolonged Agitation. Eng. News-Record, vol. 86, No. 22, pp. 924-928 (1921).

a most unusual one, involving as it does the discharge of relatively large volumes of sewage against an extraordinarily low static head, amounting to perhaps not more than 4 to 6 inches. Of the standard forms of pumps, the screw pump offers one of the best means of meeting these operating conditions at a reasonable efficiency. Such a pump might, however, be unduly expensive when designed specially for an extremely low head. Accordingly, three special pumping mechanisms, such as might be fabricated in a local machine shop, were devised for the Decker experimental field plant. Tank A was provided with a plow pump; tank B with a propeller pump; and tank C with a plunger box pump. The general view of the plant, shown in Fig. 3, indicates these devices in operation. Their suitability for this service is being studied comparatively to determine which design might be used most advantageously.

Plant-Operating Data.—The operating results obtained from the stream-flow plant are based on an extensive series of tests, with the laboratory-sized plant (Fig. 2), on milk wastes, packing-house wastes, and sugar-beet wastes. The satisfactory treatment of these wastes from the standpoint of biochemical oxygen demand reduction, development and maintenance of an excellent activated sludge, and elimination of acid-producing constituents, led to the design and construction of a practical-scale field plant at the Decker packing plant. This installation enables a study to be made of the mechanical, hydraulic, and general engineering features of the new design.

Aeration Efficiency.—The efficiency of the stream-flow principle of aeration has been shown to be consistently as good as that of diffused air when treating the industrial wastes already mentioned. Illustrative of the results obtained on packing-house wastes (Decker), Table 1 is presented, which shows the reduction in biochemical oxygen demand after various aeration periods. The data are based on six weeks' operation, and the results are listed in the order of their occurrence. It will be noted that although the wastes being treated may be considered a 12-aeration-hour sewage, yet a remarkable reduction in b.o.d. occurs after only 6 hours' aeration.

As to comparative efficiency of stream-flow aeration, it is believed that the continual exposure of the sewage to the atmosphere, as it flows over the reaeration surfaces in thin films, more closely approaches the optimum conditions for oxygen absorption than any design heretofore proposed.

Effect of Biologic Staging.—The division of the treatment process into two or more stages, developing and maintaining a distinctly separate activated sludge for each stage, was conceived as a means of favoring increased biologic efficiency on the basis of the considerations relating to biologic zoning of trickling filters, as discussed at the beginning of this article. That this reasoning is essentially correct is evidenced in part by the results of stage treatment given in Table II showing that nitrification was secured by this means when treating 2 per cent milk waste by stream-flow aeration units. It may be noted that whether a primary stage of 6 hours was succeeded by a secondary stage of 18 hours, or the process reversed, nitrification for this type of waste ensued. In contrast with these results, Levine showed in previous research on the treatment of milk wastes that even with an unlimited supply of diffused air it was impossible to produce nitrates in single-stage treatment by the activated sludge process.[5]

Although the writers are aware that some engineers may be of the opinion that stage treatment does not commend itself on economic grounds for domestic sewage, yet they are convinced that biologic stage treatment merits serious consideration as an important aid in enhancing the efficiency of the activated sludge process where the more concentrated industrial wastes are concerned. This conception of the logical and proper method of operating an activated sludge plant is being given further study in the field stream-flow plant at Mason City. It appears that at least one important point that has heretofore not been adequately emphasized is the great advantage of removing as quickly as possible, from the aeration tanks, all excess sludge with its own high oxygen demanding characteristics gained by absorption from the wastes being treated. This can be accomplished by intermediate settling between stages, and so lessen the oxygen demand of succeeding stages. To take advantage of this fact, the Decker practical-scale stream-flow plant provides stage treatment in accordance with the flow sheet shown in Fig. 5.

Power Requirements for Stream-Flow Aeration.—It can be shown by computations based on the deoxygenation curve described in a previous section of this article, and corroborated substantially by experiments, that a packing-house waste such as that found at the Decker plant and referred to in Table I can be treated by the stream-flow method through 12 hours' aeration, involving the recirculation of approximately 125 times the volume of sewage flow. Similar methods of computation applied to the case of a domestic sewage containing some industrial wastes, resulting in a biochemical oxygen demand of 350 p.p.m., should be successfully treated through six-hour stream-flow aeration of 50 times the volume of flow. For the latter case, assuming conservatively a lift of 4 in. and an over-all pumping efficiency of 25 per cent water level to water level, the required energy for aeration should not exceed 12 hp. per m.g.d. treated.

It is realized that only actual operating experience with a full-sized installation can demonstrate the correctness of such a power estimate. Yet, the order of magnitude of the power required is such that a considerable factor of safety might be introduced without seriously detracting from the favorable comparison that can be drawn between the stream-flow plant and existing means of sewage aeration. In fact, if sufficient difference in elevation exists at the treatment-plant site, it is possible to design the plant in such a manner as to obviate a substantial part of the recirculation pumping through

the utilization of this available head. In such an event the conditions of aeration would closely approximate those found throughout the course of a natural stream bed.

Cost of Construction.—In the construction of a stream-flow plant it will be observed that it may be built so as to require relatively little excavation. In general, if excavation costs are high in comparison with the cost of area of land covered by the plant, then the tanks may be made quite shallow. For small plants it is suggested that the depth may be 4 to 6 ft. No dependence upon depth is required to provide a proper contact period of the air with the organic matter, which is a practical necessity in the diffused-air activated sludge aeration tank. The operation of the tanks entails the usual low loss of head resulting from flow through unbaffled basins at low velocities.

The stream-flow absorption of atmospheric oxygen insures an adequate oxygen supply without any expense for installation and operation of air piping and diffuser plates. Also, in comparison with air-washing and air-compressing equipment and machinery used in diffused-air plants, the extremely low-head pumping equipment and simple piping alone needed in the stream-flow plant is far less expensive, both in first cost and in operation.

It is suggested that for a plant to treat, say, 2 m.g.d., the first tanks might be provided with screw pumps discharging from 6,000 to 8,000 g.p.m. each. In the last tanks, where the recirculation rate is greatly reduced, plunger-box pumping units might be employed, operated by a common roller-bearing crank shaft, along each side of the tanks. In connection with studies of pumping requirements, an apparatus of unique design is being tested, by which advantage may be taken of the very low lift to utilize effectively the velocity head created by the pump impeller, operating on the vortex principle.

The reaeration surfaces may partly or wholly cover the aeration tanks or be laid as a pavement on natural ground along the edge of the structures. If the oxidation tanks are made of conventional depth, then the stream-flow aeration units will occupy very closely the same area as aeration tanks designed in the ordinary way. This is an important point which has been rightly emphasized by Streeter in discussing the relative economy of area required by various aeration devices typical of British sanitary engineering practice.[6] Experiments indicate that the reaeration surfaces should be from 6 to 10 ft. in length, providing three to five seconds' exposure of the sewage film to the atmosphere at 2 ft. per second velocity. A design factor will be determined empirically which will give the permissible recirculation rate in g.p.m. per square foot of reaeration surface. If required by severe weather conditions, the reaeration surfaces may be readily covered, air being admitted through suitably spaced ventilators.

It is not possible within the scope of this article to review the results obtained by other investigators in the field of sewage aeration by mechanical agitation, in order to point out the essential similarities and differences between stream-flow aeration and that secured by other means. It is the authors' hope that, after they and others who will become interested in this subject have fully overcome the difficulties that will naturally be encountered in the practical application of so novel a form of sewage-treatment plant, it will become a fitting engineering counterpart of the notable advances made by British engineers in the use of mechanical aeration in the activated sludge process.

It gives the authors pleasure to acknowledge at this time the very gratifying cooperation of the Jacob E. Decker & Sons organization, particularly on the part of Jay E. Decker, president, E. S. Selby, treasurer, and Elmer E. Dye, chemist of that company. Acknowledgment is also due all members of the engineering experiment station staff who have been interested in the furtherance of this project, among whom Harry E. Goresline, assistant bacteriologist, and George W. Burke, chemical engineer, have rendered valuable assistance in the laboratory work. Credit is also due Robley Winfrey, assistant director, for his helpfulness at all times in arranging the necessary financial and organization details of the project.

Acknowledgment.—The above article is taken from the Sept. 28 Public Health Report.

Selecting Material for Earth Dam

Methods Employed for Granville Dam, Westfield, Mass.

By CHARLES TERZAGHI
Professor of Foundation Engineering, Massachusetts Institute of Technology, Cambridge, Mass.

THE information obtained by exploring the proposed borrow-pit area on the left side of the dam was sufficient to show that by far the most suitable dam-construction material is located above elevation 560 (more or less) on top of the deposit of reddish sand.

By excavating additional test pits we learned that the composition of the deposit in the borrow-pit area is almost as variable as the composition of all the other deposits found in the vicinity of the dam site. Thus the question arose as to how we should determine during construction whether any newly-opened section of the borrow pit would furnish material with a sufficiently low average coefficient of permeability to permit its use. Since by necessity tests are restricted to samples selected at random, while the coefficient of permeability is apt to change from foot to foot, it seemed preferable to obtain approximate results for a great number of samples rather than accurate results for a few.

Method of Estimating Coefficient of Permeability.—To reduce the time and labor required for estimating the coefficient of permeabiliay of samples, we developed a method based on the fact that the speed of capillary rise of water through soil becomes less as the soil is less permeable. The theory of the process is somewhat complicated, because the speed of upward movement depends not merely on permeability but also on the ultimate height of the water level. Due to this complication there merely exists an approximate proportionality between the speed of capillary rise and the reciprocal value of the coefficient of permeability. A further complication is introduced by the fact that some air is retained within the voids of the soil while the water moves upward. Nevertheless, the fact remains that the steepness of the curve, which represents graphically the speed of capillary rise, increases with the permeability of the material. Figure 1 shows curves for those samples whose permeability was accurately determined. By observing the capillary upward movement for any sample and by plotting the results on Fig. 1, one can roughly estimate the coefficient of permeability of the material.

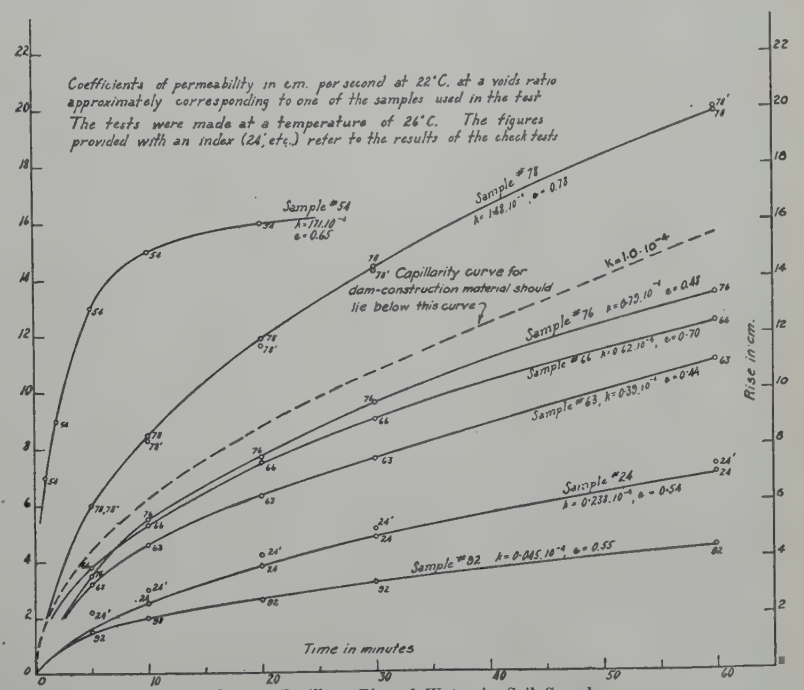
Testing Device and Procedure.—The device for making the tests is shown in Fig. 2. It consists of a simple tank (A) made of sheet tin, an irrigator for feeding the tank, and a set of glass tubes (G), made of hard glass. Hard glass is essential, otherwise the cylinders invariably break during the tests. The bottom of each glass tube is covered with a brass wire screen stretched across and soldered to a brass ring. In order to test a sample, the procedure is as follows:

The sample is dried on a stove, after which it is placed in one of the glass tubes, in layers 2 cm. thick, until the cylinder is completely filled. Each layer is compacted by lifting and dropping ten times from an elevation of 4 in. a cylindrical pestle made of hard wood, with a diameter of 1¼ in. and a weight of 150 grams. In case the sand grains are smaller than the openings of the sieve, a 2 or 3-mm. layer of coarse sand is placed on the sieve before the first layer of the sample is introduced. In the meantime the tank is filled with water supplied from the irrigator, the excess water passing over the crest of the overflow (W) and draining away through the discharge pipe. As soon as the cylinder is filled with the sample, the brass sieve is wetted with a mist cloth and the cylinder is placed on the immersed support (S), as shown in Fig. 2. Care should be taken to keep the cylinder in a slightly inclined position while lowering it through the surface of the water so as to offer a chance for lateral escape of air.

As soon as the base of the glass cylinder touches the surface of the water, the water starts to rise by capillary action within the sample, as indicated by the color of the sample turning dark. The smaller the permeability of the sample, the slower is the upward movement of moisture. Readings of the rise in water level are taken 5, 10, 20 and 30 minutes after the test is started. The simplicity of the necessary operations permits six tests to be carried on simultaneously.

Observation During Construction.—After the report on the soil studies was presented, the underground strata were exposed to direct inspection by the construction of the core trench and the excavation of the borrow pits. It was found that the underground conditions checked with the predictions. The right (southern) wing of the dam rests against a very feeble permeable portion of the south slope. The permeability of the material from the borrow pit averages, according to the results of the capillary tests, 0.000068 cm. per sec., which is below the value of 0.0001 cm. per sec., on which seepage computations were based. The layer of boulders, which covers the bottom of the valley is strictly confined to the area between the slopes. Although the material was found to be very compact, the core wall was constructed so as to prevent subterranean erosion along individual seams or channels. The bed rock was more badly shattered than was expected from the drilling records; as a consequence it had to be grouted.

In order to exclude borrow-pit material that is more permeable than we intended to tolerate, a curve (k) was traced on Fig. 1, corresponding to the capillarity curve of a material with a coefficient of permeability of 0.0001 cm. per sec., on which the estimate of seepage losses was based. From time to time, particularly in case a stratum of doubtful quality was encountered, samples were tested by means of the



Coefficients of permeability in c.m. per second at 22°C. at a voids ratio approximately corresponding to one of the samples used in the test. The tests were made at a temperature of 26°C. The figures provided with an index (24', etc.) refer to the results of the check tests

apparatus shown in Fig. 2, with the intention of excluding from use in the dam any material whose capillarity curve is located above curve (k). The material in which the steam shovel worked, was more or less stratified, but when it broke off the bank and was picked up by the shovel, it became well mixed so that the samples taken from the trucks were fairly representative.

Testing Embankment Material.—During construction, two questions arose concerning methods for testing embankment material: First of all, whether or not the drying of the material in the stove has any influence on the results of capillarity tests and second, whether the volume of voids of the material in the embankment is smaller or greater than the volume of voids obtained when compacting the material in the standpipe of the capillarity apparatus. Due to the great influence of the volume of voids on permeability, the second question was of vital importance.

Concerning the first question, we found that the drying process had no appreciable effect on permeability, inasmuch as the tests with air-dried and with stove-dried sample gave practically identical results. In order to answer the second question, undisturbed samples were secured from a pit excavated in the finished embankment. Excavation of the pit was difficult and required the use of pick and shovel, which demonstrates the excellent results obtained by compacting with Caterpillar tractors. Due to the presence of many stones in the fill, a cylindrical sampler with cutting edge could not be used. Hence, large chunks of soil (up to ¼ cu. ft.) were removed and sealed on the ground by repeatedly painting their

Permeability Loose
Permeability Computed
0.365 = Void Ratio in the Dam
Coefficient of Permeability in Cm. per second
Voids Ratio

Fig. 3—Relation Between Void-Ratio and Permability of Loose and Compacted Soil

surfaces with hot paraffin. In the laboratory the volume of the sealed chunks was determined by immersing them in water. Afterwards the chunks were skinned and the original and dry weight of the chunks and the specific gravity of the solid constituents were determined. From these data was computed the volume of voids of the more fine-grained mass that filled the interstices between the stones. This volume of voids was found to be equal to 26 per cent of the total volume. Finally, the more fine-grained material was transferred into a permeameter, and the permeability was determined in a loose and in a compacted state. At this time we learned that it was practically impossible to bring the density of the material in the permeameter, by ramming it in a moist condition, up to the density of the material in the embankment. Figure 3 shows the test results. These indicate that permeability decreases with decreasing voids-ratio much more rapidly than one would expect. This was due to the appreciable mica-content of the sample. From previous experience we know that the finer the soil and the greater the percentage of scale-like particles, the steeper is the voids-ratio-permeability curve. Figure 3 also shows that the voids-ratio of the sample compacted in the standpipe of the capillarity apparatus is considerably greater than the voids-ratio of the material in the embankment (0.464 against 0.366). Hence, the factor of safety against excessive percolation is ample when computations are based on the results of capillarity tests.

The method of keeping track of the quality of the dam-construction material by means of capillarity tests was found to be satisfactory except in so far as the relation between permeability and the speed of capillary rise depends to a certain extent on the character of the sand grains and silt fraction. For this reason two materials with equal permeability are apt to have two somewhat different capillary-rise curves, and a set of curves similar to those in Fig. 1 cannot be depended upon except for the same class of materials. In order to eliminate this shortcoming, modifications of the testing procedure are under consideration.

Acknowledgment.—The above is an extract from a paper in the June issue of the Journal of the New England Water Works Association.

Serious Water Famine in England

Press dispatches from London, under date of July 17, state that England is suffering from a very serious water famine due to lack of rainfall. Official appeals for the most rigid economy have been made nearly everywhere in the largest cities and in the smallest villages. The situation is critical for households and industries.

So serious have matters become in the woolen mill district of Yorkshire that general restrictions have been introduced. On the above date Dewsbury had only a twelve hours' a day service and thirty-one days' supply, while the neighboring town of Batley had only fifteen.

Conditions are serious in the villages surrounding Oxford. In the Crown Marsh rural area water must be carried in barrels half a mile. At St. Eventon in Berkshire there is a supply only on alternate days, while at Milton the supply has been cut off between 1 in the afternoon and 8 in the morning.

Unless rain falls soon, Boston will be faced with a repetition of the 1921 water famine, when supplies had to be brought from Willoughby by rail. The brook at Miningsby, Boston's regular source of supply, dried up three years ago, leaving the town dependent on the waterworks company's single reservoir.

Throughout the country warning notices have been posted and handbills have been distributed requesting the public to be careful in the use of water and to refrain from watering gardens and washing automobiles.

Recent Developments in Water Works Field

Abstracts of Papers Presented at Toronto Convention of American W. W. Assn.

Manganese Dioxide Deposits in Catskill Aqueduct

The Cause and the Proposed Remedy

By FRANK E. HALE
Director of Laboratories, Bureau of Water Supply, New York City

THE Catskill aqueduct from Ashokan reservoir to Kensico reservoir was first put into service late in 1915 to serve a portion of the Bronx. Early in 1917 the full available quantity of water from Esopus Creek was brought down to supply portions of all boroughs of New York City. Chlorination at Ashokan headworks was placed in regular operation January 10, 1925. On December 11, 1924, the flow of water in the aqueduct was increased to maximum capacity, approximately, due to the fact that a portion of the Schoharie development became available. In the aqueduct there is visible evidence of the average flow of water at two levels representing about 400 m.g.d. and 600 m.g.d.

1 In. Deposit Formed.—It was noted that a brown deposit formed on the walls of the aqueduct up to the original water level and that this deposit exercised considerable influence upon the amount of water flowing through the aqueduct. The deposit reached as much as 1 in. in thickness near Ashokan reservoir, prior to chlorination.

The increased flow in the aqueduct and chlorination were introduced at about the same time. Following chlorination the deposit reduced in thickness, became detached in large areas, and less effect was noted on the available capacity of the aqueduct. The matter seemed of sufficient importance to ascertain the character of the deposit, its distribution, the extent and reason for the influence of the chlorination, with a view to ascertaining whether the introduction of additional chlorination at intervals and at points further down the aqueduct would be feasible and desirable for the purpose of increasing the available capacity of the aqueduct.

Consequently the aqueduct was emptied and inspected on Oct. 8, 1928, between Ashokan and Kensico reservoirs at numerous points and samples of the deposit taken for examaintion.

The coating consists of a soft, very dark brown substance (chocolate color), with the exposed surface of a polished or greasy appearance, much like dark wet mud. This can be readily scraped off, being only loosely attached, and patches had been removed by the flowing water and large portions had slipped down near the bottom. Where the entire area in contact with the water was found coated, the surface was uneven, similar to a "spatter-dash" finish obtained with thin mortar. The surface of new coating resembled a "stippled" finish.

The surface of the concrete beneath the coating had a rough sand finish, due to solution of cement at the surface.

Chlorination Reduced Thickness of Deposit.—The effect if the chlorine had been to reduce the thickness of the deposit, possibly hasten its detachment in areas, and prevent new deposit on fresh cement surface thus uncovered. It was also noticeable that between the old and new water levels no deposit had taken place. This effect of the chlorine reached many miles down the aqueduct since the first new deposit was noted at Newburgh, 37 miles from Ashokan reservoir, and the old coating patches were thicker (¼ in.) than at the point above (⅛ in.) 24 miles. At 48 miles and below, across the Hudson, the entire surface was again coated.

The seven samples were examined microscopically both with and without treatment with dilute hydrochloric acid and there was absolutely no indication of any microscopic plant growth nor organic structure.

All of the above samples were dried in oven at 105 deg. C. The loss on ignition was then determined on these dried samples, measuring water of hydration. During this ignition there was absolutely no odor or organic matter nor any evidence of black char. This would indicate that the deposit was entirely of mineral character.

Qualitative tests of the deposit for the presence of manganese dioxide showed it to be abundantly present. For example, treatment with hydrochloric acid (1:1) produced sufficient chlorine gas to be strongly visible and odorous and heating produced a strong evolution of green chlorine gas, leaving the residue pale pink.

Analysis of Samples.—As there was every indication that the deposits were more or less alike, only samples Nos. 1, 4, 5 and 7 were given detailed analysis, Nos. 1, 4 and 7 being representative of the nearest point to Ashokan, an intermediate point, and the furthest point sampled. No. 5 represented the new growth. In taking these samples it was noticeable that the cement surface had been dissolved by the water, leaving a rough surface of small sand grains. These were obvious also in the samples examined. Under the heading of "Sand and cement from the walls" has been included the insoluble in hydrochloric acid and the soluble silica, lime and magnesia. The last three were very small in amount, ranging from 1½ per cent to 3½ per cent of the total dried weight of deposit. The constituents of the brown deposit have been calculated on a basis of absence of sand and cement from the walls.

The chemical analyses of these samples are as follows (Table I.):

The amount of sand and cement varies inversely with the thickness of the brown deposit due to variation in amount of scraping of the walls in obtaining samples. The deposit from which No. 5 was taken was very thin hence contained much more sand.

Manganese Present in Supply.—It is obvious that the largest constituent of this deposit is manganese dioxide. Determination for manganese in the Catskill water as it leaves Ashokan reservoir showed it to be present at this time to the extent of .04 ppm. It is also present in the Croton supply to the extent of .08 ppm. which is sufficient to cause deposit of manganese dioxide in the bottom of Croton Lake, which is disturbed by the fall over-rising to such an extent that visible brown floc of manganese dioxide is present in the Croton aqueduct water in the fall of the year. This manganese dioxide explains the orthotolidin reaction appear-

* No char nor organic odor.

ing before chlorine is added and which regularly increases every fall dropping to almost nothing in winter. Judging from the phenomena observed with the Croton water the small amount of manganese in the Catskill water is probably the source of the manganese deposit on the wall of the Catskill aqueduct.

In the Journal of the American Water Works Association, volume 18, July, 1927, page 1, was described the work of C. A. H. Von Wolzogen Kuhr on Manganese in Water Works in Holland. It is there stated that the deposit of manganese dioxide takes place through the action of certain bacteria and certain mold growths and a special medium is described by which these bacteria were isolated after several months growth. They were obtained from both the water and the brown deposit. This special medium was made up at Mt. Prospect Laboratory and streaked with Catskill water and also from the brown muck. In many tests and after many weeks there was no evidence of any bacterial growth along these streaks causing a brown deposit of manganese dioxide. Certain molds which undoubtedly fell into the plates from the air during examination caused a brown deposit.

Cause of the Deposit.—It is our opinion that the manganese dioxide has been deposited from the water by the effect of absorption of alkali from the cement producing an alkaline reaction adjacent to the wall. This alkaline reaction is necessary for the reaction to take place and the inspection and analyses showed that the cement had disssolved from the surface of the concrete. Iron trioxide and alumina may have similarly been deposited from the water or their source may have been the cement.

It was at first thought that the deposit might be due to bacterial action, inasmuch as it was 1 in. thick prior to chlorination in the aqueduct near Ashokan and covered the entire area of wall exposed, whereas at the time of this inspection the deposit at the first point was in patches and only ½ in. thick and no new growth was noted until sampling point No. 4 was reached. Since there is no evidence of bacterial action and hence sterilizing effect of the chlorine, a possible assumption is that prior to chlorination the alkalinity produced by solution of cement from the surface was greater than at present, thereby producing a stronger alkaline reaction. Also that since chlorination the residual chlorine tends to neutralize any alkalinity produced in the upper portion of the aqueduct and that this action is lost below Newburgh.

The question of addition of chlorine at Newburgh to reduce the deposit below this point and possibly increase the flow of the aqueduct by 30 m.g.d. is still under consideration.

Innovations in Water Treatment

How Some Ontario Problems Were Solved

By A. V. DELAPORTE
Chemist in Charge, Experimental Station, Ontario Department of Health

THE removal of turbidity and bacteria has become so standardized, as to require no comment. Taste and color removal without excessive chemical treatment, give an opportunity for novel application of standard methods.

Taste is an elusive thing, and is in part a psychological problem. The delicacy of the perception of taste varies with each individual, and as the flavors of some surface supplies vary with the season, and the temperatures, the investigator is sometimes at a loss to correlate the data which he has collected.

Removal of Phenolic Taste.—The removal of phenolic taste from the Toronto water supply by super-chlorination and dechlorination, is, in the writer's opinion, the greatest innovation in recent years, of water treatment in Ontario. This accomplishment is due principally to Norman J. Howard. The process and results have been fully described by Mr. Howard in the technical press.

In the sanitary engineering division of the Ontario Department of Health, we have approached the same problem in a different manner. We had first to secure a yardstick for the measurement of phenols. We tried several different methods including the Folin & Dennis method, and the Gibbs method. At present we are using the Fox & Guage method with fair results. This method has one major trouble. The indicator is a diazo compound composed of sulphilanic acid and sodium nitrate. This decomposes readily, and must be kept on ice.

The next point of attack on the problem was the source of the taste-producing substance. We found that fresh domestic sewage carried phenol in appreciable quantities. (2) That the phenolic content of sewage increased with storage, phenol being one of the degeneration compounds of the proteins under anaerobic conditions. (3) That phenols were present in wastes from certain industries using coal or its by-products. (4) Water that had been in contact with certain grades of coal tar or oil, carried phenol. (5) That certain wastes from rubber industries carried substances that gave phenol reaction.

Having located a number of possible sources of phenolic pollution, the problem is the prevention of this pollution, and the elimination of the phenol from the water where prevention could not be undertaken.

Here, the advance has not been great. We have proved that phenols are readily oxidized by atomic oxygen. In the activated sludge process—by potasium permanganate, and by chlorination, or in the passage through a properly functioning slow sand filter. To date we have found no practical means of removing phenol by precipitation, absorption, or mechanical filtration, Organic tastes, which after phenol, cause most complaint, are really from three different sources. They are (1) from plankton, (2) from decomposing plankton, (3) from other decomposing organic matter. Some years ago, the writer reported treating the water supply at Richmond Hill with compressed air. It was very evident that a large portion of the taste-producing substances were either gaseous, or of a volatile nature. Continuing our observations at this plant, we found that fairly violent aeration in the mixing chamber caused a foaming. The air passing from the water had a strong marshy smell. The foam, which rose as high as 5 ft., on collection and settling was very similar to a septic effluent in appearance and odor. Chlorine in excess was tried instead of aeration, and gave good results, but not as good as the air had given; but a combination of the two gave really remarkable results.

The water supply of Burks Falls is very interesting. It has color, turbidity, taste, and is slightly acid. The supply is a gravity flow from Reazin Lake through mechanical pressure filters. Reazin Lake, the source of supply, lies in the wilderness about four miles from the town. The filtration plant is about one-half mile out of the town. All chemicals used in the treatment must be introduced under pressure. It was found that pumping a slightly alkaline solution of sodium hypochlorite into the main before filtration, accomplished complete removal of color, taste, turbidity, and acidity. The chlorine oxidized the iron and sulphides, which caused the color and taste. The precipitated iron acted as coagulant on the filters. A clear, colorless, tasteless effluent was obtained.

Color Removal at Dundas.—At Dundas, the problem was color removal without an excessive dose of alum. In order to remove the color successfully using alum only, sufficient alum was required to lower the pH value to the iso-electric point. Acid was used to lower the pH value with minimum dosage of alum without success. Aeration was tried, first in the settling tank, and then in the mixing chamber. The system was arranged after the manner of an activated sludge plant. The floc, as it settled out, was returned to the incoming water, with really excellent results. There were mechanical difficulties in the return of the sludge, which militated against complete success; however, in the remodelling and enlargement of this plant, aeration will be incorporated as a permanent fea-

ture, and the pre-treatment of the water will virtually consist of an activated sludge process.

North York has a periodic disturbance in the taste when there is a heavy run-off from the agricultural land draining into the source of supply. A strong strawlike taste develops. We have controlled this by maintaining a fairly high residual chlorine, and by the use of ferric chloride.

Smith's Falls secure their water from the Rideau Canal. Above the intake, there is a large area of drowned lands which had not been cleared before flooding. This area is a hotbed for the growth of equatic flora and fauna. The result is that the raw water for the town is an aquatic zoo. This summer, the plan is to control the taste temporarily with ferric chloride, and to experiment with aeration in an endeavor to reduce the chemical dosage.

The last experiment was carried out at Brampton last year. Brampton has an auxiliary supply from Snell's Lake. This water, highly charged with micro organisms, is filtered through Ransome drifting sand filters, and chlorinated. Last July, the odor from the filters in the pumphouse became very bad, and there were serious complaints as to taste. Pre-chlorination was resorted to as a temporary expedient. The odors were eliminated, and to a certain extent, the taste also. Even with a dose of 60 p.p.m. of chlorine for three days, we had no residual chlorine after filtration.

Bacteria on Leather Washers

Lactose-Fermenting Organisms Growing on Leather Washers at Chicago

By F. E. GREER and L. C. KELLS
Bureau of Laboratories and Research, Department of Health, Chicago

IN recent years water samples from various hand sampling pumps used to draw waters from the tunnels of the Chicago water supply system have shown unexpectedly high Bact. coli-aerogenes indices which were not explainable on sanitary survey and were not consistent with the current findings of raw Lake Michigan water or with water from other sampling pumps on the same tunnels. The first such instance of persistently high coli-aerogenes indices in a sampling pump occurred at the Lake View station and led to the discovery of an old abandoned sewer near the sampling point on the tunnel. However, after elimination of this possible source of contamination, the high coli-aerogenes findings still continued.

Investigation of Washers.—At a conference of Arthur E. Gorman and H. H. Gerstein of the water control division, with Dr. Fred O. Tonney and the writer representing the research laboratories, it was decided to investigate the washers along the lines reported by Sir Arthur C. Houston in connection with a similar problem arising in the London water works system. The washer was removed by Mr. Gerstein and brought to the laboratory, where it was placed in a mason jar containing 300 c.c. of sterile tap water and kept at room temperature. Examination of the water showed the presence of Bact. aerogenes in large numbers. In the course of a few weeks, the number of organisms had increased to 3,000,000 per c.c. At this point the water in the jar was drawn off and replaced by another 300 c.c. of sterile tap water. An initial drop in the count was again followed by an increase in numbers which soon reached millions per c.c. Repeated changes of water gave the same findings and the washer retained its ability to support growth of Bact. aerogenes for the two years it was under observation in the laboratory.

Following this experience, other investigations led to the discovery under similar circumstances of three examples of washer contamination with organisms of the coli-aerogenes group in the city water supply system. Replacement with new leather washers was in some instances followed by reinfection after a time and recurrence of the same condition. Of the four organisms found growing in the sampling pump washers, one was identified as Bact. coli, one as Bact. aerogenes, and two were classified as members of the coli-aerogenes group by the Standard Methods procedure.

Two leather washers collected from fire hydrants were also found to contain large numbers of coli-aerogenes organisms. Placed in sterile tap water, they developed increasing numbers, one reaching the total of 40,000,000 per c.c. This organism proved to be a typical strain of Bact. coli.

Four other washers from private wells in which high coli-aerogenes findings were not supported by the evidence of the sanitary survey, were found to contain lactose-fermenting organisms of the coli-aerogenes group and to support their continued growth in large numbers for a long period. In all four cases, removal of the infected washers from the pumps was followed by the disappearance of the coli-aerogenes organisms from the well water.

Brass Cylinder Pumps Substituted.—On the basis of this investigation, H. H. Gerstein of the water control division, recommended that all pumps containing leather washers be replaced by brass cylinder pumps. As soon as this was done, the abnormally high indices stopped. There was one exception to this, however, at the Springfield Avenue sampling point. Upon investigation it was discovered that a leak had developed in the new pump and that the engineer had repaired the leak with packing. When the packing was removed the Bact. coli disappeared. In the laboratory this packing yielded many thousands of Bact. coli even after repeated washings.

While these investigations were under way we became interested in the possibility of growing the various lactose-fermenting organisms found in water by experimental inoculation on leather washers.

For this purpose four new leather washers were soaked in alcohol for some time and alcohol gradually diluted with sterile tap water over a period of several days. Sterility tests made on the washers after one week showed no organisms that would grow aerobically or anaerobically on agar plates or in lactose broth.

Experimental Inoculation of Leathers.—Two of the washers were then inoculated with pure strains of Bact. coli and two with pure strains of Bact. aerogenes. The initial inoculum was about 1,000 organisms per washer. The organisms immediately began to increase in number and in a period of two weeks the washers containing Bact. coli showed 6,000,000 and 4,000,000 Bact. coli per c.c. while the washers containing Bact. aerogenes each showed 300,000,000 per c.c.

All of the washers, both those from the pumps and those experimentally inoculated, supported continual growth of the organisms in the jars despite the frequent washings and changes of water.

Another set of washers was inoculated with Bact. typhosus, Bact. aerosporus, Cl. welchii and Strep. fecalis. The tests were carried out as before. There was no increase in the number of these organisms on any of the washers. In the course of a few weeks it was not possible to recover any of the organisms from the water containing the leather washers; moveover, there was no over-growth by other organisms.

The washers which had been inoculated with strains of Bact. typhosus, Strep. fecalis, Bact. aerosporus and Cl. welchii were then immersed in alcohol and the alcohol gradually diluted with water over a period of several days. After they had been found sterile, the washers were inoculated with strains of Bact. aerogenes and Bact. coli isolated from sewage. All the organisms grew luxuriantly, notwithstanding frequent washings and changes of water.

A canvas washer impregnated with paraffin was inoculated with a strain of Bact. cloacae and studied under the same conditions as the leather washers. Bact. cloacae continued to grow for several months. After this time the washer was sterilized and then inoculated with a pure culture of Bact. aerogenes. This organism also multiplied at a rapid rate, notwithstanding frequent washings and additions of sterile water.

At the suggestion of W. F. Langelier of Leland Stanford University in a

letter to Dr. Tonney, reporting a slimy growth which he encountered in well water, we decided to include Bact. mucosus capsulatus in the series. A strain of this organism was therefore inoculated into washers. We obtained a typical slimy growth and the organism increased in numbers on leather washers over a considerable period of time. The possibility of growing coli-aerogenes organisms on leather washers in a continuous stream of water was next tried. The washers containing the organisms were placed in running tap water under conditions of continuous rapid flow, continuous slow flow and intermittent flow. On some of the tests the washers were dried and again tested as in the preceding experiments. In every case the organisms grew readily on the washers in the presence of flowing water. The growing of these organisms in mixtures on leather washers was next investigated. Bact. coli with Bact. mucosus capsulatus and Bact. coli with Bact. aerogenes were tested. All of these organisms grew readily in mixtures on the leather washers. Finally a new sterilized washer was immersed in treated sewage, containing approximately 100 Bact. coli and 50 Bact. aerogenes per c.c. and tested in the manner described. In all these tests the organisms grew and increased in numbers on the leather.

Stream Pollution

Pure Stream Movement Will Accomplish Its Purpose

By SCOTLAND G. HIGHLAND
Secretary and General Manager Clarksburg Water Board, Clarksburg, W. Va.

THE question of pollution of drinking water supply sources is of paramount importance, and we must go into the matter impervious to the pleas of commercialism, and with the determination, should persuasion fail, to carry it by petition to our respective legislatures.

With an increasing population has come an increasing need for good drinking water, and a decreasing available supply; rapidly growing towns and cities spill their filth into sewers that empty into the nearest water channel, while our multiplying industries seek the least expensive method of disposing of their waste. In this matter of steam pollution, however, those directly responsible for it, and we who supinely tolerate it are equally to blame for the crime.

Lack of Vision Basic Cause.—It is astonishing that there should be any opposition to the preservation of clean streams, yet the opposition is strenuous, founded partly on lack of vision, but mostly based upon selfish motives. A misleading argument of the opposition is that the pure stream movement is backed by sportsmen, and that it is an impractical dream; that the people are confronted by a choice between fish and industry. This contention is absurd, for not only fishermen, but all intelligent persons recognize the fact that the water of streams in which fish cannot live is unfit for human beings to drink, and that the preservation of human life is necessary for the continuance of industry.

Defilement of Streams Indictable Offense.—There is a great deal of ignorance among industrial heads about the legal status of stream pollution. There seems to exist a prevailing impression that the pollution of lakes and rivers is a perfectly natural, and even lawful custom in the absence of specific statutes prohibiting it. The contrary is true. Polluters, great or small, are law breakers. Many highly respectable offenders do not know that from the early days of common law, the defilement of streams has been an indictable offense when such defilement affects the public, and the right to restrain by injunction any one who corrupts water with industrial waste is a very ancient right.

Education is the Solution.—A better remedy, however, lies in the arousing and educating of our people to the gravity of the situation, and a special effort should be made to induce manufacturers and those connected with polluting industries, to give their personal thought and time to the investigation of present conditions. They are keen, level-headed men, and they do not take delight in poisoning the water needed by the people; in this age of terrific efficiency they have sought to keep down the expenses of operation by getting rid of the waste in the most convenient manner, with little if any thought about the result.

In years gone by, there was little complaint; our streams were numerous and full of water, our industries comparatively few, our population small, and under those conditions the water, most universal of solvents, could digest or carry away impurities. Our streams can no longer do this, and if the industries do not realize this fact it is certainly time that they were told it.

Many of those who are engaged in industries that pollute water are citizens of the finest type, as proud of their community, state and country, as the rest of us, but much missionary work must be done among them, where one convert will count as many missionaries.

Industrial Chemists Problem.—Practically every business involves problems that must be solved in office or laboratory. It is not the duty of the water utilities nor of the state to conduct experiments for the solving of the waste disposal problem for the hundreds of industries within its bounds. The cost of maintaining a corps of skilled chemists would be prohibitive, but every plant, or particular industry is forced to employ the best engineers and chemists in its special field. These experts are best fitted to deal with and solve this problem, and a definite co-operation of one with all, would reduce the cost of experimentation to a minimum sum, which, when apportioned would not bear too heavily upon any one of the numerous enterprises affected. It is but just that the expense of experimenting should be borne by those who are making money in the offending industries.

Using Water Courses as Sewers.—The only duty devolving upon the state is that of telling big and little business, individuals, communities, hamlets, villages, towns and cities that they can no longer use the streams as sewers, and that they must take prompt action in otherwise disposing of their waste product. Experience thus far shows that, unless forced by law or a supervising state agency, industries will not change their present life-destroying methods, but although the task of converting the manufacturers and other polluting groups may be difficult, compensation is to be found in the rapid progress now being made in educating the rest of the community to vigorous and incessant protest that will result in legislative action in the matter.

Accept the Inevitable.—The pure stream movement is based upon the primal law of "the inalienable rights of the people"; it will accomplish its purpose, and unless the polluters accept the inevitable, take the initiative and show the people a commendable willingness to clean house, an indignant public may demand legislation of so drastic a nature that real industrial harm would ensue.

Far Afield for Drinking Water.—Many cities have had to go far afield for their supplies, as the capacity of wells, adjacent stream or lake, became inadequate to meet the demands of the community, but very often it was the pollution of the local supply that made necessary the seeking of more distant sources.

Far Afield for Drinking Water.—Conspicuous examples of such cities are: Los Angeles, which brought her new supply from 235 miles away; San Francisco, 154 miles; New York, 120 miles; Tulsa, Oklahoma, 60 miles; Phoenix, Arizona, 32 miles; Butte, Montana, 27 miles; Denver, 25 miles, and Norfolk and Portsmouth, Virginia, about 20 miles each.

Winnipeg, Canada, brought her new supply a total distance of 98 miles, while Victoria went 38 miles for water.

In Australia the Coolgardie pipe line is 351 miles in length, and in southern Italy, the Apulian Aqueduct, constructed in 1924, to supply 266 communities, comprises 152 miles of main conduit, and 841 miles of main and subsidiary branches leading therefrom.

Self-Preservation the Issue.—In view of the enormous expense incurred by carrying water such distances, an expense which the people at large must bear, it seems incredible that they have ever tolerated the corruption of nearer

supplies of something essential to the preservation of their lives.

Experience is not only a hard, but a very costly teacher, but the growing agitation over the pure stream question, will be the means of protecting the fledgling cities of today, and those of future years from the gross wrongs inflicted on us by the pollution of drinking water supplies.

Water Borne Treponema Pallidum.—Investigations carried on behind the battle lines in Europe have modified, to a considerable degree, the opinion prevailing among physicians and sanitarians that no danger existed from the bodily discharges of persons infected with the deadly germ treponema pallidum. The danger is now quite generally recognized, and the fact that these germs will survive for a long time in sterilized water was announced by the eminent Dr. Roseneau as early as 1916. Water pollutes itself from what is washed.

Colloids in Water

Effect on Turbidity and Color

By C. H. CHRISTMAN
Filtration Department, National Aluminate Corp., Chicago

WE are all more or less familiar with turbid waters which will not settle completely on long standing. The existence of coloring matter in colloidal condition has also been noted. Careful filtration of a raw water fails to remove some of this turbidity and color, and it is with this material that our interest centers at present. We are familiar with the fact that some waters can be efficiently coagulated with a minimum of chemical while others require many times this amount to secure the desired results. In some instances this condition may be due to the nature of the dissolved material, yet in others there seems to be a relationship between the nature of the suspended matter and coagulating dose. Some waters require very careful regulation of pH to secure good coagulation and in other instances this control appears to be unnecessary. In addition to matter which finds its way into water naturally, pollution from domestic and industrial sources add to the colloidal content of water.

It may be stated definitely that the presence of a colloidal condition in raw water does not mean that matter, so present, is organic or inorganic, from natural sources on a water-shed or from pollution. It may be from any or all of these sources. A colloidal condition indicates that matter of some type is present, not in true solution, yet in a state of sub-division in which the particles are separate entities, though submicroscopic in size. In fact, we believe that matter of vegetable and inorganic origin may occur in colloidal condition. With colloids resulting from pollution as well, it follows that each type will present a problem in itself when we consider the removal of the colloid by coagulation.

Differentation of Colloids. — Our knowledge of colloids and their characteristics indicates that some are acid, some neutral and some alkaline in character. Their reaction in an electrical field may be used to differentiate them into charged and uncharged colloids. It does not indicate whether they are of organic or inorganic origin. For this study, it is necessary to concentrate them by ultra-filtration through a suitable membrane and study them further. By connecting a battery or other source of direct current to electodes in a U-tube which contains a colloidal water, migration of the colloid occurs and coagulation may be observed at the electrodes. A critical study of this particular phenomenon should lead to the development of fundamental data which might be of importance in answering some of the problems relating to coagulation.

The present report must be considered as preliminary, in that phases of the study have not been completed. It is presented, however, with the hope that it will arouse the interest of others, precipitate thought and discussion, toward the end that our common knowledge of colloids in water supplies may be increased.

We have been concerned in particular with the occurrence of colloids in water, their prevalence, the nature of any charge they carry, their migration in an electrical field, the neutralization of the electric charge carried and its effect upon the existence of the colloidal state, the extent of the charge carried, any relation between colloids and pH, the existence of an iso-electric point or optimum pH at which they can be coagulated, together with such supplementary data as might be gleaned in the course of a study such as this.

Use of Ultramicroscope.—For this investigation, use has been made of an ultramicroscope. The cataphoresis cell contains the sample under investigation. It is provided with stopcocks for filling and draining. A capillary tube with a 1 mm. opening connects the two reservoirs, in which the platinum electrodes are sealed. The distance between the electrodes is 15 cm. The electrodes are connected to radio B batteries to assure sufficient voltage for migration rate studies. pH values were determined by colorimetric methods.

In using the ultramicroscope, water is placed in the cell with the level above the top stopcock. This is closed to prevent movement of the water during observation. A very strong beam of light is directed through condensing lens and upon the water perpendicular to the axis of observation. In this manner it is possible to observe the manifestation of a colloidal condition. The rays of light passing through the water strike a colloidal particle and are diffracted. This condition may be observed, for it is similar in character to the effect of a beam of sunlight in a dusty room. The individual particles, otherwise unseen, become apparent when light is reflected from their surfaces. Finding this condition in a raw water, we proceed to estimate the extent of the colloidal condition. This has been empirical thus far, but in future work it is planned to combine dialisis studies with the ultramicroscopic examination so that quantitative data may be available. Next, the cell is connected to the batteries and observation made to note migration of colloidal particles. If migration is observed, the direction of current flow is reversed to ensure that migration is due to the current rather than to movement of particles with water flow. In this manner we have observed particles flowing with the negative current toward the positive electrode.

Charged Colloidal Particles and Coagulation Requirements.—It has been our belief that colloidal particles which are charged might carry more or less of the electrical charge and this condition might be correlated to the coagulation requirements of the water. If the particles vary in the amount of their charge, attraction to an electrode under a constant current flow should vary and their rate of migration should be proportional to the charge carried. Ellms reports the measurements of colloids in Ohio River water as 0.29 centimeters per hour with a potential gradient of 4 volts per centimeter. The ocular of the microscope used in this work is fitted with a graduated scale. Movement of the colloids across this scale were observed and the time required for the movement across a measured distance was checked by a stop-watch. Observations were repeated and average values were obtained. It is worth noting that most of the samples showed little variation in the rate of migration, while some few gave wide variations. In this manner data were secured which rate the samples in terms of migration per centimeter per second per volt.

The samples were raw waters which were received in our laboratory for analysis. Coming from all sections, a wide variation in samples might be expected. The possible relation of other analytical data to the colloidal condition will be studied further and will be presented in a future report.

Colloidal Particles Charged with Electricity.—We have found that the colloidal particles in the raw waters studied are charged with electricity, the charge is negative in character, the rate of migration of colloidal particles induced by direct current varies and this variation is a function of the amount of charge carried. There seems to be no generic relation between the rate of migration and pH of the raw water.

Dispersion of colloids results from the similarity of charges which the particles carry. Neutralization of these

charges, by any methods, will remove the condition which prevents the coagulation of these colloids. The effect of the electric current has been demonstrated and is being tried on a plant scale at one of the larger plants in the west. The coagulants used in general practice give a colloidal condition under certain conditions and it is known that these colloids are positively charged. Thus, when colloids of opposite charge are mixed, there is mutual neutralization and precipitation. The effects of various colloids and the different coagulants are being investigated. It is possible that this will lead to the use of specific treatment for certain water conditions, giving better operation, greater control and improved water.

Water Treatment for Industrial Use

Recent Developments in Boiler Operation and Their Influence on Feedwater Treatment

By SHEPPARD T. POWELL
Consulting Chemical Engineer, Baltimore, Md.

LOCAL conditions have a marked influence upon feed water problems everywhere, yet fundamental knowledge on the subject of water conditioning is the foundation upon which the solution of the problem ultimately must rest. This conception of water treatment for industrial use now seems to be quite general among American engineers responsible for the safe and economic operation of steam generating equipment. Much time and effort has been expended in attempting to establish and carry forward broad fundamental research. As a result of such effort, at least two important investigations have been tentatively arranged. These are study of the mechanism of priming and foaming of water under steam conditions and the determination of the hydrogen ion concentration of concentrated boiler water under steam conditions. The necessity for such research is clearly apparent and the result of these studies should do much to improve our knowledge of two of the most perplexing problems in steam boiler operations, i. e., wet steam and corrosion of boilers and appurtenances.

It is difficult to justify a specific list of new appliances or processes in this or other fields without creating useless controversial discussion. We shall not attempt therefore, to do more than direct attention in a general way to indicated trend of developments.

The Most Recent Development.—Possibly the most interesting recent engineering development in feed water treatment has been the combination of various forms of water purification processes. The combination of chemical and zeolite softening, additions of coagulants with softening reagents, continuous blow-down system and steam purifiers has revolutioned feed water treatment. This has made possible a broader field for the designing engineer than previously was considered possible.

The conditioning of feed water is no longer limited to a single process but a series of corrective treatments. The arrangement and extensiveness of the design will depend upon the steam station requirements and economy resulting from the combination treatment. Recirculation of concentrated boiler waters has been used in the past but has not been widely employed. Recently a number of novel applications have been made which are attracting attention since they have some merit for specific conditions. In some of the designs recirculating only with heat recovery is effected while in others partial softening also takes place.

Increased Use of Softening Reagents.—No new chemicals of importance have been produced for water conditioning but there has been a very marked increase in the use of some softening reagents. This is particularly so in the case of phosphates and sodium aluminate. The increased use of the reagents is due primarily to purer products and more exact knowledge of their value for specific conditions. The investigations to determine methods of water treatments to inhibit embrittlement of boiler steel have been partially responsible for the increased use of phosphate. Both di and tri sodium phosphate have been used in the past. Mono phosphate has been now offered for this service. This product has some advantage over the other sodium salts since the desired soluble phosphate is obtained with a lesser concentration of the sodium radicle.

Electrolyte Methods.—Inhibition of corrosion of boilers, heaters and condensers by electrolytic methods has continued to attract attention and a number of successful installations have been made during the past few months. Research work has been conducted at at least two universities in an effort to determine the cause of this phenomenon. A number of theories have been advanced to account for this form of protection but experimental data is lacking which would account for the mechanism involved in the retardation of the corrosion rate.

A number of valuable contributions to the art of industrial water treatment have been made recently. Possibly the most constructive study in reference to the mechanism of scale formation has been the work of Dr. E. P. Partridge, conducted at the University of Michigan. The data presented by this investigator have thrown new light on deposition of scale forming solids and should prove of value in directing attention to future methods for controlling scale formation in evaporators and in boilers. Similar work is to be carried on by others along the same general line as pointed out by Dr. Partridge. The results of this work will be awaited with interest, since it may lead to revolutionary ideas in reference to the fundamental idea of scale growth.

The recent corrosion study by Dr. R. U. Evans has added much to our knowledge of film formation and the inhibition of corrosion by this action. Although this work is not a specific study in boiler water treatment, the scientific facts established have great application to the control of corrosion problems encountered in steam generation.

A number of very valuable contributions relating to embrittlement of boiler steel have been made through the Verein Deutscher Ingenieure. Likewise, the work of *Thiel and Luckman on the same subject will be found instructive in reference to German investigators' viewpoint on this important problem.

Many New Problems Encountered.—Many new problems have been encountered, which may not be solved without more intimate knowledge of the chemistry of water. The presence of non-condensible gases in steam, especially carbon dioxide, has given much concern to those responsible for steam station control. Acid steam from this source is much more frequent than is usually suspected. No solution for the control of the difficulty is at present available. The disassociation of even pure water in steel economizers, and superheaters has been shown recently to be a potential possibility under certain conditions. The detrimental effect on steel, from such disassociation products, is well known and must be avoided since the resulting damage is permanent and may be very costly. The problem may not be discussed intelligently since much study must be given to it over a wide range of conditions before the extent and acceleration of this destructive action on steel can be determined accurately. The report on this subject by Mr. C. H. Fellows to be presented at this meeting shows the potential possibilities of the disassociation of water. One industrial concern is now conducting similar experiments at pressures up to 4,000 lb.

The aim of this group to solve these numerous problems by cooperative effort has been recognized as a constructive program, to accomplish the desired results with the least duplication of effort. The influence of this movement has attracted attention from similar European groups and tentative plans have been arranged to have exchange of ideas with at least one of these cooperative research associations. International exchange of ideas leading toward the solution of these problems should be mutually beneficial.

There must necessarily be more or

*Committee report on feed water studies of the Association of Large Boiler Manufacturers.

less lost motion in carrying forward any cooperative work of this kind. There are so many specific problems that are peculiarly important to each group that it is not possible to confine the work of these committees to any specified plant control measures. The most that can result from the effort of this work is to establish fundamental concepts and to arrange these data for practical use. With a clear understanding of the problem based upon established facts as to the cause or causes of the specific phenomena, corrective treatment is fairy well assured.

Selecting Pumping Equipment

Some of the Broad General Principles

By A. P. PIGMAN
American Water Works & Electric Co., New York

THE engineer in selecting equipment for a pumping station may be confronted by an almost infinite variety of situations. Any fixed rule drawn from the solution of one problem is almost sure to be misleading in the solution of the next. Yet, in order to shorten his task and to make it more more nearly certain that the solution of each problem will be very close to the best solution possible, it is desirable that we discover, if we can, some broad general principles for his guidance.

Situations to Be Met.—In classifying situations to be met, we have to consider a great variety of things, such as the purpose of the installation—whether a new plant is to be built, or additional capacity added to an old plant, or more efficient equipment added to an inefficient plant. We have to consider the character of the service—whether it is to be single pumpage, double pumpage, or a combination of single pumpage with a ground water supply. The load may be uniform and vary only seasonably, or there may be wide daily fluctuations, superimposed upon seasonal fluctuations, and even the head may vary, especially when fire pressure must be raised. Finally, water works plants may vary in the quantity of water pumped and the head pumped against all the way from small stations requiring only 2 to 3 horsepower to large stations requiring thousands of horsepower. The variety of circumstances is almost without limit.

Table I

		Bhp.
Group 1		
	Average Load	above 1200
	Typical Plant av. load	1600
	Typical Plant max. load	2000
Group 2		
	Average Load	600-1200
	Typical Plant av. load	800
	Typical Plant max. load	1000
Group 3		
	Average Load	250- 600

		27,500	20,000	17,600

Classification of Types of Equipment.—To meet these situations, there are many types of pumping equipment, but at least one simple classification of these can be made based on the source of energy used for driving the pumps. Practically all pumping plants are operated either (1) by steam generated at the plant, or (2) by internal combustion engines, or (3) by electric energy purchased from the local power company.

Using a size classification based on the horsepower required to operate a plant, I have taken four typical plants and have made a comparison of the annual cost, including fixed charges on investment, of operating each of these four typical plants, first, with steam equipment, then with Diesel power and, finally, with purchased energy. Four series of studies are made of these four sizes of plants each using the 3 types of drive, steam, Diesel, and electric.

In the first series of studies it is assumed that the water is pumped only once; that is to say, the plant pumps either all raw water or all clear water. It is further assumed that there is a large reservoir in the system, so that the load is uniform, varying only seasonally. Finally, it is assumed that the problem is to build an entirely new plant. The 3 types of pumping equipment are fitted into this situation for each of the four sizes.

After this first series of studies, a study is made of the effect of double pumpage being substituted for single pumpage. Then the effect of a fluctuating load is investigated and, finally, the problem is reviewed in the light of merely adding new capacity to an existing plant rather than building an entirely new one.

Pumping stations have been divided, more or less arbitrarily, into four groups (see Table I) based on the brake horsepower required to carry the average load. For each group, a plant requiring an average horsepower somewhere near the middle of the group is taken as typical.

As a working basis in all of these studies, the cost of coal is taken to be $3.00 per ton, the cost of Diesel engine oil 6 ct. per gallon, and the cost of electric energy including demand charges, 1 ct. per K.W.H.

Summary of Four Typical Cases.—1. When a new plant is to be built for single pumpage at a nearly uniform rate a steam plant will usually be the most economical provided the load is sufficient to call for turbines of more than 1,500 horsepower capacity. (See Table II.)

2. For similar plants with loads averaging less than 250 horsepower the electric plant will ordinarily be most economical but, if the power rates are high, the Diesel plant will be better.

3. In between these the field is highly competitive for the three types of equipment with the Diesel having ordinarily a slight advantage which tends to give way to the steam plant in the upper ranges and to the electric plant in the lower ranges.

We next consider the effect of pumping the water twice instead of once in each of the four cases. It is assumed that first raw water is pumped against a head of 50 ft. and that clear filtered water is pumped against the remaining 250 ft. It is suggested that for each of the three types of equipment the low service pumps and pit will cost approximately the same for in the case of the steam plant or the Diesel engine plant the most economical arrangement is to have small centrifugal low service pumps driven either by water turbines or electric motors, taking the energy either from water pumped by the main high service unit or from a generator driven by that unit. The added cost for the extra equipment in the case of the steam and Diesel plants beyond what would be added for the electric plant will be small amounting to about the following:

	Investment	Fixed Charges
Group 1	$15,000	$2,250
Group 2	10,000	1,500
Group 3	6,000	900

Obviously this is not enough to appreciably affect the relative standing of the three types of equipment in the three cases.

Fluctuating Load.—If the plant to be built is to have a fluctuating load instead of merely seasonal variations, the effect on the results obtained in the first series of studies is considerably more marked. The three series of studies considers this situation and assumes that the load fluctuates sufficiently for

Table III

		Uniform Load	Fluctuating Load	New Unit Added to Old Plant
Group 1	Steam	89,000		
Av. Load	Diesel	114,900		
1600 Bhp.	Electric	133,800		
Group 2	Steam	61,000	71,500	47,100
Av. Load	Diesel	62,700	70,200	55,600
800 Bhp.	Electric	71,500	79,800	70,600
Group 3	Steam	44,600	52,600	33,400
Av. Load	Diesel	35,900	40,200	34,200
400 Bhp.	Electric	37,800	39,700	37,800
Group 4	Steam	27,500		20,900
Av. Load	Diesel	20,000		17,900
160 Bhp.	Electric	17,600		17,200

the maximum load to be twice the average. The effect is shown in the second column of Table III.

The average load has remained the same, hence fuel and labor costs have remained the same. This may not be strictly true because due to the greater fluctuation in load equipment cannot be kept operating at all times in the regions of best efficiency, but, if the nature of the load has been carefully studied before hand and the equipment carefully selected, there need not be very much loss.

The peak load being 60 per cent higher, 60 per cent more equipment and hence 60 per cent more investment is needed. This influences adversely the steam and Diesel plants where fixed charges represent the largest portion of the total. Thus we find that steam and Diesel plants have lost some of their advantage in the two larger groups and that the electric plant takes first place in the third group and increases its lead in the fourth group.

Adding Equipment to an Existing Plant.—The fourth and last series of studies assumes that instead of building a new plant the problem is to add more capacity to an existing plant. (See Table III.)

Here the effect on the original four studies (see column 3 of Table III) is exactly the reverse of the effect of a fluctuating load. Again the fuel cost has remained unchanged but since no duplication of equipment has to be provided for, the amount of equipment needed is less and hence the plants which require large unit investments are benefited. We find now that in group 2 the steam plant has gained a considerable advantage and even in group 3 it now shows the lowest annual cost. Even in group 4 the cost of Diesel oil need only go to 8 ct. and of electricity to 1 1/3 per KWH. for the steam plant to show up as well as the other two.

If the added capacity is for meeting peaks only the Diesel or electric plant may regain their advantage over the steam plant.

Even if new capacity is to be used for regular service the steam plant should not be given the full advantage indicated by the third column of Table III if the existing equipment which will serve as standby is old and in bad shape and will have to be discarded in a few years.

There are many small plants smaller than the typical plant of group 4 pumping a million gallons per day or less where for the sake of convenience alone an electric plant may be justified even at a slightly higher cost since the amount involved cannot be great.

Reciprocating Pumps.—In all four studies the steam plant has been worked up on the basis of turbine drive. In the two large groups a reciprocating pump is practically out of the question but in the two smaller groups there will be occasions where the highly efficient crank and fly-wheel pump will make as good a showing as turbine driven units. Since, however, in the building of new plants a steam plant can generally be justified only in the larger sizes, this means that the installation of new reciprocating pumps is practically limited to a portion of the cases where steam equipment of any kind can be justified in making additions to existing plants. It is pointed out, however, that, where these highly efficient crank and fly-wheel pumps are in good operating condition and additional pumping capacity is not needed, there is no possibility of installing any other type of equipment for the purpose of reducing operating expenses.

General Summary.—We have passed in review a large variety of situations to be met in the installation of new pumping equipment. We have attempted to classify these situations and to show that under one set of circumstances one type of equipment generally had an advantage and in another set of circumstances another type generally had the advantage. Hardly anywhere, however, have we found that any type of equipment has an undisputed field. Even in the cases where one type of equipment seemed to have the greatest advantage over the others, our analysis showed that a change from what might be considered an average in the cost of coal, of oil or of electric energy, would make another type more suitable.

In general we found that for a new plant having a uniform pumpage rate a steam plant generally had quite an advantage, provided the plant was large enough to justify the installation of a turbine of more than 1,500 horsepower. On the other hand, if the horsepower required were less than 250 or 300 the electric plant generally had an advantage. In between these sizes the Diesel plant had a slight advantage but was closely competitive with steam as the sizes approached the upper limit and with electricity as the sizes approached the lower limit.

We found further that whether the pumpage was single or double pumpage made very little difference.

We next found that if the load had wide fluctuations more equipment was required to handle the same average load and, therefore, the low unit investment of the electric plant was given a greater advantage than it possessed in the case of the uniform load and its field accordingly expanded.

On the other hand we found that if instead of building a new plant the problem were to add capacity to an existing plant the amount of equipment required to take care of a given load would be less and the steam and Diesel plants with their low operating costs would be given a greater advantage than they possessed where a new plant was to be built and the field of these plants was, therefore, expanded down into smaller sizes than otherwise.

Ground Water in Yellowstone and Treasure Counties, Mont.

The Department of the Interior announces a report entitled "Ground Water in Yellowstone and Treasure Counties, Montana," by George M. Hall and C. S. Howard, just issued. The report, which is listed as Water-Supply Paper 599 of the Geographical Survey, was prepared in cooperation with the state engineer of Montana, the department of chemistry of the Montana State College and the water laboratory of the Montana State Board of Health. It may be obtained from the Superintendent of Documents, Government Printing Office, Washington, D. C., for 25 cents a copy.

These two counties are traversed by the Yellowstone River, and on the lowlands near the river wells generally yield large quantities of water, although much of it is of poor quality. On the upland in many places the inhabitants have difficulty in finding adequate supplies of good water even for domestic use. A careful study of the geology has shown that in some places where the surface conditions appear to be unfavorable or where the water is of poor quality, good supplies may be obtained by drilling to deeper formations. The Geographical Survey report gives not only general descriptions of the rock formations but also more detailed discussions of the conditions governing the occurrence of ground water in each of the more than 100 townships that lie in the two counties.

The report contains data in regard to 100 wells, with analyses of water from them and other information in regard to the quality of the water. It also contains a geologic map showing the distribution of the rock formations, cross-sections showing the geologic structure and notes in regard to the unusual natural features of the region.

Activated Sludge Plant Operation in Great Britain

Experiments at Reading, England, Discussed in Paper Before Royal Sanitary Institute

By A. S. M. PARSONS
Borough Engineer, Reading, England

A GENERAL idea seems to have prevailed that the process is a simple biological one wherein a specific micro-organism oxidizes the impurities of sewage, and Dr. Calvert has cited the vinegar process as analogous to the popularly accepted theory. In this process, it will be remembered that a specific bacterium does in aerobic conditions actually oxidize alcohol to acetic acid.

In attempting to deal with some of the difficulties encountered in the activated sludge plant which has been installed for the Reading Corporation, the writer was forced to the conclusion that many of the empirical rules and ideas commonly adopted in the operation of such plants are not really generally applicable, and that the process cannot properly be described as simply biological.

The Velocity of Reaction.—In commencing the study of a reaction by physical chemistry methods, one of the first steps is, usually, to consider the velocity. The recation that is, of course, under investigation in the activated sludge process is the removal of the impurities in the sewage, and the results obtained can be most conveniently studied if plotted as a curve, the slope of which will indicate the rate of removal of the impurity, i. e., the velocity of reaction.

Since in their paper (Society of Chemical Industry, Jan. 3, 1927) Messrs. Butler and Coste referred to this instantaneous effect and considered it was appreciable, we endeavored to devise a critical experiment in order to show whether or not this was the case. The experiment was as follows:

Sewage was allowed to settle overnight and the supernatant liquid only used.

Into three 500 c. c. cylinders were placed:

1st cylinder—150 c. c. sludge (settled for one hour).

2nd cylinder—150 c. c. effluent from which the sludge had been settled.

3rd cylinder—150 c. c. distilled water.

Sufficient carefully mixed settled sewage was added to each to bring the total volume to 500 c. c., and the mixtures in the cylinders therefore consisted of 70 per cent sewage with (1) 30 per cent sludge; (2) 30 per cent effluent; (3) 30 per cent distilled water. The cylinders were each turned over twice thoroughly to mix the contents, allowed to stand for one hour, the supernatant liquids poured off and examined, with the following results:

Experiment T29
*Oxygen absorbed in three minutes; parts per 100,000

	1	2	3
	30 per cent sludge	30 per cent effluent	per cent distilled water
Results found	1.42	1.56	1.46
Results calculated	1.60	1.60	1.47
Difference—			
Instantaneous effect	0.18	0.04	0.01

The sludge for the experiment was in excellent condition for clarification, and it is to be noted that the liquids were not filtered, but were settled for one hour. There was a small amount of fine suspended matter (sludge particles) in the effluent used in No. 2.

The "instantaneous effect" is seen to be slight, and we venture to suggest that the results obtained by Messrs. Butler and Coste were due to the fact that their mixtures were filtered. The experiment does, however, show that even if sludge is allowed to fall but once through sewage, there is some removal of impurity as could very well be predicted from our knowledge of adsorption effects or of the action of enzymes.

The next point which must strike the observer is the enormous rate at which the three minutes oxygen absorption figure drops.

First Action in Process.—Examination of the effluent reveals that clarification has been achieved by the time the oxygen absorption curve flattens out to an approximately horizontal line, and it has been asserted on many occasions that the first action which normally occurs in the activated sludge process is clarification or the removal of colloids. Whilst objections have been advanced against this opinion, the following considerations seem to us conclusive:

1. The process may be interrupted at the point when clarification is achieved, and before little or any nitrates or nitrites are found.

2. Only an abnormal sludge, prepared usually by very prolonged aeration without sewage will nitrify first, but such a sludge will fail to clarify.

3. A sludge which will clarify well, but will not nitrify can be produced in two or three weeks, whilst the preparation of a nitrifying sludge requires a much longer time.

4. The Birmingham flocculated sludge process is a large scale demonstration that clarification is a distinct process, and is the first stage of the activated sludge process.

Three Distinct Stages.—That there are distinct reactions or "sections" in the process was recognized by Ardern and Lockett in their original paper (Society of Chemical Industry, May 30, 1914), but neither of these workers nor others seem to have pursued their studies very far in this direction.

Consideration of these and many other points has led the author to the conclusion that in the activated sludge process at least three distinct stages must be recognized:

1st stage—Clarification.

2nd stage—Reactivation or restoration of the powers of clarification.

3rd stage—Nitrification.

Stages 2 and 3 may go on simultaneously, and whilst stage 2 is absolutely necessary for the maintenance of stage 1, stage 3 is not necessary.

Granted the correctness of the foregoing deductions, the writer ventures to submit the following notes upon the first or clarification stage.

The Clarification Stage.—The term "Clarification" must be understood to signify not only the removal of colloidal matter, but also removal of some substances from true solution, as well as, of course, any matter in actual suspension, This use of the term is, of course, similar to its use in describing the clarification test modified by Fowler and Ardern for the approximate estimation of colloidal matter in sewage.

It has been said that the clarification of sewage when it is agitated with activated sludge may be due to:

1. A scrubbing effect.

2. Combustion or combination of the impurities with oxygen.

3. Induced combustion brought about by catalytic action of the activated sludge.

4. Biological action, including (a) carbonaceous fermentation, (b) proteolysis, (c) direct cell action.

5. Physical action, such as absorption of the impurities in or upon the sludge.

6. Combinations of some of these actions.

Let us deal with these statements in turn.

Scrubbing.—It is difficult to understand what is meant by "scrubbing" in this connection. One supposes it may

*The three minutes oxygen absorption figures for settled sewage and effluent were 2.10 and 0.42 respectively, and the calculated results in the above table are arrived at from these figures.

be intended to convey the idea of more or less violent interfacial contact. Quite how this could affect purification is not clear, but in any case the writers have never seen any arguments adduced that carry the suggestion very much further.

Combustion: Induced Combustion.—If clarification really is combustion either with or without the aid of catalysts (and enzymes are catalysts) then it follows that oxygen is necessary for the combustion. This being so, oxygen must be obtained either from solution (that is, from the atmosphere or applied air) or alternatively is stored up in the sludge during reactivation.

This point can be studied experimentally, but while it is a simple matter to investigate the reaction when atmospheric oxygen is excluded, it is not so easy to eliminate all oxygen or oxidizing agents from the sludge while retaining its active character. On the other hand, examination of the sludge does not reveal any large store of free oxygen, the presence of nitrates or nitrites being immaterial since clarification can quite well (or perhaps even better) be performed by a sludge which is incapable of oxidizing ammonia.

Clearly if clarification is a combustion process, it could not occur to any appreciable extent in the absence of aeration, and the following experiment was undertaken to prove that aeration is not essential:

Experiment to Prove that Aeration is Not Essential.—Sewage was used which had been settled overnight to remove all but the finer suspended matters. The activated sludge used was in good condition, and had been thickened by settlement for one hour.

To separate quantities of the settled sewage sufficient sludge was added to give the proportions stated below.

Series A was performed in bottles two-thirds full only, and the stoppers were removed from time to time to slightly renew the air.

Series B was performed in completely filled and well-stoppered bottles; no air being admitted.

The bottles were all shaken by hand for one hour, the aim being to keep the sludge from settling and on the move all the time.

At the end of the one hour of agitation all were settled one hour, the supernatant liquids were decanted off, and the effluents examined.

Oxygen Absorbed in Three Minutes, Parts per 100,000 Settled Sewage 1.78

	A (aerated)	B (not aerated)
5 per cent sludge	1.40	1.58
10 per cent sludge	1.34	1.38
15 per cent sludge	1.14	1.32
20 per cent sludge	1.04	1.20
25 per cent sludge	0.94	1.28

The experiment shows that whilst air assisted and improved the action, the clarification stage can go on in the absence of aeration.

Experiment No. T.49.—Experiment T.49 is a variation of the above, but in this experiment, whilst series A was agitated in 500 c. c. cylinders by means of compressed air from an open glass tube, series B was agitated by gently inverting, shaking, and swirling in stoppered bottles. In this case, instead of different amounts of sludge, the sewage was diluted to different extents by means of distilled water.

Sewage settled overnight was used, and the mixtures were agitated or shaken for half an hour, then settled for one hour.

Three Minutes Oxygen Absorption, Parts per 100,000*

	Calculated figures for mixture excluding clarification	Observed figures Series A (Aerated)	Series B (Not aerated)
Settled sewage, plus 10 per cent sludge	1.75	1.44	1.48
67.5 per cent settled sewage, plus 22.5 per cent water, plus 1 per cent sludge	1.33	0.98	1.08
45.0 per cent settled sewage, plus 45.0 per cent water, plus 10 per cent sludge	0.90	0.62	0.70
22.5 per cent settled sewage plus 67.5 per cent water, plus 10 per cent sludge	0.48	0.38	0 42

Again it is shown that clarification takes place in the absence of air, but is improved by its addition.

The experiments just quoted do not, of course, rule out the possibility that there may be a store of some oxidizing agent in the sludge itself, but the fact that nitrates or nitrites need not be present while clarification is taking place almost eliminates them from the problem. If there is an oxidizing agent present in the sludge it has not been identified. There is not, however, any evidence (so far as the writer is aware) that any really extensive amount of oxidation does not take place at this stage.

Buswell, in experiments on the relative importance of oxygen and stirring, concluded that stirring is more important (in the clarification stage) than oxygen, and that activated sludge will function at oxygen levels so low that they can scarcely be measured.

It may be accepted then that although aeration during clarification may help, it is not essential to this stage.

Carbonaceous Fermentation. — This term has been much used and signifies the conversion by bacterial agencies of complex carbon compounds into simpler carbon compounds with evolution of carbon dioxide or other gas, the process being analogous to true fermentation. The evolution of the gas is essential to the action.

There is at present little, if any, evidence of such action during the clarification stage. This is borne out by Messrs. Crawford and Bartow, who, in 1916, at the University of Illinois, found that the carbon dioxide content of the effluent air remained low for two or three hours, after which it considerably increased, and they conclude by saying: "Strong bacterial action does not take place for the first few hours." It is possible that fermentation may take place with more or less vigor at later stages.

*The three minutes figures for settled sewage and effluent from sludge (interstitia liquid) were 1.88 and 0.56 respectively.

Proteolysis.—While there may be some slight hydrolysis of proteins during clarification, it seems unlikely that there is any extensive splitting of proteins during this stage.

The albuminoid nitrogen elimination curve certainly follows very closely the three minutes oxygen absorption curve, but since there is in the ultimate result an accumulation of albuminoid nitrogen as represented by surplus sludge, hydrolysis or destruction can only be slight. Again when, under usually anaerobic conditions, hydrolysis of proteins (i. e., putrefaction) does occur, there is generally (if not invariably) production of ammonia, and were there extensive hydrolysis of proteins at this stage there would almost of necessity be an increase of ammoniacal nitrogen.

In practice, however, there is no increase of ammoniacal nitrogen in the clarification stage, but rather (if the sludge is capable of nitrification), a diminution, from which it follows that if there really is hydrolysis of proteins at this stage, it must be assumed that the ammonia produced (and the alkalinity resulting), must be removed or destroyed as quickly as produced.

Direct Cell Action.—In regard to the suggestion of direct cell action, i. e., absorption of the impurity through the cell walls of living micro-organisms, a few observations may be given.

Direct cell absorption would be by osmosis if bacteria are the micro-organisms operating. It is thus extremely unlikely that colloidal matter could be absorbed directly into the cell, although it is true that the living cell could, and probably does, absorb matters from true solution, but enzymic action would be necessary before the colloidal matters were broken down to a suitable condition for direct absorption. If bacteria are responsible for clarification, it should be possible to prepare the enzyme they secrete, and the enzyme (or enzymes) could be expected to perform the work in sterile conditions and in the absence of the bacteria.

Any action involving catalysis or enzyme action, removal, coagulation, or even presence of colloidal matter; or any action involving great areas of surfaces, may often with advantage be examined in the light of our present knowledge of adsorption, the mathematical theory of which was worked out by Willard Gibbs and independently by Sir J. J. Thomson, and may be stated in the form of the adsorption equation.

When—

X = the amount of substance removed (by adsorption).

M = mass of adsorbent in grams (really area of surface is the factor involved).

C = the equilibrium concentration, i.e., the amount of substance left.

a = a constant for the substance being removed.

n = a constant for the adsorbent.

$$\frac{X}{M} = a C^{\frac{1}{n}}$$

or $X = aM\sqrt[n]{C}$ or in words:

The amount of substance removed by unit quantity of an adsorbent varies according to:

1. The nature of the substance being removed.
2. The adsorbent employed.
3. The nth root of the equilibrium concentration. The value of n is usually between 2 and 10.

Since the amount of substance removed depends upon the nth root of the equilibrium concentration, adsorption reactions are much less dependent on initial concentration than ordinary chemical reactions, and adsorption goes on quite effectively in very dilute solutions; in fact, the adsorption equation is only accurate for dilute solutions.

Experiment T.48.—Sewage had been settled overnight.

Into separate 500 c.c. cylinders were placed the following mixtures:

(a) 25 c.c. sludge plus 25 c.c. interstitial effluent plus 450 c.c. sewage.
(b) 50 c.c. sludge plus 450 c.c. sewage.
(c) 50 c.c. sludge plus 337.5 c.c. sewage plus 112.5 c.c. 22½ per cent distilled water, 10 per cent.
(d) 50 c.c. sludge plus 225 c.c. sewage plus 225 c.c. distilled water.
(e) 50 c.c. sludge plus 112.5 c.c. sewage plus 337.5 c.c. distilled water.

The mixtures in the cylinders were then agitated by means of a slow stream of air bubbles sufficient only to keep the sludge from settling, but avoiding aeration to any extent. The bubbles were admitted through open-ended glass tubes of about the same diameter, and each supply was adjusted to about two bubbles per second.

After half an hour of agitation the air supply tubes were removed, and the sludge allowed to settle for one hour, at the end of which the supernatant liquid was decanted off and examined.

Oxygen Absorbed in Three Minutes—Parts per 100,000

Settled Sewage 3.02 parts per 100,000.
Settled Sewage after "Clarification Test" 2.16 parts per 100,000.
Effluents after half-hour agitation and 1 hour settlement.
10 per cent sludge with various dilutions of settled sewage.

	O Abs. in 3 min. C	Log. 10C.	Amount removed X	Log. 10X.
(a) 90 per cent S. S., 5 per cent interstitial water, 5 per cent sludge	2.52	1.4014	0.50	1.0000
(b) 90 per cent S. S., 10 per cent sludge	2.14	1.3304	0.88	.9445
(c) 67½ per cent S. S., 22½ per cent distilled water, 10 per cent sludge	1.68	1.2253	0.59	.7671
(d) 45 per cent S. S., 45 per cent distilled water, 10 per cent sludge	1.12	1.0492	0.39	.5911
(e) 22½ per cent S. S., 66½ per cent distilled water, 10 per cent sludge	0.60	.7782	0.16	.1903

If $\log C$ and $\log \frac{X}{M}$ (or $10\ C$ and $10 - \frac{X}{M}$ for convenience) be plotted the curve is almost a straight line. This signifies that the clarification action approximately follows the adsorption equation. This result was confirmed by repetition of the experiment on a number of occasions. Different amounts of sludge and different times of agitation were employed, but the adsorption equation was fairly closely applicable.

The classes of reactions already known to follow this equation are:

1. True adsorptions, e.g., by charcoal or other similar well-known adsorbents.
2. Catalytic actions.
3. Enzymic actions.

Knowing that the adsorption formula is applicable, one is enabled to understand why the reaction can efficiently take place even in such very dilute mixtures as ordinary sewage, for if the supply of adsorptive or catalytic surface (or the amount of enzyme) is adequate, the initial concentration of the sewage has little effect on the equilibrium concentration, i.e., the amount of impurity left. Further, adsorption, catalysis, and enzyme action are all surface actions, and as such depend on the initial state of the active surfaces. This being so, there is an obvious necessity for a reactivation stage during which stage the active surface is renewed.

The agreement with the adsorption formula, loss of activity during clarification and restoration of this power of clarification during re-aeration leads to the important inference that the real biological work is done during re-aeration when the enzymes (and perhaps other products) are produced, whilst the actual clarification stage represents little more than a physical or chemical reaction of the enzymes.

Experience on Percolating Beds.—It is highly desirable in studying the activated sludge process that the 30 years or so of research and experience on percolating beds should not be lost sight of, and an experiment of Scott-Moncrieff throws very great light on the theory of both percolating filters and of the activated sludge process. In 1898 he constructed a filter of superimposed trays of media, and found that if the sequence of the trays was altered the action of the filter was impeded. Not until the original conditions were again established could proper purification be obtained.

We know today that clarification takes place in the upper part of the percolating filter and that nitrification occurs below. The percolating bed, then, in a fairly efficient manner separates the clarification and nitrification stages.

When Scott-Moncrieff tried to reverse the order of the stages he was obviously trying to reverse an order which had naturally established itself, and we may be very sure that there must be some sound reasons for the national establishment of this particular order of stages. Study of these reasons cannot fail to be of great importance.

Stages of the Activated Sludge Process.—It seems almost impossible to avoid the inference that the activated sludge process should be separated into stages for the more efficient operation of each stage.

The stages which suggest themselves now are:

1. Clarification.
2. Reactivation of restoration of the powers of clarification.
3. Nitrification.
4. Reactivation of the special nitrifying sludge (if possible).

Although logical to split the process into stages, it must, of course, be recognized that economic considerations must prevail, and until we have learned to conduct each stage at its maximum speed and efficiency, it may be cheaper to carry on with a comparatively slow combined stage process.

Sewage Effluent Tasted Good, Anyway

The Ohio Health News of July 15 is responsible for the following:

"From an isolated school district in the northern part of the state, where the board of education, some time ago, installed sewage treatment works, comes an authenticated story of two fishermen who drank of the effluent and found it good. According to the clerk of the board of education, two men were fishing in the stream into which the effluent drains through a tile. They noticed some clear water flowing through the tile, and drank of it. Going up through the farm to the house, they commented to the farmer on the excellence of the water, and asked him if it came from a spring. It was about the best water they ever drank, they said, and they remarked 'how nice it would be' if they could have such water piped into their homes in the city.

"When they were told where it originated, the water did not seem quite so attractive to them for drinking purposes—but that is a matter of esthetics."

Forestry to Protect Reservoirs

The City Waterworks Department of Akron, O., has developed a transplant nursery in which more than 200,000 seedling trees are growing to a size that will enable them to compete with heavy sod, according to reports to the United States Forest Service. In Barberton, O., the City Waterworks Department began planting on a large scale this year, and plans, along with the reforesting of idle land, to develop a wide shelter belt of pine or spruce all around the large city reservoir. Such a shelter belt prevents much debris from being carried into the water, in addition to acting as a soil binder.

Qualifying Bidders on Public Works

Report of Committee of City Engineers Association of New York State

The prequalification of bidders on public works was recommended by a committee of the City Engineers Association of New York State in a report presented Sept. 27 at the fall meeting of the association. The committee consisted of Harry R. Hayes, chairman, Albany, N. Y.; M. W. Plumb, city engineer, Malone, N. Y.; and Leonard Bergman, city engineer, Jamestown, N. Y. The report and the proposed law follow in full:

Your committee feels that it is an essential duty of a public official to endeavor to eliminate some of the many difficulties which now attend the administration of public works. We appreciate that it is in the interest of the public that every effort should be made to guarantee the prosecution of public work with the greatest degree of efficiency. Losses, delays and inconvenience to the public have been seriously encountered on many public construction projects.

The cause, in many instances of unsatisfactory performance of public work, is due to the fact that the successful bidder is not competent to thoroughly undertake the contract, and lacks either the professional skill, organization, or financial ability to properly complete the project.

Such situations are the result of the present system of awarding contracts to any concern who can furnish a bond. The furnishing of a bond does not in any way guarantee the responsibility of a contractor. The bonding companies have repeatedly made such assertion. The bond is only an assurance that if the contractor fails that the bonding company will assume the obligation of the contract.

The courts have held in numerous instances that it is the plain duty of the contracting public body to investigate the qualifications of a bidder before making an award. This right has not been very generally exercised in this state. Possibly due to the different interpretations of the word "responsibility" as applying to public contracts and because the laws pertaining to the award of public contracts have not definitely expressed the authority which the courts have held that public officials do possess.

It is the opinion of your committee that the policy of qualifying bidders should be adopted in some form. There are two methods which may be adopted. Either to examine the qualifications of a bidder before proposals are received or to determine them after the receipt of bids. In either method the plan of investigation could follow that outlined in the "Standard Questionnaire" recommended by "The Joint Conference on Construction Practices." This conference included committees from: American Association of State Highway Officials, American Institute of Architects, American Institute of Consulting Engineers, American Society of Mechanical Engineers, American Society of Civil Engineers, American Society for Municipal Improvements, Associated General Contractors of America, Highway Industries Exhibitors Association, National Association of Casualty and Surety Agents, Surety Association of America.

Your committee feels that every public body should have some plan whereby the fitness of a bidder to assume a specific contract can be determined. To be most effective, however, the qualifying procedure should be carried out before the bidder is allowed to obtain plans and specifications.

This system avoids such unpleasantness as charges of favoritism when it becomes necessary to reject the bid of an unqualified contractor after the proposals have been received. It assures the contractor the award if his bid is low. It gives the public body the opportunity to establish a qualified list of contractors and to arrange them in classes according to the magnitude or size of the contracts upon which they can qualify.

Your committee, therefore, believes that the most satisfactory system of qualification is the one which requires it prior to the reception of bids and therefore, recommend the approval of the following law.

Proposed Law for Prequalification of Bidders

1. Every officer of the State government, or of any city who is charged with the duty of receiving bids for or awarding a contract for the construction of a public improvement shall, before furnishing plans or specifications or proposals therefor to any prospective bidder desiring to submit a proposal for the construction of such improvement, require that person to submit a full and complete statement, duly verified, of his financial ability, equipment, experience in the construction of public improvements, and of such other matters as the officer may require to assist him in determining the qualifications of that person to undertake and fully perform, in a satisfactory manner, the work contemplated. Such statement shall be filed with the written answers to questions propounded in a standard form of questionnaire to be furnished by the officer to all prospective bidders, and shall be filed with the officer not less than five days prior to the day upon which bids are to be opened.

2. Before the bids submitted for the construction of a public improvement are opened, the officer charged with the duty of awarding the contract for the construction thereof shall consider the statements so filed and determine to his satisfaction those prospective bidders who are duly qualified to undertake and fully perform in a satisfactory manner, the work required; and no contract for the construction of a public improvement shall be awarded to any person, who in the opinion of the officer, is not thoroughly qualified to undertake and fully perform the work in a satisfactory manner, or who has not filed the statement as provided herein.

3. The officer may, at any time after due consideration of the statement filed by any prospective bidder, notify such bidder that he is qualified or not qualified, as the case may be, to undertake and fully perform, in a satisfactory manner, the work contemplated, and it shall be the duty of the officer to make a public announcement, immediately before the bids are opened, of such persons to whom plans, specifications or proposals have been furnished who are deemed to be fully qualified to satisfactorily perform the work required.

4. When any one person shall be the low bidder on two or more contracts for the construction of public improvements neither of which has been awarded, and such person is not in the opinion of the officer, qualified to undertake and fully perform, in a satisfactory manner, the work contemplated under all of such contracts, the officer shall require that person to immediately withdraw one or more of his bids and shall award to that person only such contract or contracts as he shall deem qualified to undertake and perform.

5. No action or proceeding of any nature or description out of any court of competent jurisdiction shall lie against any officer of the state government, or of any city, because of his refusal to award to any person a contract for the construction of a public improvement for the satisfactory performance of which such person is not, in the opinion of the officer, fully qualified, or who has failed to comply with the provisions of this chapter.

6. The term "person" as used herein, means any individual, co-partnership, association, corporation, or joint stock company, their lessees, trustees or receivers.

The term "officer" as used herein, means any officer, board, commission, committee, department or other branch or bureau of the state government, or of any city.

7. This chapter shall apply only to contracts for public improvements, proposals for the construction of which are required to be advertised for by law.

The term "public improvement," as used herein, shall mean an improvement upon any real estate belonging to the state, or to any city.

8. This act shall take effect immediately.

Results of Experiments in Determination of Biochemical Oxygen Demand

Paper Presented March 23 before
New Jersey Sewage Works Association

By LEROY FORMAN
Senior Chemist, Bureau of Engineering, New Jersey State Department of Health

THE biochemical oxygen demand determination of crude sewage, sewage plant effluents, trade wastes, and polluted streams has become generally recognized as an important test for determining their strength, degree of purification, and character of pollution; and discussions of procedure for carrying out the determination are becoming more and more frequent. At the present time there seems to be a great need for standardizing a procedure whereby uniform and consistent results, that will check, can be obtained.

This was demonstrated to me most forcibly last fall when through necessity a number of bichemical oxygen demand determinations were made up in the field and carried around in a machine three days before they could be brought to the laboratory for completion. The results on raw samples were around 60 parts per million of biochemical oxygen demand, which seemed ridiculous and all out of proportion in view of the apparent strength of the sewage both by appearance and as indicated by the figures obtained in the various other chemical determinations. Soon thereafter, the following experimental work was undertaken, which I believe covers the various factors entering into the biochemical oxygen demand determination.

Temperature of Aeration of Diluting Water and Aging.—Portions of distilled and tap water were aerated at two temperatures, 50 deg. F. and 74 deg. F., and after a few minutes when all visible entrapped air had disappeared their dissolved oxygen content was determined. They were then allowed to stand at room temperature stoppered, and dissolved oxygen determined each day.

The water aerated at 50 deg. F. contained 11.8 parts per million of dissolved oxygen; whereas that aerated at 74 deg. F. contained 9.1 parts per million. After two days the former lost 3 parts of oxygen and the latter 0.8 parts. It required eight days standing at room temperature for the two waters to reach the same oxygen content.

A number of samples from time to time of freshly aerated water were allowed to age a week or more and the rate of loss of dissolved oxygen noted. From 0.4 to 0.7 parts per million were lost within a week with water that was not saturated when aerated. With a strong sewage, 2 per cent is mixed with 98 per cent of dilution water; it is very essential then to have a diluting water that has been sufficiently aged as the results obtained must be multiplied by 50 to obtain the biochemical oxygen demand. Freshly aerated distilled water even though not saturated when put in bottles and incubated at 20 deg. C. loses a certain amount of oxygen.

Temperature of Incubation. — One liter of a 2 per cent solution with each of ten samples of sewage from as many towns was made both with distilled water and Trenton tap water that had been aerated and aged at room temperature for two weeks. Three bottles of about 250 c. c. capacity were filled from each liter and one set was incubated for five days at 10 deg. C., another at 220 deg. C., and the third at 31 deg. C.

It was found that the average variation was 5.06 per cent in the ten samples for each degree centigrade between 10 deg. C. and 22 deg. C. incubating temperatures when distilled water was used for dilution, and 3.90 per cent when tap water was used. Between 22 deg. C. and 31 deg. C. incubating temperatures, the average variation for each degree was 0.91 per cent with distilled water and 0.93 per cent with tap water. It was noted that in nearly every instance dilutions made with tap water seem to give higher results than dilutions made with distilled water.

Results of Using Distilled and Trenton Tap Water For Dilution Purposes. —The two waters were aerated at room temperature (74 deg. F.) and allowed to age two weeks before use. The incubation temperature for the diluted sewages was 20 deg. C. In this series 23 samples of sewage from six towns were used consisting of 10 raw sewage samples, 10 Imhoff tank effluents, 1 sprinkling filter effluent, 1 secondary settling tank effluent, and 1 creek water, all run in duplicate.

The average biochemical oxygen demand for the entire 23 samples was 145 parts per million with distilled water and 180 parts per million with Trenton tap water, an increase of 35 parts per million with tap water. When divided into the different kinds of sewage the results are shown in Table I.

The per cent difference between the distilled and tap waters is about the same for the raw and tank effluents; namely, 24.4 per cent and 24.1 per cent respectively. The figures using the two kinds of water for the secondary treatment effluents are fairly close.

The greatest difference in parts per million of biochemical oxygen demand in the check determinations on the same sample was 30 with distilled water and 20 with tap water; the average with distilled water, 11.1 parts per million, and with tap water, 6.07 parts per million; while standardizing temperature of aeration of dilution water, aging and temperature of incubation shows considerable improvement in obtaining closer checks and more consistent results, tap water gives higher and still more consistent and closer checks. It was then thought that the difference between the pH value of the two waters might be the answer. The pH value of the distilled water used was 7.1 and the tap water 7.4. To check this theory 25 parts per million of acid sodium phosphate and 25 parts per million of basic sodium phosphate were added to two portions of distilled water, the former had a pH of 6.6 and the latter 7.6. Several samples of sewage were then diluted with the above two dilution waters as well as with plain distilled water and also the tap water.

It was found that the average difference of biochemical oxygen demand in the checks on four sewage samples was 45 parts per million with distilled dilution water with a pH of 6.6; 25 parts per million with plain distilled water pH 7.1; 7.5 parts per million with distilled water of 7.6 pH; and 5 parts per million with tap water. Although the average difference in the checks of the biochemical oxygen demand between the samples with distilled water of 7.6 pH and tap water was slight, the tap water gave an average biochemical oxygen demand of the four samples of 175 parts per million and the distilled water of 7.6 pH

Table I

Kind of Sewage	Distilled water	Tap water	Difference	Per cent distilled lower than tap
Average B. O. D. of 10 raw samples	172	214	42	24.4
Average B. O. D. of 10 tank effluent	145	180	35	24.1
B. O. D. of sprinkling filter effluent	72	78	6	8.3
B. O. D. of Secondary settling tank	80	84	4	5.0
B. O. D. creek water	10.4	12.5	2.5	24.0

was only 138 parts per million or a difference of 37 parts per million.

Finally another series was made up using all the information we already had in addition to making up several synthetic dilution waters containing sodium, potassium or calcium bicarbonate in quantities approximating the inorganic mineral content of the Trenton tap water. Seven samples of sewage were diluted in duplicate with each of the following five dilution waters:

(1) Distilled water containing 60 parts per million of Sodium bicarbonate pH 7.7.
(2) Distilled water containing 100 parts per million Calcium chloride pH 7.3.
(3) Distilled water containing 60 parts per million of Potassium bicarbonate pH 7.6.
(4) Distilled water with nothing added pH 7.1.
(5) Trenton tap water containing 75 parts per million. Inorganic salts pH 7.4.

The average difference of biochemical oxygen demand in the duplicate determinations with (1) was 4.3, (2) 8.0, (3) 4.3, (4) 5.0, and (5) 4.3 parts per million respectively.

The average biochemical oxygen demand of the seven sewages in duplicate was as follows:

(1) Distilled water and sodium bicarbonate	162
(2) Distilled water and calcium chloride	182
(3) Distilled water and potassium bicarbonate	186
(4) Distilled water plain	136
(5) Trenton tap water	192

From the above it will be seen that for the most consistent, uniform and also higher results the potash salt is superior to either sodium or calcium salts added to distilled water. It is also interesting to note the very much lower results obtained with plain distilled water than with distilled water to which any of the inorganic salts were added: 136 against 162 for sodium salts, 182 for calcium salts, 186 for potash salt, and 192 for Trenton tap water.

Conclusions.—No single factor alone that was tried in these experiments is responsible for obtaining maximum consistent results that will check, but a combination and close adherence to all factors, temperature of aeration, aging, temperature of incubation, mineralizing and pH are necessary.

Aged tap water of a good quality can be used satisfactorily for diluting purposes at any sewage plant, but when results are desired for the comparison of one effluent with another or many other effluents from various localities, it is advisable to use a uniform diluting water.

For a time it was thought that the nature of the material and the state of activity of the organisms associated with it was the principal factor in obtaining good results. This may still be a factor but is believed overcome or controlled by following the last series of tests.

The greatest factors for obtaining good results in biochemical oxygen demand determinations are: (a) mineralized water, preferably with potash salts, with a pH well on the alkaline side; (b) well aged diluting water; and (c) incubation at a uniform temperature and not below 20 deg. C.

Method Adopted by New Jersey.—In consequence of the above data the following method has been adopted as the tentative method for the determination of biochemical oxygen demand by the Bureau of Engineering, State Department of Health of New Jersey. This procedure gives a practical field method inasmuch as a supply of the aged synthetic dilution water is available in the laboratory.

Court Decisions Regarding Sewage Disposal

From Public Health Reports, July 5, 1929

Order of State Department of Health to City Relative to Sewage Disposal Upheld.—(Ohio Supreme Court; City of Bucyrus v. Department of Health of Ohio et al., 166 N. E. 370, 120 Ohio St. 426, 2 Ohio Bar 10; decided April 24, 1929.) The state department of health, acting under statutory authority and after complaint, investigation, notice, and hearing, ordered the city of Bucyrus to install works or means satisfactory to the state director of health for the collection and disposal of the sewage of the city in a manner to correct and prevent the pollution of the Sandusky River. In a proceeding in error from the department's order, the supreme court stated that all the questions raised were determined by its decision in the case of the State Board of Health v. City of Greenville, decided April 2, 1912, unless the adoption on September 3, 1912, of Article XVIII of the state constitution had so changed the relationship of municipalities to the state as to divest the state of its sovereignty over such municipalities in respect to sanitation within and in the vicinity of such municipalities. Said Article XVIII provided, in part:

> Municipalities shall have the authority to exercise all powers of local self-government and to adopt and enforce within their limits such local police, sanitary, and other similar regulations as are not in conflict with general laws.

The court's view was that the adoption of the article did not change the situation of the municipalities with respect to local sanitary regulations, except that before such adoption they had such power to adopt local sanitary regulations as had been conferred upon them by the legislature and since such adoption they had such power to adopt local sanitary regulations as had not been taken away from them by the legislature in the enactment of general laws. The court said:

> The effect of the constitutional provision granting to municipalities the power to adopt local sanitary regulations is, therefore, no different than though the power had been conferred by legislative enactment instead of constitutional provision; for, if conferred by legislative enactment, the act would be subject at all times to revision or repeal by the legislature. The constitutional provision conferring the power with the limitation that the municipal regulation must not be in conflict with general laws operates to bestow upon the legislature the same power to control sanitation by general laws that it had prior to the adoption of that article. The power conferred by that article is conditioned upon the legislature not having enacted general laws with which the local sanitary regulations of the municipality conflict.

The decision in the Greenville case was adhered to by the court.

With regard to the hearing before the health council, the court made the following observations:

> * * * While the technical rules of a hearing by a court are not required to be strictly observed in hearings before administrative bodies, it is the duty of such bodies to permit a full hearing before administrative bodies, it is the duty of such bodies to permit a full hearing upon all subjects pertinent to the issue, and to base their conclusion upon competent evidence; and such result can better be accomplished by a substantial adherence to the rules observed in hearings in court. In the instant case, the newspaper article was not competent evidence. * * * The reports of the engineers employed by the health department were official in character, authorized by statute, and were competent evidence in such hearing * * *. The city of Bucyrus was entitled to examine and to attempt to impeach such reports and each and every person who assisted in gathering data and compiling such reports. The city of Bucyrus was entitled to present its own witnesses to disprove any of the facts testified to by the witnesses of the complainants, or any of the facts shown in the reports, and was entitled to file such papers in the case as it deemed essential to the preservation of its rights and the preservation of its cause or defense, and was also entitled to make such defense without the filing of an answer. * * *

The department's order was affirmed.

Order of State Health Department Concerning Sewage Disposal Upheld.—(Ohio Supreme Court; State ex rel. Neal, Director of Health v. Williams, Mayor, et al., 166 N. E. 377, 120 Ohio St. 432, 2 Ohio Bar 10; decided April 24, 1929.) In a mandamus action to enforce the laws relating to the pollution of watercourses, the petition charged that the respondents were causing sewage of the city of Delphos to be discharged into certain streams, in violation of statutes, in such quantities and of such character as to pollute the streams, and that this conduct constituted a public nuisance by making the streams a menace to public health and welfare in the vicinity. The petition contained proper allegations necessary to show that, pursuant to complaints filed, an examination of the situation had been made by the state director of health; that a hearing, after due notice, had been held; that findings had been made and respondents notified thereof and directed to make other arrangements, within a specified time, for the proper disposal of sewage in a manner satisfactory to the state health authorities; and that the time fixed had elapsed and respondents had refused to comply with the order.

The respondents challenged the sufficiency of the petition and presented many other issues for the court's consideration, such as the unconstitutionality of the law under which the health department acted, misjoinder of parties, omission of parties, insufficiency of findings made by the health authorities, unreasonableness of the order, and also the claim that, under the home rule provisions of the constitution, the city could not be controlled by the state health department with respect to its disposal of the city's sewage.

The supreme court, which found against the city, said:

> This court is of the opinion that every issue presented by the pleadings and urged in the arguments and briefs of counsel has been fully and completely covered by the decisions of this court, and that there is now nothing further to be said on the subject.

Our New Title, "Water Works and Sewerage"

A year ago "Water Works" was merged with "Municipal and County Engineering" under the title "Municipal News and Water Works." For 12 years "Water Works" had specialized in the hydraulic field, and it has continued to devote nearly all its space to municipal hydraulics during the past year. This policy of hydraulic specialization is to be continued.

During the past year many of the old readers of "Municipal and County Engineering" have been induced to subscribe for "Roads and Streets," so that they now receive a semi-monthly municipal news service. Published about the first of the month, "Water Works and Sewerage" covers hydraulic and sanitary engineering features, while "Roads and Streets," which is published about the middle of the month, covers the pavement and street features of municipal engineering and contracting.

The third magazine of the Gillette Construction Group is "Engineering and Contracting" which was founded 24 years ago next January by Myron C. Clark and Halbert P. Gillette. This magazine covers bridges, buildings and heavy construction such as railways, irrigation canals, etc. The three magazines together give complete coverage of the civil engineering field and its allied contracting.

Municipal hydraulics, to which "Water Works and Sewerage" is devoted, embraces the allied fields of city water supply and sewage treatment and disposal. It costs about $80 per capita to build a modern water works system and almost an equal sum to build a sewerage system. Since nearly 75 per cent of our people live in incorporated towns and cities, we have about 90,000,000 urban residents. To reproduce their water works and sewers would cost not much less than $1,400,000,000; it would cost fully that if they were all adequately served. Most of the smaller towns have inadequate hydraulic plants and service. The same is true of many of the large cities. Inadequacy of plant is seen wherever water meters are not installed, which unfortunately is the case in all too many instances. The same is true where hard water is not softened, where impure water is not chlorinated and where raw sewage is discharged into streams from which other towns and cities take their water.

There is a vast deal yet to be done by American engineers, superintendents and contractors before our systems of municipal water supply and sewage disposal may be regarded as being satisfactory, either from an economic or from a sanitary point of view.

This magazine was the first American magazine to specialize completely in municipal hydraulics. It is the only magazine devoted solely to water works and sewers. Last June its first Water Works and Sewerage Catalog issue was published, and distributed at the time of the annual convention of the American Water Works Association. Our readers will receive an even larger and more complete book of hydraulic reference data next June.

Predicting Storms by Static

Nearly 180 years ago Benjamin Franklin flew the famous kite whose string brought to earth an electric current from a cloud. He believed that the friction of the air electrified the clouds, and to this day that theory, with a few additions, is generally accepted. It is now believed that the disruption of rain drops also generates electric charges, and that charges so generated may be even more potent than charges produced by friction.

The editor believes this theory to be wrong. Instead of electricity being generated by the clouds, the editor believes that electricity generates the clouds, for he regards all cyclonic air-whirls as electromagnets whose free electrons are rotated by the earth's magnetic fields. Since our storms are all cyclonic, it follows that storms should invariably show electric effects. That this is at least the usual case is indicated by the static that has been found to be caused by many storms.

A. H. Harper, of the research department of the American Telephone and Telegraph Co., recently announced that by aid of two loop aerials connected to radio sets, he has been able to locate the position and trace the track of many storms. For example, a storm center was located northwest of the Great Lakes, Sept. 7, 1928; and six days later it passed near Houlton, Maine, accompanied by lightning. We predict that this radio method of discovering storm centers and tracing their tracks is destined to revolutionize the prediction of storms.

In several articles the editor has given his electromagnetic theory of air-whirls, but it will be very briefly outlined again.

Air contains free electrons. Free electrons tend to rotate around the lines of force of a magnet. The earth is a compound magnet. So is the air above it. Free electrons moving in the same direction in approximately parallel orbits constitute an electromagnet. Hence air, if sufficiently charged with free electrons, is given a whirl. When thus whirling the air-whirl is itself an electromagnet. Since parallel electric currents in the same direction attract one another, the electrons tend to become concentrated in a belt around the whirl center. Hence air flows from the center as well as from the outside toward the whirl belt. Since opposite electric currents repel one another, the whirl-belt expands to a position of equilibrium. The net effect is low barometer near the center of the whirl-belt, but it is not this "law" that causes the air to ascend. Electromagnetic force pushes a cyclonic whirl-belt upward. The air is literally pumped upward by electromagnetic force. The rising air is cooled and tends to precipitate some of its moisture. Electrons act as centers upon which the moisture collects. Clouds form. When the

electromotive force becomes high, relative to the resistance, discharges occur. Moisture in the air is favorable to such discharges. So is great altitude, for as the pressure is reduced more electrons are set free.

Every statement in this last paragraph is founded upon electric theory established by experiment, yet, strangely enough, this theory of storms had not been suggested by any meteorologists and is still regarded with skepticism. Static electric theories had previously been suggested to explain ascending air currents, but they could not account for the magnitude of the barometric changes, and they made no attempt to explain the rotary nature of storms. On the other hand, the editor's electromagnetic theory accounts for every important feature of storms, such as: (1) Rotation, (2) ascent, (3) progression, (4) the subsequent "high" (anticyclonic), (5) electric charge, (6) inflow of the outer air, (7) low barometer at the center, (8) opposite rotation in the northern and southern hemispheres, (9) storm effects of sunspots (which are themselves electromagnets), and (10) the two stormy seasons that center around January and July when the axes of the earth and sun are in the same plane.

In addition to the ten features just named, there are many others that are explained by the electromagnetic theory, and without the aid of any other new theory. Also, although this theory is new, it rests upon facts established by laboratory experiments. None the less it will find "slow sledding," for old theories, however inadequate or incorrect, have the vitality of a cat with its nine lives raised to the ninth power.

The Need of a Large Research Staff in Our Weather Bureau

When our government follows the example of our great corporations and organizes a large research staff to investigate the causes of weather changes, we may hope for satisfactory progress in the art of weather forecasting. It will be replied by the Weather Bureau that much progress has been made, and that they are conducting researches; but the fact remains that although that bureau has been in existence nearly 60 years, it confesses inability to forecast weather much more than a week in advance.

A few years ago, Prof. Cleveland Abbe, then editor of the "Monthly Weather Review" (the government magazine) wrote the article on meteorology that was published in the Encyclopedia Britannica. Speaking of the influence of sunspots and other cosmical forces on weather, he said: "But, in the writer's judgment, these matters, while curious and interesting, have no appreciable bearing on the current important questions of atmospheric mechanics. . . . The leading meteorologists have relegated such questions to the care of theoretical astronomers and physicists until our knowledge is more firmly established." And he goes on to add that "it would be folly to spend time" on a study of cosmical causes of weather until a better knowledge is attained of the earthly causes which present such a "bewildering maze of problems." Thus, while admitting the existence of a "bewildering maze" he calls it folly to seek extrication from that maze by study of sunspot effects and the like!

That Prof. Abbe's spirit still is potent in our Weather Bureau was recently made clear to the writer when the editor of the Monthly Weather Review declined even to look at a manuscript that an hydraulic engineer offered to submit on the relation of sunspots to rainfall. That editor was so cocksure that no one could possibly discover any new and important relationship between sunspots and weather that he would not even spend a few minutes of his time reading the manuscript.

Not many months ago Prof. C. F. Marion, chief of the Weather Bureau, gave an interview to the newspapers in which he held up to ridicule all attempts at long distance weather forecasting. He was quoted as saying: "When long distance weather forecasting is on a scientific basis, rather than a foundation of mere guesswork, such forecasts will be made by the weather bureau." So, with "admirable scientific caution," he patiently waits, as his predecessors have waited for 58 years, for someone to show them how to make long distance forecasts. But his is like the adamantine mug of the man in the show window: "Make him smile and we will pay you $10." He dares anyone to change his expression of indifference or the belief that engenders it.

Meteorologists, according to Prof. Abbe, should wait for astronomers to pave a definite relationship between sunspots and weather. Well, Prof. Douglass (an astronomer) did that very thing nearly a generation ago, and so did Prof. Huntington (a geographer), and so did Prof. DeGeer (a geologist), but Prof. Marvin (the meteorologist) is still waiting. The clues that such scientists have furnished have not been diligently followed up by the Weather Bureau. It refuses to "smile," because it is resolved not to "smile." Small wonder that Father Ricard, the Jesuit astronomer and meteorologist, recently said that the heads of the Weather Bureau are suffering from "sleeping sickness."

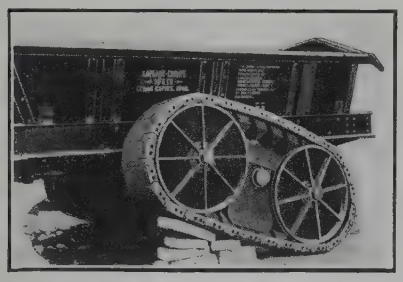
So far as farmers and hydraulic engineers are concerned—and we are now speaking in behalf of the latter—the Weather Bureau has failed to make any progress in solving the important problem of long-distance weather forecasting. We venture to say that in a year's time a committee of hydraulic engineers would make more progress in solving this problem than the Weather Bureau has made in the 58 years since it was founded.

We do not wish to be understood as condemning what the Weather Bureau has done, but what it has failed to do. Its "Monthly Weather Review" is a valuable magazine. If it had never done more than recently to translate and reprint Prof. Fritz's old (1893) article on "The Periods of Solar and Terrestrial Phenomena" (M. W. R., October, 1928), it would have justified all the money spent in publishing the magazine since its inception. The same is true of Homer W. Clough's recent article (M. W. R., July, 1928) on the 28-mo. solar and weather cycle. Mr. Clough, we believe, is one of the Weather Bureau staff. What we urge is the organization of a large staff of competent researchers whose sole function shall be to try to fathom all the mysteries of weather phenomena. Such a staff would welcome aid from every source, looking, as it would, with friendly eye upon any suggestion, however fanciful it might seem, and enlisting the aid of men in every branch of pure and applied science. The trained researcher is never skeptical. On the contrary, he knows that from the most fantastical hypotheses the greatest discoveries have so often sprung, that he bids every Columbus "God-speed."

H. P. Gillette

La Plant-Choate Track-Type Wagon

La Plant-Choate Manufacturing Co., Cedar Rapids, Ia., have placed on the market a wagon track that is a big step ahead in their line of equipment. These



La Plant-Choate Crawler Wagon

new tracks are manufactured under license from the Caterpillar Tractor Co., San Leandro, Calif., and Peoria, Ill. Write La Plant-Choate for catalogs or see their nearest dealer for literature and demonstration.

Witte Produces Newly Designed Engine Powered Diaphragm Pumps

For jobs where accumulations of muddy, trashy water must be pumped, two specially designed, heavy-duty, engine-powered diaphragm pumpers are now offered to the construction and engineering field by the Witte Engine Works, Kansas City, Mo.

Each of these pumpers is a complete portable unit, direct, single reduction, gear-drive engine, pump and transmission being compactly and rigidly mounted on a rugged, all-steel truck. Capacities, per hour are, it is claimed, for the one outfit (No. 10), up to 5,000 gallons per hour, and for the other (No. 12 outfit with two intakes for working in one or two excavations at the same time), up to 10,000 gallons. Pumps are self-priming, and can be furnished with flexible hose and foot valve to water connection.

All bearings on engines, pumps and transmissions have compression grease cup lubrication. The engine crank case is enclosed, thus protecting moving parts from all dirt and sand. Gears are steel alloy and machine cut. Pump valves are wing-guided poppet type and have replaceable rubber facings. Valve seats are carefully machined. Lever-arm bearings have replaceable bronze bushings.

Reliable, low-cost power is provided by the all-fuel Witte throttling governor type "H" engine, WICO magneto ignition, weather and water proof. For general power use, the engine is quickly detachable from the pump, and drive pulleys can be put on the extended crank shaft on both sides.

The pumps are now available through the regular trade channels, as also are the various sizes and types of internal combustion engines which the Witte Company has developed in its half-century of exclusive engine manufacturing. The line now embraces units of 2, 3, 4, 6, 8 and 12 hp., and a special heavy-duty type in 20 and 30 hp. sizes, including power deep well and pressure pumps and power saws.

High-Pressure Double-Deck Compound Turbine-Generator

Several unusual or new features will be incorporated in two steam turbine generators which are to be added to the generating facilities of the Pacific Gas & Electric Co., San Francisco. The two machines, each rated at 50,000 kilowatts, will be the first of the new "double-deck compound" type, and will be fueled with natural gas piped from a source 240 miles away.

It is claimed the station will be one of the most efficient in the world, the result both of employing 1,250-lb. boilers and using natural gas as fuel. Each main 1,200-lb. turbine unit, of General Electric manufacture, consists of a high-pressure element operating at 3,600 r.p.m. and a low-pressure element operating at 1,800 r.p.m. The turbines, rated at 50,000 kilowatts each, are to be suitable for a maximum output of 62,000 kilowatts. Provision is made so that the low-pressure turbine can be operated from the high-pressure boilers with the high-pressure turbine shut down.

A new type of construction will be used, in that the high-pressure turbine and generator will be mounted on top of the low-pressure generator, thereby saving the foundation and the floor space ordinarily required for the high-pressure turbine. The result is a very compact unit.

In addition to the main turbines, two General Electric auxiliary turbines are included for driving the boiler feed pumps. These pumps, used with high-pressure boilers, absorb considerable energy, and therefore these turbines are much larger than usual. They are of the two-unit type, composed of condensing and non-condensing elements. The condensing element is coupled to one end of the pump and takes steam from the present 300-lb. boilers; the non-condensing element is coupled to the other end of the pump and takes steam from the cross-over between the main turbines. This arrangement permits the two elements of the turbines to be operated at times independently and at other times together, so as to maintain at all loads the most economical heat balance on the installation as a whole.

Lincoln New Kathode Welding Electrode

Extensive research and experimentation by the Lincoln research laboratories has made possible the offering to the trade of the New Kathode welding electrode by The Lincoln Electric Company, Cleveland, O. The electrode is manufactured for the arc welding of mild steel and for cast iron repair work.

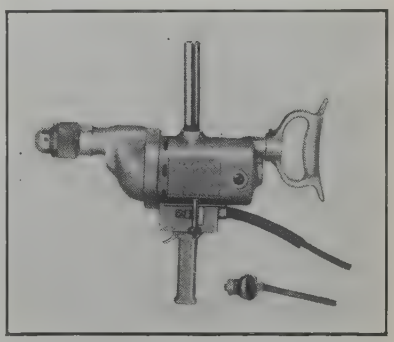
The composition of the New Kathode welding electrode, as well as the special treatment given in its manufacture, imparts qualities heretofore lacking in the usual electrode. Flowing easily with freedom from sputtering, the new electrode produces clean welds with minimum slag and oxidation. The high heat permissible for use with this fast running electrode makes possible increased welding speed. The quality of the weld is not sacrificed for speed of welding, as the New Kathode electrode fuses easily. The resulting weld on steel is soft and readily machinable.

The New Kathode electrode is manufactured in stock lengths of 14 and 24 inches. To provide best possible protection, during shipment, the rod is packed in metal containers holding 50 pounds each.

New "Wodack" All Purpose Drill

The new Wodack all purpose portable electric drill, made by the Wodack Electric Tool Corporation, 4627 West Huron street, Chicago, combines lightness with power and performs in an unlimited range of drilling requirements.

A General Electric motor of ample reserve power is built in for direct or alternating current of 60 cycles or less, 110-125 or 220-250 volts as desired. An oversize double pole, trigger switch in convenient position, insures long life. High grade ball and roller bear-

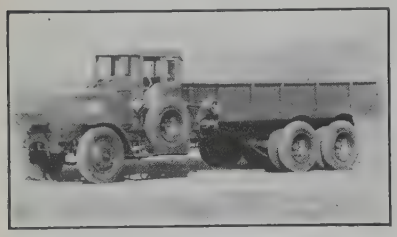


The New WODAK All Purpose Drill

ings are used, the heavy thrust loads being carried by Timken roller bearings. Hardened gears are simply assembled, grease compartments are designed for long periods of operation, and correct ventilation is provided for by an oversize fan for quick cooling during idle running.

New Mack Super-Duty Truck

Modern highway transportation requires speed either as a competitive element in the business of hauling or as the transportation element where it is one of the distribution or manufacturing processes in other industries.



Mack's New 6-Cylinder Super-Duty Truck

The road speed necessary to meet the demands for rapid delivery service has, heretofore, been obtained by reducing load capacities, using pneumatic tires and higher gear ratios with existing engines. This reduced the most essential element of hauling economy, which is capacity.

Mack now introduces the Super-Duty line of trucks, two models of which are designed to carry great loads at high speed.

The AP 4-wheeler and the AP 6-wheeler will carry from 7½ to 10 ton truck loads at 30 miles per hour and climb 20 per cent grades with ease provided the footing is given. They will haul 35 ton drawbar loads at 25 miles per hour. These massive AP trucks are powered by 6-cylinder high compression engines of 150 horsepower.

When 70,000 pounds or 35 tons can be hauled with one engine and one driver at a steady speed of 25 miles per hour, the tremendous possibilities in low cost transportation is evident.

Twenty-five miles per hour will generally equal the average speed of lighter vehicles so that the service element of speed is combined in the Mack Super-Duty line with the economy of great capacity.

In addition to the AP model, the Super-Duty line includes the famous AC model with a new high compression engine and six wheels. This Super-Duty vehicle is designed, not for speed, but for hauling heavier loads under the difficult conditions encountered in the earth moving industry and other fields where the greater traction and better load distribution of six wheelers is recognized.

The most outstanding innovation, in addition to the tremendous power in the model AP, is the six-wheel feature with rear, four-wheel drive. In this, Mack has retained its characteristic heavy duty feature—chain drive.

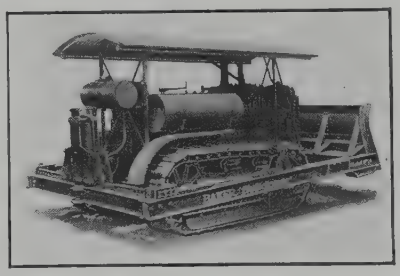
The rear truck consists of two dead axles mounted through rubber shock insulators to massive spring tips. The spring is anchored at its base to a horizontal torque bar mounted in the frame so that the load is equally distributed between the two rear axles. This distribution which is the most desirable from a standpoint of road impact, can be obtained on the Mack Super-Duty models because the tractive resistance of all four wheels is effective through four-wheel drive.

The drive is effected by means of four sets of driving chains, each set of rear wheels driven by an independent jackshaft. Brakes are on all rear wheels as well.

Baker Bulldozer Announced

The Baker Mfg. Company, Springfield, Ill., has just developed the Baker hydraulic bulldozers for 30 and 60 Caterpillar tractors.

The frame of the bulldozer surrounds the tractor, mounted and pivoted at the rear of the tractor draw bar and on outer ends of the rear axle of the tractor. The pull is thus at three points in a straight line with even distribution of power. Heavy and rigid construction of both moldboard and frame give the bulldozer exceptional strength.



Bulldozer Developed by Baker Mfg. Co.

The raising and lowering of the blade is accomplished by means of an oil-operated gear pump, directly connected to the power drive shaft of the tractor, which operates a hydraulic ram. Mounted forward of the center of the truck frame on each side is a heavy steel bracket clamped to the truck frame of the tractor. At the top of each bracket is a roller chain which operates over a cast steel sprocket mounted in suitable bearings on the side of the frame. As the roller chain is connected to the hydraulic ram at the rear, the vertical action of the ram lifts the moldboard off the ground to the required height.

A hand lever conveniently located near the tractor operator's seat controls the raising and lowering of the blade.

The particular advantages claimed for the Baker bulldozers are: (1) Ability to operate various distances below the level of the track of the tractor, (2) Higher elevation of the blade, (3) Keeping a more nearly level grade, (4) Strength and (5) Easier operation.

Hyatt Develops New Bearing

To satisfy an increasing demand for a roller bearing interchangeable with standard S. A. E. single row ball bearings, but having greater load capacity, the Hyatt Roller Bearing Company of Newark, N. J., are now manufacturing single row radial bearings.

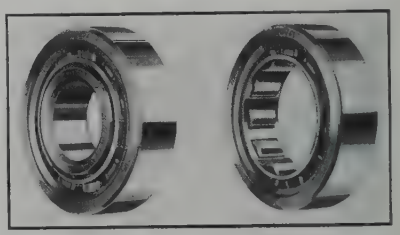
This new line of Hyatt single row radial bearings, made up of solid rollers, is not intended to replace the standard Hyatt roller bearing which uses spirally wound rollers, but is offered as a supplement to it, for positions in which space limitations exist, and loads beyond the capacity of ball bearings must be sustained.

The design employed is one in which the rollers are permanently retained with the outer race, the inner race being separable.

A separator, floating on the rollers, spaces them properly, and heat treated end rings retain them endwise within the outer race. The end rings and separator function to keep the rollers in proper alignment insuring positive contact along their full length. This full line contact of the rollers, the Hyatt Company states, enables their single row radial bearings to sustain greater loads than can safely be carried by ball bearings of equivalent sizes which have only spot or point contact between balls and races.

The manufacturer states that the rollers and races of this bearing are made of a special analysis chrome nickel alloy steel, and the end rings are of vanadium steel to eliminate any wear by the ends of the rollers. The roller separator is so made that the pockets are absolutely parallel and equally spaced, thus assuring uniform load distribution on the rollers.

It is further stated that the possible separation of this bearing into two parts, the inner race being removable, offers opportunities of developing more economical methods of assembling for all applications with or without the inner race. The roller ends are sufficiently rounded to facilitate assembly where the inner race is not used and both the outer and inner races are chamfered at one end.



The Hyatt Single Row Radial Bearing With the Inner Race and With the Inner Race Removed to Show Roller Construction

Hyatt single row radial bearings are now in regular production in a range of sizes sufficient to cover the needs of the present for this type of bearing.

DISTRIBUTOR NEWS

Clark Operates Model Foundry
Interior View of the Iron Foundry Operated by H. W. Clark, Mattoon, Ill., Manufacturers of Clark Water Works Necessities. This Is One of the Most Complete and Up-to-Date Gray Iron Foundries in the Middle West. The Building Is of Special Design to Accommodate the Travelling Crane Equipment, and Laid Out for Economical and Efficient Production. Nothing Is Done by Hand That Can Be Done by Automatic Machines from the Preparation of the Sand to the Ramming or "Squeezing" of Patterns in the Flask. The Cupola Capacity Is Twenty-four Tons a Day.

General Electric Holds Board Meeting on Electric Yacht

A recent meeting of the board of directors of the General Electric Company was held abroad the "Viking," a new 263-foot electric yacht owned by George F. Baker, Jr. The yacht was boarded at 26th Street and East River and cruised along Long Island Sound.

At the meeting announcement was made of the retirement of Allen H. Jackson, who has been general counsel and vice-president of the company since 1922. Mr. Darius E. Peck was elected to fill the position left vacant by Mr. Jackson's resignation, and the president of the company, Mr. Gerard Swope, stated the company would still be able to call upon Mr. Jackson in matters requiring consultation.

Mr. Peck, the newly elected vice-president, is a graduate of Yale University, and practiced law in New York City from 1902 until 1921, when he became a member of the law department of General Electric Company and moved to Schenectady.

The retiring vice-president, Mr. Jackson, joined the General Electric Company in 1902, as one of its attorneys. In 1922, the year in which Gerard Swope succeeded E. W. Rice, Jr., as president of the company and Owen D. Young succeeded the late Charles A. Coffin as chairman of the board, Mr. Jackson was appointed vice-president and general counsel.

The yacht on which the directors met, was electrified by the General Electric Company and exemplifies the first pleasure craft to be equipped with turbine electric propulsion, according to statement of one of the company's officials. The yacht was designed by Theodore D. Wells and built by the New Port News Shipbuilding and Drydock Company. It is of twin-screw type, each propeller being driven by a 1,300 shaft-horsepower motor from electric power supplied by two turbine generators. All auxiliaries are electrically operated.

The Wagner Electric Corporation of St. Louis, Mo., has moved its Cleveland service station and branch sales office to a new building at 3756 Carnegie Ave. The Cleveland office handles the entire Wagner line of motors, transformers, fans and Lockheed Hydraulic brakes, not only as a branch sales office, but also as a repair shop and service station.

North Western Buys Graver Softeners

The Chicago and North Western Railway Co. has contracted with Graver Corp., East Chicago, Ind., for three complete Graver Water Softening plants. The sizes and locations of these plants are: Clyman Jct., Wis., 20,000 gal. per hour, with additional storage for 60,000 gal. South Janesville, Wis., 15,000 gal. per hour, with additional storage for 35,000 gal. Jefferson Jct., Wis., 12,500 gal. per hour, with additional storage for 50,000 gal.

All of these plants will be equipped with the new Graver chemical control equipment, brought out within the past year. The Graver control mechanism consists primarily of a standard commercial water meter installed in the inlet line to the softener. This meter is attached to the feed pipe in the chemical tank and allows the chemicals to flow into the softener in direct proportion to the water.

The North Western has also contracted with Graver Corporation for an additional tank 21 ft. dia. x 52 ft. high to enlarge the capacity of the Graver Softener installed at Boone, Ia., several years ago.

Continental Motors an Exhibitor at Aeronautics Exposition

C. P. Russell, aeronautical sales manager for the Continental Motors Corporation of Muskegon, Mich., together with F. T. Gould, was in charge of Model A70 160 hp. radial engine and component parts at the Aeronautical Exposition held in Cleveland recently in conjunction with the National Air Races.

At the time this item went to press it was announced that the Continental powered plane would make a number of trips between Cleveland and Detroit during the races to transport members of the aeronautical division to Cleveland.

Bendix Aviation Takes on New Subsidiary

The East Orange plant of the Eclipse Machine Company has been taken over as a subsidiary unit of the Bendix Aviation Corporation and is to be known as the Eclipse Aviation Corporation.

This plant will continue to produce a complete line of starters for aircraft, as well as other aircraft equipment and aeronautical devices now being developed.

Schwanhausser Goes to Buffalo as Manager for Worthington

Mr. E. J. Schwanhausser, who entered the employ of the Worthington Pump and Machinery Corporation while a student at Stevens Institute of Technology, has just been appointed manager of that company's Buffalo works. Mr. Schwanhausser is but 35 years of age, and is one of the youngest executives in the Worthington organization.

E. J. Schwanhausser, Recently Made Manager Buffalo Works for Worthington Pump and Machinery Corporation

During the summers of 1912, 1913 and 1914, while still in school, he was employed in the various shops and on the testing floors at Harrison, and immediately upon his graduation in 1915, he was made test and erection engineer. He served successively in the condenser engineering department, as machine shop equipment engineer, superintendent of the machine shops, superintendent of field erection department and assistant to the manager.

In 1927 Mr. Schwanhausser was appointed assistant works manager, and it was while holding this position that he was made manager of the Buffalo works.

General Electric Distributing Companies Consolidate

Effective Oct. 1, 1929, the fourteen wholesale distributing corporations owned by the General Electric Company will be consolidated into the General Electric Supply Corporation (of Delaware), according to recent announcement. These companies have for many years distributed General Electric products and the plan, it is said, involves no change of ownership. The consolidated corporation will be in a much better position to offer nation-wide service through its ability to give service from any one of seventy-six houses, through interchangeability of stocks, and speedier and more economical operation.

The tentative organization plans indicate corporate officers and directors as follows:

Gerard Swope, chairman of board; C. E. Patterson, president and director; J. L. Buchanan, executive vice-president and director; J. G. Johannesen, vice-president, eastern region, and director; D. E. Harris, vice-president, western region, and director; N. R. Birge, A. D. Cameron, H. C. Houck, J. E. Kewley, G. C. Osborn, T. K. Quinn, E. O. Shreve, C. E. Wilson, directors; L. R. Link, secretary-treasurer; L. M. Nichols, comptroller.

Gardner-Denver Representatives Sent Far Afield

Two foreign branch managers of the Gardner-Denver Co. left the United States this week to take charge of their respective offices.

Ralph Scott, formerly sales manager of the drill division of the company, is enroute to London where he is to be stationed permanently. W. G. Agnew, who was until recently the Gardner-Denver sales representative in Arizona, leaves for Lima, Peru, to take charge of the office there.

The Gardner-Denver Co. manufactures rock drills, air compressors, slush pumps, drill sharpeners, high pressure drill steel forges and kindred machinery. Its main plants are located in Denver, Colo., Quincy, Ill., and La Grange, Mo.

Harold Smith Becomes Vice-President of Westinghouse

At a recent meeting of the board of directors of the Westinghouse Electric and Manufacturing Company, Mr. Harold Smith, general solicitor of the company, was elected vice-president.

Mr. Smith entered the legal department of Westinghouse in 1919, becoming general solicitor in 1926. Prior to that time he was engaged in the practice of law in Chicago, where he was a member of the firm of Glennon, Cary and Walker. He is a member of the state bars of New York and Illinois, and holds law degrees from Northwestern and Yale Universities.

His office will be in the Westinghouse Building, 150 Broadway, New York.

W. A. Gluesing Will Handle General Electric Booth at Petroleum Exposition

Arc welding and atomic hydrogen welding sets will be shown in operation, as well as motors and control for drilling, pumping and refining together with an educational exhibit from the General Electric laboratories will be on display at the International Petroleum Exposition to be held in Tulsa, Okla., early in October.

"Casey Jones," the toy train which obeys commands transmitted to it through the medium of an ordinary telephone transmitter, will be included in the exhibit which is under the direction of Mr. W. A. Gluesing for the General Electric Company of Schenectady, N. Y.

Riddell Company to Hold Pow Wow

A very enticing looking invitation has been sent out by W. A. Riddell Company for a three-day conference to be held in Bucyrus, Ohio. It is expected that there will be a large attendance made up of the sales organizations throughout the country representing Riddell. The meeting will be held at the Elks Club, Sept. 16, 17 and 18.

In addition to inspecting and watching demonstrations of the new machines and improvements which are to be announced to the trade at the Road Show in Atlantic City in January, it appears from the invitation that golf courses, fishing grounds, baseball fields, and even the lowly horse shoe will come in for due consideration.

The next issue will tell about results accomplished.

Appointed Sales Manager

W. H. Arnold has recently been appointed general sales manager for the Pittsburgh Valve, Foundry & Construction Company, making the fourth man to hold that position since 1900, when the constituent companies of Pittsburgh Valve were incorporated.

Mr. Arnold has been connected with the Pittsburgh company since 1905, and during his first twelve years acquired a thorough and comprehensive knowledge of the valve and piping business through working in the various departments of the plant.

Since 1917 he has been engaged in sales activity, bringing to the merchandising field all his knowledge of the products gained when identified with their manufacture. He is almost universally known not only among the power, industrial and oil interests of the East, but equally as well among the gas and oil interests of the mid-continent.

Thomas W. Hall Joins Fairbanks-Morse Co.

Announcement has been made to the effect that Mr. Thomas W. Hall, an engineer with a broad background of industrial experience and editorial work, has joined the staff of the Fairbanks-Morse organization. Mr. Hall will handle the type of work formerly under the direction of Mr. R. H. Bacon.

Mr. Bacon has been made manager of advertising for the company, and the nature of his new position will make it necessary for him to give up the editorial contacts which he has maintained for so many years with technical publications.

C. & O. Buys Large Softening Tank

The Chesapeake & Ohio Railroad has contracted with **Graver Corporation**, East Chicago, Ind., for a settling tank for a softening plant to be built at Boston, Ind. This tank is 40 ft. in diameter by 43 ft. high and has a downtake 12 ft. in diameter.

SERVICE EXCHANGE
For
Manufacturers or Distributors

Editor's Note.—From time to time we receive letters from distributors wishing to be put in touch with manufacturers of certain lines of equipment, or from manufacturers seeking representatives for their products. Items of this kind will be published and names and addresses furnished interested persons upon request.

New Lines Wanted

Equipment distributor in Pacific Northwest desires line of road building equipment, structural building equipment, dump bodies and truck hoists.

Distributors of contractors' and builders' machinery and equipment are seeking line of road forms, road finishers, batcher plants, clamshell buckets and drag line buckets, for Northern California territory. Now stocking equipment for several well known machinery manufacturers.

Manufacturers' agents representing well-known lines of water works equipment desire to secure line of pipe pushers and other similar equipment for California and Western Nevada territory.

Road machinery distributor would like to secure exclusive sales rights for state of Mississippi for line of automatic or self-loading wheeled scraper.

A Michigan distributor, with many years' experience, representing at this time prominent manufacturers of pumping machinery, offers the services of an established representative to manufacturers needing increased facilities in this region.

Manufacturers' representatives located in New York would like to add line of heavy contractors' equipment of established reputation, other than the lines now handled by them. They would like exclusive sales rights for such equipment.

Canadian distributor of equipment for water softening, filtration, sewage purification and pumping is interested in securing exclusive sales rights for kindred equipment in the Dominion.

Equipment distributor located in Michigan desires to add two or three good lines to serve territory in southeastern part of state.

Distributor of building specialties covering a territory of 100 mile radius from Chicago is equipped to represent additional lines.

District respresentative for sanitary engineering specialties would be interested in any line in the water works field. Has had experience in field of filters, softeners and water meters.

Civil engineer located in Porto Rico would like to hear from manufacturers desiring sole representation for their products in Porto Rico, Santo Domingo and Venezuela. Machinery for highway construction, purification plants, steel for buildings or bridges or other building materials and contractors' equipment.

Sales representative desires business connection with manufacturer of snow plows and road machinery for Minnesota and Northwest territory.

Machinery distributor established in Porto Rico and Santo Domingo would be pleased to make arrangements to take on new lines in these territories.

A contractor's superintendent, located in Florida, would like to represent some road equipment manufacturers in his territory.

Machinery company in the east is interested in representing established lines of road machinery, with the exception of graders.

Representatives Wanted

Manufacturer of truck, adapted to many uses, has attractive territory open in Missouri, Kentucky, Kansas, Nebraska and several southern states.

Manufacturer of hoisting machinery and air compressors has open territory in New York and New England states for aggressive distributor.

Manufacturer of excavating equipment desires to build up distribution organization throughout the country.

Manufacturer of non-clogging sewage pumps, both horizontal and vertical, as well as water works pumps suitable for municipalities of 50,000 or 60,000 people, is interested in securing additional sales representation.

Manufacturer of two cycle oil and gas engines in sizes from 30 to 125 H. P. adaptable for water works and many industrial purposes, wishes to establish points of distribution throughout the country.

Manufacturer of water works brass goods, would like to make proposition to manufacturers' representatives calling on waterworks trade.

New York corporation wishes to establish agencies throughout the country, prefer men specializing in heating and ventilating equipment.

A manufacturer of paving expansion joints is looking for distributors for northern California territory.

New York corporation, producing complete line of coal-tar products, wishes to make dealer connections throughout the country.

Manufacturer has some attractive territory available for distributors for complete line of generators, and centrifugal, diaphragm and piston pumps.

Manufacturer of metal lath, corner beads, channels and reinforcing mesh desires to secure distributors for products in the Southwest and Middlewest.

Manufacturer of building specialties wishes to establish distributors throughout the country. Manufactures concrete reinforcements and metal lath; Reed clips, form spacers, continuous column tie, continuous chair stirrup, beam bar spacers, slab bar spacers, continuous Hi-chair, continuous anchor slot, sleeping spacing anchor, humpback hairpin clip, lath hanger, stone anchors, straight wire lengths and special wire lengths.

Manufacturer of threadless pipe couplings and tees, with rapidly growing business, is seeking additional representatives.

Manufacturer of metal tie and spacer wishes to establish distributing points throughout the country.

Manufacturer of mechanical spreaders for cover material desires representation by organizations covering entire states. Several desirable states are still open. Number of inquiries now on hand for spreaders require immediate follow up.

Manufacturer of automatic dipper trip, adapted to any type shovel (steam, gasoline, diesel, electric, etc.); with rapidly growing business, is seeking additional representatives.

Manufacturer of complete line of Construction Equipment, mixers, saw rigs, plaster and mortar mixers and pumps, has an open territory in the state of Maine and is looking for an aggressive distributor to represent him there.

Manufacturer of rotary pump, especially designed for road construction work, has proposition for reliable distribution houses.

European Engineers Will Witness Lincoln Automatic Welding Demonstration

Mr. J. F. Lincoln, president of The Lincoln Electric Company, recently sailed on the Leviathan for London, England, where he will take charge of a demonstration for European engineers of the Electronic Tornado process of carbon arc welding which, since its inception, has revolutionized the method of automatic welding in this country.

The demonstration will take place at The Allen Liversidge plant. It is stated the demonstration has been arranged in answer to numerous requests from enginers and manufacturers in all parts of Europe.

Diesel Engine Manufacturers Organize Association

With the rapid growth in the use of Diesel engines in all types of industrial, public utility and municipal service, as well as in the railway, automotive and marine fields, the manufacturers of Diesel engines have realized the need for a closer contact with each other and with the problems of the user. As a result, twelve of the leading builders, representing practically the entire output of Diesel engines in the United States, have organized the Diesel Engine Manufacturers' Association. The association has as its primary object, the advancement of Diesel power in America and a broad program of cooperation with the users of this type of power.

Possibly the greatest benefit to the users of Diesel power will come through the development of suitable standards of manufacturing and engineering practice. Such active problems as specifications for oil fuels, wider distribution of accepted fuels and similar subjects will have the attention of the manufacturers.

It is also the intention to promote and extend the use of Diesel power. In accomplishing this object, more information will be made available on the application of Diesel engines in all types of service. In this connection the association anticipates the helpful cooperation of the technical, trade and business press of the country in presenting the story of what Diesel power is accomplishing all through the broad range of industry.

During the past few years there has been much definite progress in Diesel engine design. The manufacturers feel that the next most important step is to take greater advantage of the economies of Diesel engines in all types of application work. In the struggle to reduce production costs in all lines of manufacturing, power cost plays such an important part that the Diesel engine is effecting marked savings. In the field of power distribution, represented by the public utility organizations, there is now a definite trend towards the use of Diesel power. In this field it is expected that the Diesel engine will play an increasingly important part as the years go by.

In marine service more than half of the tonnage now being built is equipped with Diesel engines and in the work boat field practically no other type of power is being used. The first airplanes equipped with Diesel engines have recently completed very satisfactory test flights and a number of automobile buses and trucks are being driven with this form of power.

Although Dr. Rudolph Diesel, a German engineer, is commonly given credit for the invention of the engine which bears his name, the first commercial installation was in the United States in 1893. Not much progress was made from that time until about 1912 when a number of improvements again focused attention on this type of power. The progress since that time has been rapid until today more than 4,500,000 horsepower of these engines are in marine and stationary service. Of this total, some 3,000,000 horsepower is in the United States.

In addition to its low operating cost the Diesel engine has the interesting characteristic of being just as efficient in small sizes as in large units. The largest engine to date is 15,000 hp. and is installed in a German power station. Units of 5,000 to 8,000 horsepower are becoming quite common in the marine field. It makes little difference, however, whether the engine is 50 or 10,000 horsepower, it has the same high efficiency.

Because of the simplicity of the Diesel engine with its elimination of any kind of ignition system or carburetors, it has established some remarkable reliability records. Any number of instances have been recorded where Diesel engines have operated continuously for more than a year without a single shut down. Practically all of the first Diesel engines installed in the United States, some twenty-five years ago, are still in operation.

In addition to encouraging the wider use of this efficient prime mover the manufacturers are also giving more attention to better Diesel power plant design. Although the Diesel engine is a very simple type of prime mover its satisfactory operation depends on good plant layout. Cooling water and lubrication are especially important in this field and the layout of cooling water systems has come in for considerable study. The use of lubricating oil purifiers of various types and the development of completely automatic lubrication systems have eliminated difficulties in this phase of plant operation.

With all of this increasing interest in Diesel engines, the manufacturers through their Diesel Engine Manufacturers' Association, are filling an important need in making all sorts of information available to the public with respect to Diesel engines and their operation.

The following manufacturers are members of the association:

New London Ship & Engine Works, Electric Boat Co., Worthington Pump & Machinery Corp., Fulton Iron Works Co., Ingersoll-Rand Co., Fairbanks, Morse & Co., Nordberg Manufacturing Co., I. P. Morris & DeLaVergne, Inc., Winton Engine Co., Cooper-Bessemer Corp., McIntosh & Seymour Corp., Busch-Sulzer Bros. Diesel Engine Co., Hooven, Owens, Rentschler Co.

The president of the association is Henry R. Sutphen, president, Electric Boat Co.; E. T. Fishwick, vice-president of the Worthington Pump & Machinery Corp., is vice-president of the association; and Harlan A. Pratt, manager oil and gas engine department of Ingersoll-Rand Co., is secretary and treasurer. The association also employes M. J. Reed as research engineer, with headquarters at the association office, 30 Church St., New York City.

Bay City Shovels Expects New Offices to Be Ready for Occupancy in October

Bay City Shovels, Inc., of Bay City, Michigan, is looking forward to occupying early in October the new office building which is now in the course of construction under the direction of the Henry C. Weber Construction Company. The new building is being located on the Shovel Company property adjoining the factory and is of modern fireproof construction, reinforced concrete foundations and floors with hollow clay tile and face brick walls. The top floor will be occupied by the drafting room and engineering department, as well as an auditorium, and each floor will be provided with a fireproof storage vault.

The construction of the new office building is following out a previously announced expansion program, the first step of which is now completed in the new fireproof factory building equipped with an electric overhead traveling crane and containing 18,000 sq. ft. of floor space available for the assembly department. Mr. Morgan Ramsay, one of the officials of the company, states that the increased facilities were made necessary to meet the demand for the Bay City power shovels, and the machine shop division is now operating in day and night shifts.

Chicago Pump Company announces that Sprekelmeyer-McDonald Company, 709 Pennsylvania Avenue, Ft. Worth, Tex., has been placed in charge of that territory.

I. F. Baker to Direct Foreign Sales for Westinghouse

Mr. I. F. Baker, who has served the interests of the Westinghouse Electric and Manufacturing Company in many capacities since his apprentice days in 1909, has recently been appointed European sales manager of the Westinghouse Electric International Company and will be located at No. 2 Norfolk Street, Strand, London.

In 1913 Mr. Baker was transferred from the industrial sales department to the Westinghouse Export Company at East Pittsburgh, and in 1918 was transferred to the New York office of Westinghouse International, only to be sent the following year to Japan. While in Japan he became prominent in commercial and engineering affairs, serving as president of the American Merchants' Association of Tokyo and acting president of the American Association of Tokyo.

Just previous to Mr. Baker's appointment to the post in England, he had been power division sales manager of the Westinghouse Electric International Company, with offices in New York. It is said that Mr. Baker's efforts while in Japan contributed largely to the installation of one and a quarter million kv-a. of rotating apparatus, and two and a quarter million kv-a. of transformer equipment.

Universal Power Shovel Factory Moved to Milwaukee

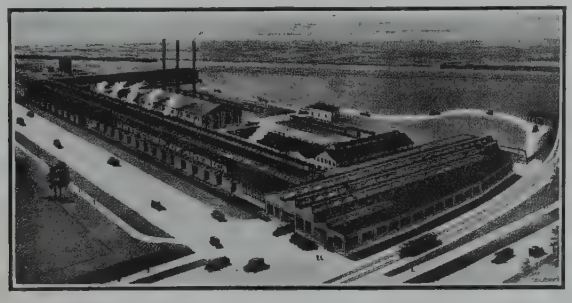
Announcement has recently been made of the removal of the factory and personnel of the Universal Power Shovel Company from Detroit to Milwaukee.

This company, which has been manufacturing excavating and material handling equipment for several years, was acquired a few months ago by the Unit Corporation of America, and since that time increased sales have made necessary better production facilities.

The new factory, located at Milwaukee, Wis., has just been completed. It is expected that the ample floor space and new, modern machinery will adequately meet the requirements of the company. Straight line assembly operations have been installed, and scientific production methods have been applied to the manufacture of the new line of gasoline power shovels, cranes, clamshells, draglines and backfillers.

Orders for machines and service parts are assured prompt handling because of the convenience of the plant's location for incoming and outgoing freight.

Headquarters in the new Bankers' Building, Milwaukee, have been established for the executive offices. The Universal Power Shovel Co. will continue to be represented in Detroit, Mich., with a branch office located at 462 Book Building.



Universal Power Shovel Co.'s New Factory at Milwaukee, Wis.

General Electric Pays Supplementary Bonus

The General Electric Company on Aug. 6 paid $1,825,832 in supplementary compensation to its factory and office employees who have been in the service of the company for five years or longer. This is the largest bonus ever paid by the company and represents five per cent of the earnings of employes for the six months ending June 30. Approximately one third of the total, or $584,342, was paid to employees at the Schenectady works.

During the past five and one-half years the company has paid a total of $15,757,722 in supplementary compensation to its employees under this bonus plan.

Announcement

The board of directors of International Combustion Tar & Chemical Corporation announces the election of George E. Learned as chairman of the board, succeeding F. J. Lewis; Dr. Walter Runge as president, succeeding W. H. Lewis; and Grant Thorn as vice-president in charge of sales.

It is stated that the resignations of Messrs. F. J. and W. H. Lewis were due to pressure of other business activities. Mr. J. F. Lewis will continue to serve as director of the International Combustion Engineering Corporation, of which the Tar and Chemical company is a subsidiary, and Mr. W. H. Lewis will be associated with it in an advisory capacity.

H. C. Collins to Represent Link-Belt in West

The crane and shovel division of Link-Belt Company, Chicago, announces the appointment of Mr. Harry C. Collins as its official representative in southern California, with offices in Los Angeles.

He will handle the Link-Belt line of shovels, cranes and draglines, devoting his entire time to but two lines—the other one being Plymouth locomotives, made by the Fate-Root-Heath Co., Plymouth, O.

H. C. Collins

For the past several years Mr. Collins has been president of the Collins-Kay Machinery Company, a position that he resigned from July 1 so that he might serve Link-Belt and Plymouth exclusively.

Mr. Collins is reported to be well and favorably known throughout southern California, this being the district he has served for the past 25 years, for seven years of which he was connected with Allis-Chalmers in the capacity of sales engineer.

During the remaining 18 years he has been in business in Los Angeles as a manufacturers' agent, handling general engineering work and heavy construction equipment for dams; municipalities; counties; sand, gravel and rock plants, and for contractors.

The Galion Iron Works & Manufacturing Company, Galion, O., announces the election of Mr. John L. Connors to the board of directors. Mr. Connors has also been made assistant general manager of this company.

R. W. Proctor Joins Cleveland Office of Van Dorn Co.

An announcement of interest to jobbers in the shop equipment field is to the effect that Mr. R. W. Procter, known to his friends as "Doc," has left the Black and Decker organization to become general sales manager of the Van Dorn Electric Tool Company. Mr. Procter has moved to Cleveland, where he will devote all his time and energy to promoting sales of the Van Dorn products.

The joy with which Mr. Procter is being greeted in his new undertaking is expressed by Mr. F. H. Zulauf, vice-president of the Van Dorn Electric Tool Company, in the following words:

"I believe that practically all of our jobbers who know him will agree that no man in our industry ever lost more hair in his sincere desire to help jobber distribution than R. W. 'Doc' Procter of the Black & Decker Manufacturing Company. If there is a manufacturer's man more loyal to the jobbers' cause, or one who has done more to help promote jobber distribution in the shop equipment field, I don't happen to know him. It is unnecessary for me to dwell on the qualifications of Mr. Procter as a merchandiser and sales executive, as his ability in this direction is well known and respected throughout the jobbing fraternity."

Westinghouse Acquires Newark Site for Service Shop

The Westinghouse Electric and Manufacturing Company recently purchased in Newark, N. J., a 22-acre site for a new warehouse and service station. It is planned that this new shop will serve the entire northern New Jersey industrial area.

Located at Haynes Ave. and State Highway, in the Port Newark Development, the site is conveniently located. The city of Newark contemplates building a belt line, connecting all of the railroad trunk lines, and is engaged in an elaborate program of highway improvements and grade crossing removal for this district.

General Electric Announces Change in Employees Insurance Plan

The General Electric Company has announced a revision in their group insurance plan so that premiums paid by new employees will be in accordance with their age, rather than an average rate common to all. President Gerard Swope also announced a modification of the plans for free insurance and additional pensions, also equalizing benefits according to age.

Heretofore, under the free insurance plan, the company furnished the same benefits to all employees, regardless of age. Under the revision the amount of free insurance given the company to new employees will vary according to the age of the person at the time he enters the service.

It is stated that the General Electric Company has more than 80,000 employees at the present time, and has in force a group life insurance policy amounting to more than $160,000,000. There are now approximately 1,000 former employees receiving pensions of disability relief and the pension trust has been built up to almost $9,000,000.

R. B. Marshall Joins Chain Belt Co.

Robert B. Marshall, well known conveyor sales engineer, has joined the Chain Belt Company's Conveyor Division with headquarters at the company's New York City office at 50 Church St. Mr. Marshall has spent the past 21 years in the conveyor business. In addition to the complete line of Rex Conveyors, he will handle the belt conveyors, glass batch handling equipment and silo storage system manufactured by the Stearns Conveyor Company of Cleveland a division of the Chain Belt Co. W. H. Quinn is the New York district manager for the company.

General Electric Exhibit at Aeronautical Exposition

The General Electric Company, according to announcement, a varied and interesting exhibit at the National Air Races and Aeronautical Exposition held in Cleveland Aug. 24 to Sept. 2.

Included in the exhibit were airport beacon lights, floodlights, magneto compass, magnetic compass and airplane engine supercharger.

Representatives of the G. E. Company include H. C. Ritchie, A. H. French and R. Stearns.

Wagner Electric Corporation of St. Louis announces that their Mr. Ralph R. Rugheimer is now a member of the Atlanta branch sales office. Mr. Rugheimer has spent quite a few years in the early days of his training on construction and central station work, and was five and one-half years with the Westinghouse company. He is a native of South Carolina, and a graduate of Newberry College in Electrical Engineering of that state.

Wagner Electric Corporation of St. Louis announces the transfer of F. C. Hosimer from the home office to the Chicago branch. Mr. Hosimer entered the employ of the Wagner Company while a student engineer at Purdue University and has been employed as sales correspondent.

Graver Corporation has appointed Mr. William E. Dunbar as Southeastern sales engineer. Mr. Dunbar will be located at Florida Theatre Building, Jacksonville, Fla. His territory will include the states of Florida, Georgia and Alabama. Mr. Dunbar is no stranger to his territory nor the equipment he is selling, as he has been engaged in the water softening and filtering business in this territory for many years.

Sales Force Representatives, Manitowoc Engineering Works. Upper Row—J. A. Forsythe and J. A. Egan. Middle Row—C. H. Moore, C. C. Miller, R. A. Chadwick, E. B. Nickles and M. G. Hennessey. Lower Row—T. O. Putt, J. E. Thiell, J. W. Frain, F. C. King and J. J. Reilly

Water Works and Sewerage

Left—Intake Shaft and Forebay at Edisto River. Right—Intake Shaft and Forebay, Looking Upstream

The New Water Supply of Charleston, S. C.

Edisto-Ashley River Tunnel Driven 4½ Miles Through Marl

By J. E. GIBSON

Manager and Engineer, Water Department, Charleston, S. C.

As a result of the unprecedented droughts occurring in the southeastern states during the fall of 1926, the Commissioners of Public Works of the city of Charleston, S. C., operating the water department, authorized the department to make a study of the water supply resources of Charleston with the idea of developing an additional supply. These studies were carried out during the summer of 1927, and resulted in the department recommending the Edisto River at Givhans Ferry as the supply.

Goose Creek, the present supply source, has a drainage area of 42½ square miles. Lying immediately to the west of this drainage area is the Ashley River, having a drainage area of 245 square miles, upon which, at Bacon's bridge, there have been built a dam and an auxiliary pumping station. The Edisto River lies to the west of the Ashley River and has a drainage area at Givhans Ferry of 2,476 square miles, with the divide between the Ashley and the Edisto within ¼ mile of the Edisto River.

River Water Diverted Through Tunnel.—On account of the nature of the drainage area above Bacon's bridge—low, swampy, heavily timbered area, with marl formation lying within two to three feet of the surface—the flow of the Ashley River at Bacon's bridge reaches as low a quantity as 50,000 gallons per day, whereas the Edisto River to the west of the Ashley has an average flow in excess of 300 m.g.d. with a minimum flow probably never less than 150 m.g.d. It was proposed, therefore, to divert sufficient waters of the Edisto River into the Ashley River to produce at all times an adequate supply of water for the pumping station located at Bacon's bridge on the Ashley River. This pumping station delivers the water under a 26-ft. static head into the drainage area of Goose Creek, whence the water flows by gravity to the Goose Creek pumping station and filter plant for ultimate use. A series of levels run between the Edisto River and Goose Creek developed the fact that the fall between the normal elevation of the water in the Edisto River at Givhans Ferry and a small tributary of the Ashley River that could be reached within 4½ miles of Givhans, was 13 ft.; that is to say, the elevation of the Ashley River at the nearest point was 14 ft. and the Edisto River had a normal stage of water of 27 ft. The divide between the Edisto and the Ashley River is a high table-land with an average elevation of 60 ft. for from 1½ to 2 miles. Therefore, to divert the waters from the Edisto to the Ashley, it was necessary either to tunnel this distance or to put in a pumping station and pump the water through pipes across the table-land. The latter consideration proving prohibitory as to cost for the quantity of water required, it was determined to tunnel. This constitutes the unusual feature of the job—a 4½-mile tunnel in the low, flat coastal plain of South Carolina. The tunnel is really not a tunnel in the sense that we ordinarily think of a tunnel, but is rather a conduit as it is well below the hydraulic grade line between the two sources and acts as an inverted syphon.

Tunnel Driven in Marl.—The beds of both the Ashley and the Edisto rivers are eroded down to the marl; in fact, the east bank of the Edisto is a sheer bluff of about 30 ft. of marl formation. This marl is a semi-limestone formation that can be readily cut by sharp tools such as mattocks or picks. It is homogeneous in nature and shows very little erosion by the current. It was this condition that led Mr. McDowell, assistant manager and engineer, and the writer to decide on tunneling, as all our in-

vestigations developed the fact that the marl would withstand erosion even where the velocities were very high. Test borings were made every half-mile along the line of the projected tunnel and the elevation of the marl determined, and with this information available it was an easy job to locate the tunnel at the proper elevation to maintain a satisfactory covering of marl at all points.

Pumping Scheme.—The design contemplates ultimately carrying the tunnel to the Goose Creek pumping station, a total distance of 22½ miles. The work undertaken, however, embraced only the tunnel from the Edisto River to the tributary of the Ashley River, a distance of 4½ miles, passing under the divide between the two rivers and thence continuing with 1½ miles of open canal. The canal is really an improvement in alignment of the small tributary into which the outlet shaft of the tunnel is discharged. Water will flow from the Edisto River through the tunnel for a distance of 4½ miles, thence through improved canal to the Ashley River proper and thence down the channel of the Ashley River 8 miles to the Bacon's bridge pumping station. Here it will be pumped by Diesel-engine-driven centrifugal pumps through a 24-inch pipe line to the Goose Creek drainage basin. The present capacity is 5 m.g.d. with provision made for increasing to 10 m.g.d. when required. When this latter figure is reached, it is hoped that funds will be available to continue the tunnel work the remaining 18 miles to the Goose Creek pumping station. The ultimate capacity of the tunnel when completed to Goose Creek will be 25 m.g.d. and the fall in the tunnel from the inlet to the outlet at Goose Creek will be 18 ft. The tunnel section is horseshoe shaped, the upper half being a circle of 3½-ft. radius and the lower quarters and bottom being segments of 7-ft. radius struck from the ends of the horizontal diameter and the top of the upper circle.

Cost to Date.—Plans were completed, and bids were opened on December 5, 1927. The contract was awarded to the MacDougald Construction Co., of Atlanta, Ga., on January 6, 1928. Charles C. Case was representative owner in charge and Barry Tufts was general superintendent. The total cost of the work, exclusive of the open canal, which has not as yet been completed on account of the continued wet weather and the resulting inaccessibility, was $383,575.26, made up as follows:

Engineering, preliminary surveys, inspection during construction and overhead	$ 23,432.58
Legal expense, land and rights-of-way	10,203.12
Contract, MacDougald Construction Co.	349,939.56
Total	$383,575.26

Composition of Marl.—There were no particularly difficult engineering feats required in the construction of the tunnel. The underlying geologic formation of the coastal plain from Georgetown at the mouth of the Santee River to as far south as Savannah is marl, which occurs in the Cretaceous, Eocene, Oligocene, Miocene, Pliocene, and Pleistocene periods. The elevation of the marl formation on the Cooper River and Goose Creek is about —3, mean sea level, with a gentle rising slope toward the west until it reaches the Edisto River, where it outcrops in a sheer bluff on the east bank of the Edisto River 15 or 20 ft. above mean water level, or elevation 42 ft. above mean sea level. The marl through which the tunnel is constructed probably belongs to the Miocene period.

The analysis of the marl runs about as follows:

Sulphur trioxide	Trace
Silicon dioxide	13.04%
Iron and aluminum oxide	1.78%
Magnesium oxide	Trace
Calcium oxide	*46.16%

*Equivalent to calcium carbonate 81.76%.

Shafts and Headworks.—The contract as awarded consisted of the inlet portal shaft, the exit shaft, three intermediate shafts located about one mile apart and 4½ miles of tunnel, from a 40-ft. minimum to a 65-ft. maximum depth below the surface of the ground. The order of construction was to sink all shafts to the desired grade and then drive headings in both directions from the intermediate shafts and in one direction from the inlet and outlet shafts. The tunnel was given a slight ascending grade from each shaft heading so that any water that might be encountered during construction would drain to the shafts. Very little water was encountered. All shafts are concrete lined from bottom to surface and provided to receive stop logs so that any section of the tunnel can be isolated and unwatered if required.

The headworks consist of a concrete entrance having an opening into the river 20 ft. wide, with a minimum depth of 3 ft. at low-water stage of the river. The water will flow into this inlet, thence through racks and screens controlled by two 48-in. square sluice gates, down the inlet shaft and into the tunnel. The minimum elevation of the water in the Edisto River is taken as 23 ft.; normal, 27 ft.

Methods of Construction.—The contractor erected at each shaft a stiff-leg derrick with gasoline or air-driven hoists for lifting the muck from the shaft and tunnel, and at inlet shafts No. 1 and No. 3 erected a 1,050-ft. Diesel-engine-driven Sullivan compound compressor. These units were connected on the surface with 3½-in. wrought-iron pipe, and at each end extended to include the inlet and outlet shafts. At all shafts necessary air valves and take-off lines were connected to this air line. A small gasoline-driven electric light plant was installed for furnishing light in the tunnel and shafts. Under ground, the air lines were 2½ and 3 in. in diameter.

At first it was thought unsafe to do any blasting in the tunnel but careful experimentation after the work started disclosed that a moderate amount of

Left—Intermediate Shaft No. 3 and Spoil Bank. Right—Outlet Shaft and Spillway Just Before Completion

powder or gelatin could be used to advantage. Light charges of ½ lb. of 40 per cent gelatin in each of five holes at a depth of from 4½ to 5 ft., spaced about 2 ft. from the circumference of the tunnel, were found to remove a satisfactory amount of material without injury. After this material was removed, the tunnel section was finished to size with pneumatic spades and hand adzes. Alignment was maintained as in other tunnel construction. The muck was removed in small removable body cars over a light-rail 20-in.-gauge track to the shafts, where the body of the car was raised to the surface. Here the muck was dumped into a larger car and carried to spoil banks. Man power was used for muck cars.

Progress of Work.—Progress in driving the tunnel was made as follows:

The heading between the inlet shaft and the west heading of No. 1 shaft was holed through September 15, 1928.

The east heading from No. 1 shaft to the west heading of No. 2 shaft was holed through October 2, 1928.

The east heading between No. 2 shaft and the west heading of No. 3 shaft was holed through on the afternoon of November 1, 1928.

The east heading from shaft No. 3 to the west heading of the outlet shaft was holed through November 9, 1928.

The maximum error in alignment at meeting points was 17 in. and the minimum ½ in. We consider this exceptionally good engineering work, for the longest base line available at the commencement of the work was the diameter of the shafts, a maximum length of 11 ft., and a minimum length of 8 ft. The lapse of time between the holing through of the last shaft and the final completion of the work was taken up in the final finishing of the surface of the tunnel, completion of the concrete shafts, capping, removal of plant equipment, etc.

The marl throughout the 4½ miles of tunnel was quite uniform in character, showing no tendency to squeeze or fall. The tunnel is unlined throughout its length and has been filled with water since April 1, 1929, but has not been put into service as the rainfall has been more than sufficient to maintain the Goose Creek impounding reservoir full to overflowing.

Engineering Personnel.—All engineering work was carried out by the department, with F. B. McDowell, Jr., as engineer in immediate charge and Gabriel Cannon as resident engineer.

North Carolina Water Works Men Meet in November.—The 9th annual convention of the North Carolina Section, American Water Works Association, and 6th annual meeting of the North Carolina Sewage Works Association will be held jointly at the Sheraton Hotel, High Point, N. C., on Nov. 4, 5, and 6, 1929.

Artesian Water Supply of Memphis, Tenn.

The Geological Survey, United States Department of the Interior, has undertaken an investigation of the ground-water conditions in Tennessee in cooperation with the State Geological Survey. As a part of this larger program, about two months was spent in Memphis and vicinity during the summer of 1928 by F. G. Wells, of the United States Geological Survey. Automatic water-stage recorders were placed over representative wells and obtained continuous records of the depth to the water level in these wells. These records show with much precision the relation between the withdrawal of artesian water and the underground inflow of water to recharge the artesian reservoir. The longer the period covered by such records the more accurate are the conclusions that may be drawn. For this reason it is planned to continue observations at Memphis for several years.

Manuscript copies of a preliminary report giving the data that have thus far been obtained and such generalizations as can safely be made at this stage of the investigation, together with a map of Memphis showing the location of wells, tables of well data and chemical analyses, and illustrations, are now open for public inspection at the office of the Tennessee Geological Survey at Nashville, and at the Memphis Chamber of Commerce. This report gives a brief history of the artesian-water development of the area from 1867 up to the present time. The geology of the region is described, with particular reference to those formations that are important as producers of water. The Holly Springs and Grenada formations are the two most productive water-bearing formations in the area. The Holly Springs formation is encountered at about 450 ft. below the surface and continues to a depth of about 1,000 ft. The Grenada formation has a maximum thickness of 400 ft. and lies about 75 ft. below the surface. The Ripley formation, which also yields considerable water, is encountered at a depth of about 1,300 ft.

The total average daily pumpage from both public and private wells was 37,385,000 gal. in 1920 and remained below this figure until 1928, when it amounted to 38,600,000 gal. It is estimated that in 1928 about 2,000,000 gal. of water a day was pumped from the Ripley formation, the remainder coming from the group that includes the Grenada and Holly Springs formations.

The development of water supplies in Memphis during the last 10 years has caused an increase of over 1,000,000 gal. in daily pumpage, but as there has been a large increase in the area drawn upon by wells, the lowering of the water level has been less than if the wells had been concentrated in a smaller area. In view of the large quantity of water pumped, the loss in head is not great, and it is believed that additional supplies can be obtained, but future developments should be distributed as widely as possible. If more water is pumped the head will doubtless decline further, but for any increase that is expected in the immediate future the decline would hardly be great enough to be serious.

Analyses of water from wells in the Grenada formation show that in general it is fairly soft and has a moderately low content of dissolved mineral matter. Except for the slight trouble and expense involved in the removal of iron, water from the Grenada and Ripley formations is likely to be thoroughly satisfactory for all ordinary purposes.

New 750,000,000 Gal. Water Supply for Ford Plant

Work has been started on a 2¼ mile water tunnel from the Detroit River to the Ford Motor Co. plant at Rouge, Dearborn, Mich., to supply the expanding needs of the plant with 500,000 gal. of water a minute. This volume is 100,000 gal. a minute more than present supply which is now withdrawn from the Rouge River through the slip, the docking place for Ford ships. Ninety per cent of all the water is used for cooling purposes. This is heated up and returned to the lower Rouge River below the plant through a discharge tunnel.

The increased demand for water for manufacturing purposes followed adoption of plans for doubling the capacity of the power plant, with provisions for further anticipated expansion. Several power plant units are now being replaced by two 110,000 kw. turbine-generators, each of which alone requires 150,000 gal. of water a minute for condenser cooling.

The new tunnel, to be completed in a year, is of the gravity type and is being laid 40 ft. underground. Its inside diameter is 15 ft., and it is to have a concrete lining 25½ in. thick.

Present requirements are approximately four to six times greater than supplied by the upper Rouge River. Therefore, the balance must be drawn from the lower Rouge River which reverses the current from the discharge tunnel to the slip. This returns the warm discharge water to the slip and the constant recirculation raises the temperature 18 or 20 degrees above the average river temperature.

To overcome that objection and also to provide for adequate quantities for further expansion the company was faced with the necessity either of tapping the Rouge farther upstream and installing a cooling spray or to tap other sources. By tapping the Detroit River, more than two miles away, the company is assured of unlimited supply and will be able to use its present River Rouge system for disposal of water after having passed through the plant.

New Methods and Equipment in Filtration Plant Operation

Problems Discusssed at the Ohio Conference on Water Purification

SEVERAL new methods or new equipment were described at the 8th annual Ohio Conference on Water Purification. The discussion of one of these "The Use of Carbon Dioxide Scrubber Water for Removing Sand Incrustation," brought out some entirely new ideas on recarbonation. The notes following are taken from the recently issued report of the conference.

Use of Pulverized Quick Lime at Portsmouth

By F. E. SHEEHAN
Superintendent of Filtration, Portsmouth, O.

Lime is used at Portsmouth ordinarily to keep the carbon dioxide content down to a minimum. However, during the last few years, the phenol taste trouble has compelled us to abandon chlorine treatment for days and weeks at a time and during these periods, it has been necessary to resort to excess lime treatment to maintain a factor of safety. To obtain a causticity of about 5 p. p. m., from 2.3 to 2.5 g. p. g. CaO must be used, and with a pumpage of 7,000,000 gal. per day, this amounts to about 2500 lb. of burnt lime or 3500 lb. of hydrated lime.

Lime was first used in the hydrated form in solution feed, but the annoyance of mixing so often and the resultant dust that covered the plant caused us to resort to dryfeed machines, exclusively. In connection with these machines, large hoppers were built, from which the lime was fed to the machines. The use of hydrated lime in these hoppers was not a success as the lime occasionally arched in the hopper and did not feed at all or at other times it fed too rapidly and overflowed the machines. Accordingly we changed to the use of pebble lime which had just come upon the market. In doing so, we added a mechanical slaker. The lime dryfeeds were placed over cylindrical cast iron chambers in the centre of which were set vertical paddles. By means of bevel gears, these paddles were operated from the countershaft which ran the dryfeed machines. The pebble lime worked excellently in the hoppers and slaked quickly, but great difficulty was encountered from the insoluble cores. When large amounts of lime were fed, these cores would collect in the bottom of the slaker and stop the agitator. Accordingly we tried a car of ground burnt lime and the latter, at any rate for small plants, appears to satisfy any demand placed upon it. Shipped in either 180 lb. steel containers or 90 lb. paper-lined burlap sacks, it retains its CaO content indefinitely. Shipped in this manner, it is much easier to unload than hydrated lime which comes in 50 lb. paper sacks, the latter being easily torn and a constant source of lime dust. The ground lime is fed by the dryfeed machines as perfectly as alum, showing no tendency to arch in the hoppers or to overflow. There is apparently no need of assisting the slaking action as the lime almost immediately forms a milk of lime solution in the mixer, comparable to the action of hydrated lime used under similar circumstances. There is no heat developed when small amounts are used, but chemical tests show that no part of the lime is lost through incomplete reaction. I believe it may be used in place of hydrated lime without using elaborate equipment for slaking purposes. The cost of ground quicklime on a unit basis is somewhat less than hydrated lime. All things considered, I believe it to be the most satisfactory manner in which lime may be employed.

Discussion.—The idea that quicklime could be hydrated or put into solution quickly without evolving considerable heat was new to most of the conference members. No appreciable amount of heat is developed in the slaking process at Portsmouth where the lime is discharged into a small solution tank and from which it flows almost immediately to the mixing chambers through approximately 100 ft. of pipe. Mr. Hoover stated that the pulverized quicklime was not the only kind of lime which would slake in this way. He mentioned a kind of crushed quicklime which, after 30 minutes stirring in cold water, goes to pieces with no heat evolved.

A Small Sand Washer and Gravel Grader

By F. E. SHEEHAN
Superintendent of Filtration, Portsmouth, O.

During the last few years, all of the filter units at Portsmouth have been completely overhauled. This has been in connection with the removal of air pipes from the filters and the making of slight changes in the underdrain system to enable us to obtain a higher rate of wash. The overhauling presented no serious problem with the exception of the grading of the gravel before replacing in the filter. The sand was merely ejected to a platform and injected back into the filter. The screening and grading of the gravel by hand, however, was a slow and tedious job, and we looked about for some means of mechanical screening. After experimenting, we finally put together a shaker screen that has successfully handled the gravel from the filters. It consists of a series of screens—2 ft. by 3 ft.—mounted one above the other with the coarse screen at the top and the set of screens as a unit, suspended to swing sideways in a wooden frame. By means of an eccentric arm working from a countershaft, operated by a 3 h. p. motor, the screen was shaken about 250 times per minute and the different sizes of gravel led to separate piles by means of chutes. This shaker has done the work well, but to obtain a successful separation, the gravel had to be perfectly dry. About one-half the gravel can be ejected upon the platform. The remainder has to be shoveled out of the filter, wheeled to the platform, washed, and allowed to dry.

The idea occurred to the engineer of a concern which manufactured sand-screening machinery, who happened to watch our makeshift shaker in operation that use could be found for a self-contained unit for washing and screening filter gravel and, accordingly, he drew up a design for such a unit.

The outfit consists of a revolving screen with central shaft, operated at a speed of about 15 r. p. m., a 2 h. p. motor furnishing the power and a planetary speed reducer producing the low speed, all mounted on a structural steel frame. The gravel may either be injected or shoveled into a scrubbing chamber which is perforated to allow the sand, which is always present in small amounts, to be removed from the gravel. The sand and possibly some of the smaller sizes of gravel pass from the scrubbing chamber to the sand jacket which contains small perforations to allow the sand to pass to the collecting chamber beneath the screen. This tank also catches the dirty wash-water which may be led to the sewer from the tank by means of an overflow nozzle at top of tank. The sand is continually removed from the tank by means of a drag-line, with chain and sprocket drive operated also by the driving motor. The gravel passes from the scrubbing chamber and the sand jacket to the screen proper, which may contain three or four sections or as many as desired, depending upon the gravel to be screened and the number of sizes required. The different sizes may be led from the screen into separate piles by means of chutes.

The entire outfit, mounted on trucks, may be moved easily, in fact it could

be set up near a filter, and the entire gravel content could be removed, washed, graded and returned to the filter in a day's time. The machine, as described, will handle about 100 yds. of gravel in a day. It appears that, since periodic overhauling of filters is absolutely necessary, such a unit as the one described could well be an integral part of the modern water purification plant.

Experiment on Using Broken Stone Instead of Gravel in Filter Bottoms

By O. F. SCHOEPPLE
Chemist-in-Charge, Sandusky, O.

One of the filters at the Sandusky plant gave some little trouble with a very uneven distribution of wash water, the development of hard spots and inversion of sand and gravel. In checking over the filter material in this unit it was found that there was but 9 in. of gravel of which only 2 in. was of a size greater than ½ in. Some little difficulty was experienced in finding nearby satisfactory gravel in the larger sizes. This suggested the use of limestone.

Before it was decided to increase the gravel depth by the use of limestone in the filter bottom an inspection of the crushed limestone in the bottoms of the sewage filters at the Ohio Soldiers and Sailors Home at Sandusky was made. This stone has been in place for something like 30 years and inspection of it indicated that it was in practically the same condition as when placed.

In the large limestone quarries just south of Sandusky are found several grades of limestone all of dolomitic character but differing considerably in hardness. The type selected for this experiment was the same grade that was used on the Akron sewage plant work. The size used was 2½ in.

One filter was reconstructed for experimental work and 4 in. of 2½ in. hard dolomitic limestone was used on the New York Continental Jewel filter bottom. On this stone was placed the original gravel and then the filter sand.

This reconstructed filter was placed in service on June 12, 1928, and to date has given no trouble with gravel inversion. It has developed no hard spots and shows a very even distribution of wash water. No examination of the stone in the filter bottom has been made to date. It is expected to take samples of the stone every year for comparison with the condition of the original stone when added.

Discussion.—The specification calling for round gravel in preference to irregular shaped crushed rock in filter bottoms are wrong in his opinion Mr. Burgess stated. The irregular particles become bedded, and upon examination you can find that in many cases they have not moved after a filter is washed. He cited the case at Wilmington, Dela., where irregular shaped rock was used in the filter bottoms because they would stay in place better than the round gravel.

Smith reported that crushed stone had been in place in the filters at the Lima State Hospital filter plant for two or three years. The rock was put in when, in overhauling the filters, it was decided to increase the depth of the gravel. As no gravel was immediately available some crushed stone was used. Very good distribution of wash water has been obtained since.

If the use of crushed limestone proves to be satisfactory for replacing the larger sizes of gravel in filters it will go a long way toward solving the problem of obtaining satisfactory supporting material for the sand at many places in Ohio.

Use of Carbon Dioxide Scrubber Water for Removing Sand Incrustation

By J. M. MONTGOMERY
Superintendent of Waterworks, Piqua, O.

THE method of treatment of the water supply at Piqua was described in full at the Seventh Annual Conference. It will be remembered that following the heavy lime treatment, the water is treated with carbon dioxide so as to reduce all the hydrate and part of the carbonate alkalinity to bicarbonates. That is, a considerable amount of carbonate alkalinity is left in the water influent to the filters. This, of course, has resulted in some incrustation of the sand.

The carbon dioxide plant consists of a coke burning furnace, a scrubber and drier and a compressor to force the gas through a grid system in the carbonation chamber. Water used in scrubbing the gas has been run to waste until recently when the idea was conceived of passing this scrubber water through one of the idle filters, for the purpose of removing the incrustation from the sand. The scrubber water is highly charged with carbon dioxide and it contains some sulphuric acid which also aids in removing the incrustation. It is introduced into the underdrains of the filter and allowed to pass up through the sand and into the wash water troughs and to waste. The alkalinity of some samples of this scrubber water after it passed through the filter has been as high as 1000 p. p. m. This shows that it is removing the incrustation. Unfortunately insufficient analytical data are available to tell just what can be accomplished, and for this reason it is not known whether it is more economical to treat the sand in this manner or to allow the incrustation to accumulate for several years and to then replace the sand. That problem will be worked out.

Discussion.—Considerable interest was manifest in Mr. Montgomery's description of his method of removing incrustation from sand. Mr. Woodward of the Carnegie Steel Co., raised the question as to whether this method of treatment would remove magnesium carbonate incrustation as readily as it would calcium carbonate. Mr. Montgomery replied that the heavy lime treatment employing 40 p. p. m. causticity precipitated practically all the magnesium in the form of magnesium oxide, which is very flocculent, and in character very similar to alum floc. There is very little magnesium left in the water which can incrust the sand. Mr. Cameron inquired as to the corrosive action of the scrubber water on the piping in the underdrain system of the filter. It seemed to be the opinion of many present that undoubtedly some trouble might result from this practice of introducing scrubber water into the underdrain system of a filter, especially if the scrubber water contained much sulphur. Sulphur can be very largely removed from the scrubber water by replacing the coke in the scrubber with limestone. It is planned, Mr. Montgomery said, to put limestone in the scrubber to remove the sulphur gases. Mr. Hoover, in summing up the points brought out by the paper, and in the discussion, said that he feared that we were getting away from the original purpose of recarbonation. The original purpose was to prevent incrustation. The next development was to over-treat the water with lime, and then apply only enough carbon dioxide to reduce hydrate alkalinity, but leaving normal carbonates in the water. This method of treatment still leaves the water in an unstable condition, and causes incrustation of the filter sand. If it is desired to obtain low alkalinities in the recarbonated water, he said, carbon dioxide treatment should be carried out in two stages; the first application should be at a point near the outlet of the mixing chamber. The quantity should be just sufficient to precipitate magnesium which is flocculent and will carry down the finely precipitated calcium carbonate. The second point of application should be at the end of the settling basins just before filtration. A water treated in this way will have a low alkalinity and will not incrust the filter sand.

Mr. Clark commented on the idea of double recarbonation by saying that in the design of the new water purification and softening plant at Fremont, provision had been made for three points of application for carbon dioxide. The first point is between the clarifier and the sedimentation basin, hoping by application of carbon dioxide there to obtain better deposition of the precipitate formed. The second point is in the regular recarbonation chamber between the sedimentation basins and the filters. A third point of application has been provided in the clear well. However, Mr. Clark stated that he questioned how

far treatment at this point was desirable or necessary.

Regarding the concentration of carbon dioxide in the gas used in various recarbonation plants, the question was asked as to what was the thought underlying the higher concentration of carbon dioxide. It was answered by Mr. Hoover as follows: "We have at Columbus an air compressor which pumps 800 cu. ft. of gas per minute. If this gas contained only 5 per cent carbon dioxide instead of 20 per cent, it would be necessary that we have a compressor of four times the capacity. In other words one which consumes four times as much power."

Liability for Water Borne Diseases

Courts have held on numerous occasions that the owner of a water supply, whether a municipal or private concern, was liable for damages caused by sickness resulting from the use of a polluted water furnished by him. The following synopsis of such decisions was given in an appendix to the final report of the committee on Cross-Connections of the New England Water Works Association:

Green v. Ashland Water Co. (1898) 101 Wis. 258: "If defendant knew, or from the situation ought to have known, the water it is distributing was dangerous for domestic use, from some cause not discoverable ordinarily by the exercise of reasonable care, it owed the duty to its customers of disclosing that danger, and a failure so to do, knowing that such customers were liable to use the water through ignorance of its character, was a fraud in law, rendering the defendant liable to legal damages to any person injured by such fraud without fault on his part, and it was also a failure of duty amounting to actionable negligence as well, to which the same liability is incident." Five thousand dollars verdict involved.

Lockwood v. Dover (1905) 73 N. H. 209: Negligence was alleged in that defendant municipal corporation failed to clean out its water pipes or to provide means whereby they could be cleaned out, and that in consequence thereof foreign and decayed matter became lodged in the city's pipes, entered the pipes leading to the plaintiff's dwelling and was there drunk by the plaintiff's intestate, causing him to sicken and die. It was held that the defendant was liable.

East Grand Forks v. Luck (1906) 97 Minn. 373: Based upon a study of the following cases: Reed v. City of Anoka, 85 Minn. 294, 88 N. W. 981; Walla Walla City v. Walla Walla Water Co., 172 U. S. 1, 19 Sup. Ct. 77, 43 L. Ed. 341; Illinois Trust & Savings Bank Co. v. Arkansas, 76 Fed. 271, 22 C. C. A. 171, 34 L. R. A. 518, Judge Elliot said: "When the municipality enters the field of ordinary private business, it does not exercise governmental powers. Its purpose is not to govern the innabitants, but to make for them and itself private benefit. As far as the nature of the powers exercised is concerned, it is immaterial whether the city owns the plant and sells the water, or contracts with a private corporation to supply the water. It is not in either case, exercising a municipal function. . . . When a municipality engages in a private enterprise for profit, it should have the same rights and be subject to the same liabilities as private corporations or individuals.

Keever v. Mankato (1910) 113 Minn. 55: "When a municipality voluntarily engages in selling and distributing water to customers for its local advantage or profit, it enters the field of ordinary private business, and has the same rights and is subject to the same liabilities as private corporations or individuals with respect to damages from impurity of the water. . . . It is obvious that a sound public policy holds a city to a high degree of faithfulness in providing an adequate supply of pure water. Nor does it appear why the citizens should be deprived of the stimulating effects of the fear of liability on the energy and care of its officials; nor why a city should be exempt from liability while a private corporation under the same circumstances should be held responsible for its conduct and made to contribute to the innocent persons it may have damaged. Five thousand dollars awarded.

Jones v. Mount Holly Water Co. (1915) 87 N. J. L. 106: "Water is a necessity of life, and one who undertakes to trade in it and supply customers . . . is bound to use reasonable care to see that whatever is supplied for drink . . . shall be reasonably pure and wholesome, and that negligently furnishing water which is deleterious to that human body or health will furnish a valid cause of action to a customer injured by the use of the water." "Actual notice or knowledge of the unwholesomeness of the water of the defendant company was not an essential element to be proven in order to establish the defendant's liability; it was sufficient if there was testimony tending to show that the defendant, in the exercise of reasonable care, might have discovered the unwholesomeness and dangerous condition of the water." Seven hundred fifty dollars awarded.

Vennen v. New Dells Lumber Co. 154 N. W. 640: The facts in the case were briefly these; The employing company had a dual water supply in its factory; one source obtained from the city mains, the other from a nearby stream which was badly polluted. The two water distribution systems were connected by a pipe in the boiler room protected by a Globe valve reinforced by a check valve set against the polluted supply. A number of employees were in the habit of obtaining drinking water from a faucet in the boiler room which was located so that the polluted river water could reach it. Subsequent to the epidemic of 13 cases of typhoid fever and two deaths, the valves were examined and found leaky. The court held on the demurrer of the defendant that typhoid fever was a compensable accidental injury. Sued for $20,000.

It is significant that in another case—Alex Vander Leest v. John Hobert Company, Industrial Commission of Wisconsin Workmen's Compensation 10th Annual Report, July 1, 1921 to June 30, 1922, page 59 it was held by the Industrial Commission that compensation was due nineteen employees of the company who had contracted typhoid fever by use of water from a polluted well of the company. This case, however, was not carried into the courts. Compensation awarded $2,233.61, medical aid $1,742.94. Total $3,976.55.

Stubbs v. City of Rochester (1919) 226 N. Y. 516: One seeking to hold a city liable for injury by typhoid fever, alleged to have been contracted from defendant's polluted water system, is not bound to eliminate all other possible causes of the disease to establish defendant's liability. That a city's contaminated water supply was the source of typhoid fever in a citizen may be found from the fact that he drank water near the point of contamination, that some sixty (60) other cases developed in that vicinity, that his habits were such as to tend to exclude another probable source, while his physician testified that such contamination was the source of his illness.

Canavan v. City of Mechanicsville, 128 N. E. 882: A private water company or a municipality is not an insurer, nor liable as a guarantor, of the quality of the water it furnishes to its customers by the customary means of pipes and faucets, and cannot be held liable for injuries caused by impure water furnished by it, unless it knew or ought to have known of the impurity. Its duty is that of exercising reasonable and commensurate care and diligence in providing an adequate supply of wholesome water at all times.

In the case above cited the court decided that the complaint stated a valid cause of action against the defendant city on account of typhoid fever contracted by plaintiff and his children from drinking impure water.

Roscoe v. City of Everett, 239 Pacific 831: In discussing the case the court said: "It is sufficient to say that the evidence discloses that on April 11, 1923, a six-inch main was laid to connect two laterals, and that when the connection was so made it permitted free circulation of water to the city users in the district served, and also better service to the Eclipse Mill Company. At the time this connection was made, there was a by-pass which had existed for a great many years. With the making of the connection there was no longer any need for the by-pass. This by-pass had in it what is known as a gate value A—a valve worked by hand, and which when closed, effectually prevented water from passing through the pipe." . . . "There was evidence that the city never inspected the valve in the by-pass from the date of its installation." . . . "The ease with which the valve could be sealed or by-pass removed and the eminent danger to be apprehended by failure so to do are strong factors in the question of the city's negligence." Award $60,000.

Water Company Gives Prizes to Employees for Suggestions Improving Service

Henry W. Drury is the winner for 1929 of the prize of $200 in gold awarded annually to an employe of the Hackensack Water Co., Weehawken, N. J., for the best suggestions to improve service, it is announced by the president of the company, Nicholas S. Hill, Jr.

Four suggestions made by Mr. Drury, who is the commercial agent of the company, have been adopted by the company's departmental heads as the basis of new and better practice.

One of Mr. Drury's proposals was that plumbers be permitted to set and reset meters on customers' services. This has been approved by the Master Plumbers' Association.

Substitution of a simpler form of office record of the establishment of service than the present customers' application blank was another suggestion, which is now being worked out.

A third suggestion was that a simple system of customers' credit rating be established, and that the system of collection of accounts be rebuilt around this rating to the end that collectors' calls may be eventually eliminated. Rating is now well under way, and the result has been better collections with less calls and improved public relations.

Fourthly, Mr. Drury proposed the simplification of the inspection of new meter installations by meter readers.

These suggestions were among many submitted by other employes to the bureau of new ideas, established by the company about three years ago as a part of a general program of service betterment. Previous suggestions, according to Mr. Hill, have proved of great value to the company and to the public.

"All employes were requested to make suggestions which, in their judgment, would increase efficiency of operation and extend the usefulness of the company," Mr. Hill explained. "The response has been both emphatic and enlightening. This year many of the suggestions were so meritorious that the selection of the best was no easy task.

"The bureau of new ideas is developing as a constructive force in anticipating the water supply needs of Bergen and North Hudson Counties. Its operation means increased vigilance on the part of the entire organization of the Hackensack Water Company in the public interest."

Encouraging Watering of Trees.—In an attempt to encourage residents of Kearney, Neb., to preserve their trees, the city water works cut the excess water rate in half for the month of September.

The New Sewage Disposal Works of Highlands, New Jersey

Design and Construction Features of Plant for Fluctuating Load of 2,500 to 15,000 People

By LESTER H. BURNS

ON the Sandy Hook Bay, just north of the Navesink River, lies a range of hills overlooking the Atlantic Ocean. This range of hills colloquially referred to as the "Highlands," is the highest point on the Atlantic Ocean between Maine and Florida. The entire section, combining its wide, sandy beaches and the exhilarating salt sea air with the restfulness of wooded slopes, has been generously favored by Nature. Small wonder, that each year hundreds of thousands of people are attracted from the congestion of the nearby cities to enjoy the beauty of the "Highlands" and the healthful recreations which they offer.

These great numbers of people coming during the short summer season greatly overtax the facilities of the section for administering to the elementary needs of the normal population. During this annual influx of summer visitors, many problems face the governing bodies of the towns comprising the "Highlands." The most pressing question at present is the proper disposal of waste and the elimination of the pollution suffered by the beaches and surrounding waters. This problem is a result of antiquated sewage systems.

The taxpayers of the "Highlands" towns realize that the evils resulting from water pollution will cause serious economic losses if left unchecked; and they realize that these conditions must be changed. As a result, new sanitary systems are being installed to treat this waste by the most modern and approved methods of sewage disposal.

The Borough of Highlands, N. J., by the installation of a modern, well equipped sewage disposal works, designed by Remington & Vosbury, consulting engineers of Camden, N. J., is the most recent town in the ever-growing chain of communities that have taken steps to eliminate the noxious conditions, the result of the old methods of sewage disposal. The system under construction has been designed to meet not only the requirements of the normal population of 2,500, but also the needs of a transient population, which during the summer season reaches a total approximating 15,000 people.

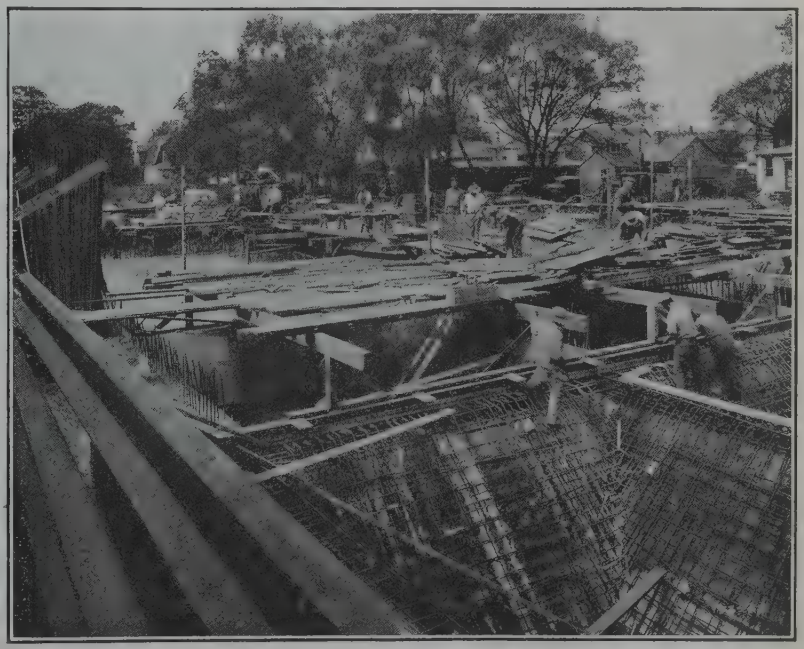
The contract for the construction of the system was awarded to Mahlon Averill, general contractor of Newark, N. J. The construction is under the supervision of B. B. Skinner, and the engineer is Mr. MacDonald of Remington and Vosbury. When completed, the entire disposal plant will embody all the refinements which modern engineering skill has developed. The gravity septic tank principle will be employed to treat the waste.

General Features of Plant.—The system consists of the old network of sewers, which carry the influent to two small pump houses at either end of the town. From these points it is pumped through a 20-in. main leading to the disposal plant, which consists of a large pump house and four septic tanks of four hoppers each, where the waste is treated.

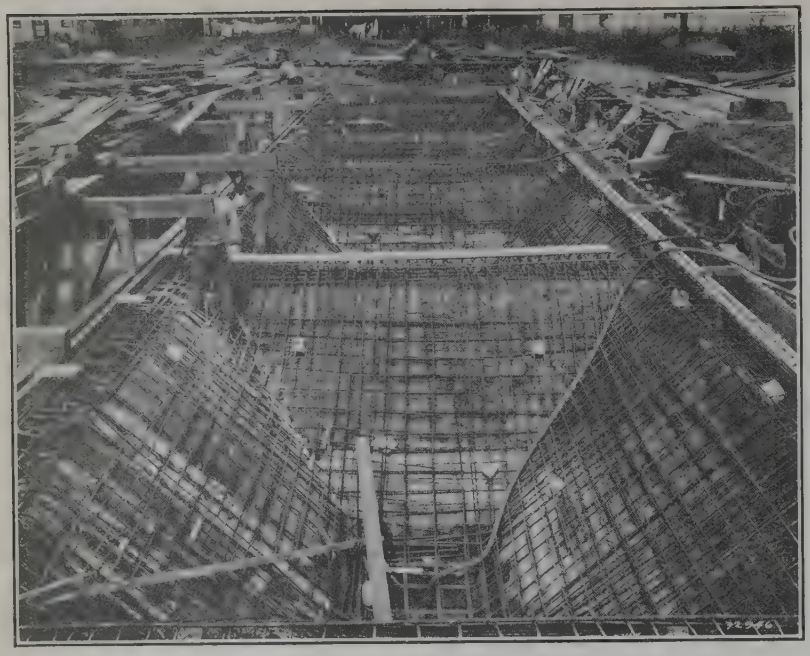
As is usual in residential towns within commuting distance of large industrial centers, the rate of flow in the sewers has definite hourly variations. This factor was given very serious consideration by the designers of the plant. To meet conditions, automatically controlled pumps will be installed in the main pump house to conform to the rate of flow in the sewers. These pumps, two in number, will have different capacities, and both will be the variable-speed type. The smaller pump has a minimum capacity of 200 g.p.m., which can be automatically increased in steps of 100 g.p.m., to a maximum capacity of 800 g.p.m. The larger of the two pumps will have a minimum capacity of 600 g.p.m., with a variable capacity by which the rate of flow can also be increased in steps of 100 g.p.m. to a maximum capacity of 1,200 g.p.m. Both pumps will have a depth increment of 3 in. against a 20-ft. head and will be controlled by variable-speed motors.

Automatic Control.—To effect economy in operation, the motors will be automatically controlled by a float in the sewers, and will require the attention of only one attendant, whose main duties will be to care for the moving parts, keeping them greased, oiled, and in good working condition.

When the influent reaches the main pump house, it is pumped to the hoppers of the septic tanks, through sherrardized V-notch weirs. Automatic valves control the amount of influent which each septic tank will receive, and will prevent the overloading of the tanks nearest to the pumps by the even distribution which they will effect. Once in the septic tanks, the sludge settles by gravity to the bottoms of the hoppers, whence it is pumped to the sludge drying beds above. In each hopper is sludge handling equipment for



General View of Construction Operations for Sewage Disposal Plant of Highlands, N. J.



View of Excavation Showing ¾-in. Steel Reinforcing for Sludge Hopper Construction

pumping the sludge to the drying beds above. This consists of a footpiece having a capacity of 300 g.p.m. of sludge, with a pipe submergence of 14 ft. and a total lift of 20 ft. The air consumption for lifting the sludge will be approximately 2 cu. ft. of air per cubic foot of sludge, but will not exceed this figure. The sludge equipment will be operated by a self-contained motor, operating a 3-in. portable diaphragm pump. Each sludge pump will be surmounted by a cast iron bell to effect an even distribution of the sludge over the sludge drying beds.

The sludge drying beds will consist of a layer of hard, durable, rounded gravel of high specific gravity, and on top of this will be placed a layer of clean sand of .30 to .50 millimeters, with a uniformity and coefficient of 3.50. The underdrain of these beds will be constructed of 8-in. glazed terra cotta half-tile connected to a cast iron drain, to allow the liquid from the drying sludge to flow into the effluent in the septic tanks.

The effluent will flow by gravity from the septic tanks through a vacuum solution manual feed chlorinator, having a maximum capacity of 200 lb. and a minimum capacity of 20 lb. per 20 hours. From the chlorinator it will flow through a 16-in. main to the outfall in the ocean—a distance of approximately 3,000 ft. To clear the channel of the Navesink River, which lies between the plant and the outfall in the ocean, the sewer will have a drop and rise of 25 ft.

The superstructure of the main plant will be of greenhouse construction to allow plenty of light and air for drying the sludge in the sludge beds.

Handling Excavation in Wet Ground.—In the construction of the septic tanks and main pump house, difficulty was experienced in keeping the excavations free of water. This was due to the proximity of the plant to the ocean and the formation of the soil. The top layer, from plus 4 ft. to minus 1.5 ft., consists of an old marsh with many fibrous roots. This layer cuts easily and remains firm after cutting. At minus 1.5 ft., clean, coarse sand is encountered fairly free from water at this point, but becoming more waterbearing down to minus 6.25 ft. Here the marl, because of its hardness and consistency, does not allow the water to drain off, and, as a consequence, forms a pocket for the water. This condition makes the lower part of the sand layer very wet; hence when excavations reached this point, the wet sand, with its tendency to slide, was a constant threat to the sides of the excavations.

Before actual digging started, a large sump hole was dug at the highest level of the ground, outside the foundation limits, to prevent the surface water from draining into the excavations. To keep the excavations as dry as possible, once digging started, 130 well points were driven with a water jet to minus 14 ft. The well points were spaced on 3 ft. centers and 4 ft. outside the foundation limits. They were connected to a 5-in. header by flexible hose. A Marlow centrifugal pump, having a capacity of 500 g.p.m. and operated by a 12-hp. Le Roy motor, was in turn connected to the header. The prime for this pump was maintained by a Marlow 3-in. diaphragm pump. The arrangement kept the excavations fairly free of water.

Prior to excavating for the hoppers of the septic tanks, 25-ft. piling with 10-in. butts was driven to minus 22.5 ft. The piling was yellow pine, calculated for a load of 10 tons. For each hopper 22 piles were driven with a drop hammer. The piling drove easily until the marl was reached at minus 6.25 ft., and from that point the driving slowed up noticeably because of the hardness of the marl. A water jet with a pressure of 100 lb. was tried as an aid to driving the piling, but this proved to

The 5-in. Header and Well Point Connections for Dewatering Operation

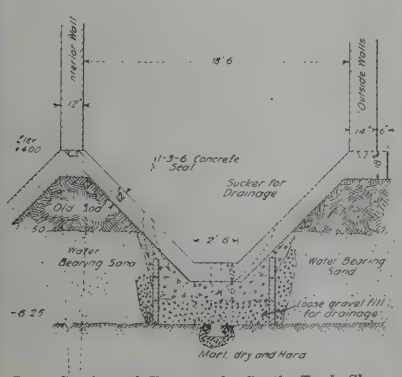
be of little aid in penetrating the marl. As a result, the piling was driven dry.

As the excavating proceded to a depth of minus 6.25 ft., no serious trouble was encountered; but when digging went beyond that depth, the sand still contained enough water to give serious trouble. The pumps, working continuously night and day for four weeks, could not remove this difficulty, as a consequence the sand, still fairly wet, had a tendency to slide into the bottoms of the excavations.

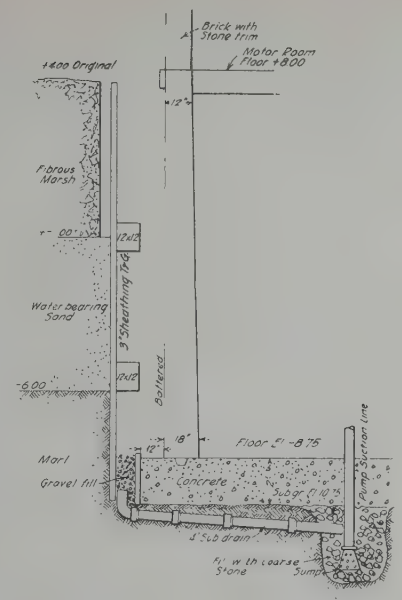
Method of Preventing Wet Sand Seepage.—To overcome this sliding action, several methods were employed, all proving more or less unsatisfactory until the expedient of using gravel was tried. In the pump house excavation, where a vertical cut was required, sheeting could be used, but on account of the 45 deg. angle of the hoppers, sheeting could not be employed here, and the problem of keeping the wet sand in place was more difficult.

For the pump house, 3x12 tongue-and-groove sheeting was driven to minus 14 ft., 2 ft. deeper than the cellar bottom. This sheeting was driven for a distance of 8 ft. through the hard marl with an Ingersoll-Rand CC-35 sheet pile drive, the air for which was supplied by an Ingersoll-Rand portable compressor. At minus 12 ft. the cellar bottom was reached, but in spite of the fact that the sheeting went to minus 14, the wet sand kept slowly oozing through. To stop this seepage, a 1-ft. trench was dug along the inside of the sheeting and was filled with gravel. A 4-in. sub-drain ran from the gravel to the center of the excavation, where it emptied into a sump hole. A suction line connected to a centrifugal pump was placed in the sump hole and then the hole was filled with gravel. This method succeeded in keeping the cellar bottom free from water.

Preventing Sliding of Wet Sand.—Obviously, because of the dissimilarity in construction, an entirely different method had to be devised, for stopping the sliding action of the wet sand in the hoppers. The method finally decided upon by Mr. Skinner, which proved successful, consisted in making a hole 2 ft. deep and 6 ft. across at



Cross Section of Hoppers in Septic Tank Showing Method of Sealing Bottoms



Cross Section of Pump House Foundation Showing Method of Draining Cellar Bottom

the bottom of each hopper. The sides of this hole were lined with 2x8 tongue-and-groove sheeting placed on edge, and laid parallel to the bottoms of the hoppers. Shallow holes were dug at the top and back of this sheeting and filled with gravel. As the weight of the gravel caused it to sink, more was added until the gravel extending from the top to the bottom of the sheeting formed a curtain between it and the wet sand.

A sucker line for draining was placed in the center of the hole and gravel to a depth of 6 in. placed around the sucker. The sucker, which operated continuously, drew off the water and kept the water level below the top of the gravel. It was in operation until after the concrete seal had been poured and had set. The seal consisted of a 1:3:6 mixture. It was poured to a depth of 6 in. on the layer of gravel and also along the sides of the hoppers to a height of 1.5 ft.

This seal effectually checked the seepage of the sand and water into the hopper bottoms. Work then proceeded rapidly, as no further difficulty was experienced from seepage. The walls of the hoppers were poured with a 1:2:4 mixture reinforced with steel bars. The weight of the steel used for each hopper averaged 2 tons.

Company Operates 31 Alabama Water Systems.—The Alabama Water Service Co., which recently acquired the properties of the Consumers' Water Co., in Alabama, now operates 31 water works in the states. The Alabama Water Service Co., is a subsidiary of the Federal Water Service Corporation, which through its subsidiaries furnish water for domestic and industrial purposes to numerous cities and towns throughout the country having a total estimated population of more than 2,380,000. Federal's properties are distributing more than 270,000,000 gal. of water a day through 5,350 miles of mains, not including recent purchases.

Some New Jersey Municipalities.—Two municipalities in New Jersey consist of golf courses, one is an airport, another has a population of 10, and a fifth is credited with 12 inhabitants.

Driving Piles with Sheeting Hammers and Portable Compressor

Collection and Utilization of Gases

Economic Phases of Use of Gases from Sewage Sludge

By DR. ANTHONY J. FISCHER
Engineer, The Dorr Co., New York

GASES produced by the digestion of sewage sludge have been collected and utilized since as early as 1907. Up until 1925, however, little thought had been given to the economic aspects of this problem. Then when various investigators demonstrated that with proper temperature and control, digestion capacities could be cut approximately in half there was a renewed interest in the collection of gas for sludge heating.

Amount of Gas Produced.—In general, laboratory experiments have shown that an average American domestic sewage will produce 530 c.c. of gas per gram of dry solids if thoroughly digested. Indications are that various physical and chemical factors do not affect this total production, although they do affect the rate of production. The chief controlling factors are temperature seeding, pH value, stirring, concentration, and character of sewage. Inasmuch as we are interested chiefly in the rate of gas production in actual plant operation, these factors are of vital importance. If, for example, a tank has sufficient capacity to take care of a 60-day supply of raw sludge containing 5 per cent total solids, with 75 per cent volatile matter, we could expect to obtain 90 per cent of the gas, provided we maintain a temperature of about 75° F., a pH value of about 7.5 and an amount of ripe sludge equal to at least 20 times the daily addition of raw slude on a dry solids basis. Lowering the temperature, pH value or amount of ripe sludge will cut down this percentage considerably. Stirring has a beneficial effect and will increase the rate of production.

Comparisons of daily production on a per capita basis mean very little because the amount of gas will vary with the strength of the sewage and the removal of suspended solids by the settling units. Taking an average domestic sewage containing 200 p. p. m. suspended solids, we can safely assume a 50 per cent removal for primary settling only, 75 per cent for a trickling filter plant and 90 per cent for an activated sludge unit. Under proper conditions, therefore, we should obtain a daily gas production of 0.64, 0.96 and 1.15 cu. ft. per capita, depending on the method of treatment.

Composition of Gas.—The composition of the gas will, of course, vary depending on the character of the sewage. Gas from material high in carbonaceous materials, such as screenings, will give a low methane content. The average gas, however, may be safely assumed to contain about 70 per cent methane, 25 per cent carbon dioxide, and 5 per cent nitrogen. As the heat value of the gas is directly proportional to the methane content, the heat value can be estimated to be 700 B. T. U.'s per cu. ft. This assumes the absence of hydrogen which is present only under abnormal conditions. Other hydrocarbon gases are present in so small amounts as not to have any appreciable effect.

At the present time nearly every tank with gas collection facilities is of the separate digestion type. As a rule, tight concrete covers for these tanks are favored as this type of construction allows covering with earth which is highly desirable during cold weather. They also insure against any loss of gas through leakage. Practically all the covers have a slight slope and have the underside submerged. This has the advantage of preventing the accumulation of gas in the tank and hazard of explosion; it also causes the scum in the tank to be submerged, under which conditions it digests more readily instead of forming a thick hard crust through which the gas has difficulty in escaping.

Gas Collection System. — Modern practice favors a gas collection system consisting of a gas dome, condensation trap, meter, flame trap and pressure relief trap for small installations. For large plants a gas holder might be desirable.

Considerable attention has been paid to the design of gas domes. In general, high separate seal domes are desirable because they prevent the loss of gas if for any reason the liquid level in the digestion tank is lowered, and they also lessen the chances of gas line clogging by scum rising in the dome. German practice favors the use of a scum rack or screen to prevent clogging by scum. It has been found, however, that these racks clog quickly and their use is questionable. The best method of eliminating this troublesome feature of gas collection is by draining off the scum through a line running to the dome. Spraying water through nozzles connected to the gas lines has also been tried, but was found to afford only temporary relief. Whether or not sprays are used, however, there should be connections available for flushing back the gas line between the condensation trap and the gas dome.

In cold climates insulation of the gas line is absolutely necessary; otherwise, freezing of condensate will cause clogging. The condensate should be collected and drained off periodically at the low point in the line before the gas enters the meter.

In order to prevent a possible backflash in the line, a safety flame trap should be provided. This trap should be located between the source of supply, whether it be a gas holder or the digestion tank, and the point of utilization. Two methods of accomplishing this purpose are in use: (1) A water seal, and (2) a wire gauge arrangement similar to a Davy safety lamp. It appears that either of these will afford adequate protection against explosions.

The pressure relief trap should be connected in front of the flame trap. It consists of an ordinary closed tank partially filled with water and connected so that when the gas pressure exceeds the submergence of the entrance pipe, it automatically by-passes through another pipe connected to the top of the tank. This will prevent the building up of pressure in the line should the use of the gas be discontainued. It is also of value where the gas is put to two separate uses, as the amounts sent to each point of utilization can be regulated by varying the submergence of the entrance pipe.

Utilization of Gas.—At the present time in this country, gas is being collected and utilized chiefly for sludge heating. This not only allows more economic construction by cutting the digestion capacity in half, but also does away with odor nuisance. In only one plant is there an attempt being made to heat the sludge in an Imhoff tank. All others are of the separate digestion type. At one plant, not yet in operation, the gases will be used as a source of heat in glass-covered sludge beds to facilitate drying during the winter months; at another, it will be used for burning screenings. In the past, the gas has been used successfully for heating small buildings. This is not being done at present to any great extent.

The use of gas for power has been shown to be entirely feasible by large scale tests. There is a renewed interest in this method of utilization, especially in view of the fact that the gas obtained is more than sufficient to maintain an average yearly temperature of 75° F. At a number of plants where the sewage is pumped, all or a part of the gas will be used for this purpose.

The disposal of activated sludge by digestion has also opened up another field for the use of the gas: that of operating the air compressors. This is already being done at the Sugar Creek plant at Charlotte, N. C. Gas being obtained from the digestion of combined raw and activated sludge amounts to about 30,000 cu. ft. a day and is used to run the compressors for about seven hours each day.

Hatfield estimated that 14 cu. ft. of gas obtained from the Imhoff tanks at Decatur would generate one brake horsepower hour. On this basis, figuring on 1.15 cu. ft. of gas per capita per day, 820 b. h. p. hours could be generated by the digestion of sludge from a contributing population of 10,000 Assuming that the power required for aeration were 25 h. p. per m. g. d., more than enough power would be available. In warm climates there would be a possibility of having sufficient gas both for sludge heating and for aeration.

Cost of Sewage Works Operations

Data for the Treatment Plant of Baltimore, Md.

By C. E. KEEFER

Engineer of Sewage Disposal, Bureau of Sewers, Baltimore, Md.

THE keeping of accurate and detailed cost data of the maintenance and operation of sewage works is a matter of prime importance for many reasons. These records are of special value to the plant superintendent, as they enable him to compare one year's costs with another. Furthermore, where plans are being considered to replace a portion or all of the plant with other treatment units, a more logical decision can be reached if accurate operating costs are available for study and comparison. These costs serve a wider field if they are published, and thus become available to sewage works superintendents and engineers. In view of these facts it has been the policy for a number of years at the Baltimore sewage works to prepare detailed cost figures. Although the methods followed in keeping these records are essentially the same as for other municipal or private undertaking, the general principles involved will be briefly presented. Tables of segregated costs are given covering the operation of the Baltimore plant.

Generally speaking, there are two items which, when added together, give the total cost of sewage treatment. The first of these is the fixed charges, which include the interest on the original investment and the depreciation of the improvement. The second item, with which the sewage works operator is particularly concerned, covers operating and maintenance costs.

Interest and Depreciation Charges.—The first cost of a plant is usually known at the time it is put into operation. This cost should include not only the money paid contractors for construction expenses but also such items as the cost of the property on which the plant is built, engineering and architects' fees, administrative and overhead expense, discount on the sale of stock, and other preliminary expenses. In case it is impossible to obtain some or all of these expenditures the sewage works operator should prepare an estimate of the total cost of the plant. With this cost established, together with the rate of interest and the par value of the stock, which is sold to finance the project, it is possible to calculate the annual interest charge.

From time to time improvements—perhaps of a minor nature—will be made. The cost of these should be added to the first cost of the plant even though the funds allotted for the work were originally intended for operation and maintenance purposes.

To determine the annual depreciation charge it is necessary to assume some future date when the sewage plant will have to be rebuilt because of obsolescence or because of its deteriorated condition. The progress that has been made during the last five or ten years in sewage treatment would indicate that many sewage works will have to be rebuilt because of obsolescence rather than because their useful life has terminated. For this reason it becomes difficult to estimate depreciation charges. As indicated in Table I the useful life of the Baltimore sewage works has been assumed to be 33⅓ years. A considerable portion of the plant has now been in service for 17 years, and it is believed that a large part of it would give service for another 30 or 40 years. It is likely, however, that future advances in the science of sewage treatment will not justify continuance of the present method of treatment at Baltimore for that length of time. In fact, plans embracing extensive changes are now being prepared.

Calculating Depreciation.—With the useful life decided upon the next procedure consists of selecting the most desirable method to follow in calculating the depreciation. Several ways of determining this charge are available, such as the straight-line method, the diminishing-value plan and the sinking-fund plan. These three methods will not be discussed other than to say that each possesses certain advantages. It would seem most desirable to use the sinking-fund method for determining the depreciation of public improvements. This plan consists of setting aside each year a sum of money so that at the end of a predetermined time—the estimated life of the improvement—the sum total, including the accrued compound interest, will equal the first cost of the project less its scrap value. The annual installment, "*I*" (depreciation charge) necessary to set aside for a term of "*n*" years at an interest rate of "*i*" to provide a sinking fund "*S*" can be expressed by the formula

$$I = \frac{Si}{(1+i)^n - 1}$$

After the fixed charges have been calculated, it then becomes necessary to determine the annual running expenses of the plant.

Operation and Maintenance Charges.—The sewage works superintendent desires to know not only the total cost of operating his works but also the cost of running the various treatment units of the plant. This information can be obtained by assigning charge numbers to each phase of the operation, such as screening, grit removal, sedimentation, oxidation, sludge digestion, sludge drying, and maintenance of grounds. All money expended, both for labor and materials, can then be properly segregated. In order that the segregations may be intelligently made at those plants where electric power units are

* Estimated.

used, wattmeters should be provided to register the power consumption at the various parts of the plant.

It is frequently desirable to keep operation and maintenance costs separate, with each of these items further segregated into labor and materials. Operation charges should include such items as labor required to clean sewage screens, to attend to the operation of settling tanks, to remove sludge from drying beds electric power used to operate sewage and sludge pumps, chlorine used for treatment purposes, chemicals and supplies. Maintenance charges are embraced in such items as labor and materials needed for repairs, the painting of buildings and the storage of materials and supplies.

It is of particular importance that daily records of the quantity of sewage treated be obtained, together with the approximate number of persons served, so that the cost per million gallons of sewage and the cost per capita per year can be calculated. The general character and strength of the raw sewage should be known, as the cost of treatment is dependent thereupon.

It often becomes difficult to decide whether the cost of certain work should be added to the first cost of the plant, or should be included in the maintenance charges. The circumstances surrounding each case must be known before a satisfactory decision can be made. Let it be assumed, for example, that a pump is purchased for handling sludge. If the plant had never been equipped with such a unit, the installation should be classed as a new improvement, and the cost incorporated in the first cost of the plant; if the pump replaces another unit of the same kind because the latter has worn out, the first cost of the plant remains the same and the cost can be charged to depreciation reserve, but if the above replacement were due to the existing pump being damaged, the cost should be added to the maintenance of the plant.

Cost of Operating the Baltimore Sewage Works.—The cost of operating the Baltimore sewage works from 1921 to 1928 is shown in Tables I and II. Table I gives both the fixed and the operating costs on a million gallon and a per capita basis. It is of interest to note that during this period the fixed costs have fluctuated over a narrow range from a minimum of $0.337 to a maximum of $0.371 per capita per year, a variation of about 10 per cent. The per capita operating costs have fluctuated more widely, from $0.143 to $0.191. The operating costs per capita reached a maximum in 1922, and since then they have been decreasing, due chiefly to a greater number of persons being served.

In Table II the costs have been segregrated under ten different headings. These costs, as well as those given in Table I, do not contain any salaries other than paid to the employees at the sewage works. Thus, general overhead is not included. The cost of superintendence, including the salaries of chemists, clerks, foremen, watchmen, and janitors is distributed over the ten items in Table II.

Since the principal item of expense in operating the plant is labor and supervision, the personnel and their salaries are given in Table III. There is usually little fluctuation in the number of employees except in the number of laborers employed to remove sludge from the drying beds and to maintain the ground drying beds and to maintain the grounds. With reference to the former group as many as three gangs are needed at times, with 10 men in a gang, exclusive of the foreman and the operator who drives the locomotive. During the spring and fall, however, one gang is sufficient. The maintenance of the grounds which consists mostly of cutting shrubbery and grass, frequently requires the services of from two to six men.

The cost data compiled at the Baltimore works have been of great value as a basis of comparison with the cost of other methods of sewage treatment, especially where these methods have been considered for adoption at the Baltimore plant. Similar costs, compiled at other sewage works, should prove useful to engineers and others who are interested in sewage treatment.

Acknowledgment.—The foregoing is taken from the July Sewage Works Journal.

Table III—Personnel of the Baltimore Sewage Works

Title	Number Employed	Salary
Supervising force		
Superintendent	1	$2,800 per year
Chemists	4	$1,600 to $2,500 per year
Clerk	1	$1,600 per year
General operating force		
Foreman	1	85 ct. per hour
Operating engineer	1	$1,800 per year
Sewage sampler	1	50 ct. per hour
Storekeeper	1	50 ct. per hour
Janitors	2	30 ct. and 45 ct. per hour
Watchmen*	2	45 ct. per hour
Laborers	12	45 ct. per hour
General maintenance force		
Machinists	2	75 ct. and 80 ct. per hour
Electrician	1	$1,900 per year
Carpenter	1	70 ct. per hour
Chauffeur	1	50 ct. per hour
Helpers, handymen, etc.	5	45 ct. and 50 ct. per hour
Bar screens		
Laborers*	2	50 ct. per hour
Settling and sludge tanks		
Laborers	10	45 ct. and 50 ct. per hour
Revolving screens and trickling filters		
Operating engineers	4	$1,500 to $1,600 per year
Laborers*	2	45 ct. per hour
Sludge drying beds		
Foreman	1	65 ct. per hour
Locomotive operator	1 to 2	50 ct. per hour
Laborers	10 to 22	45 ct. per hour
Final sludge disposal		
Crane operator	1	55 ct. per hour
Maintenance of grounds		
Laborers	2 to 8	45 ct. per hour
Total	69 to 88	

Note: Supervising force works 39½ hours a week. Remainder of personnel works 48 hours a week except as noted.
The salaries paid during 1928 totaled $89,186.55.
*Work 56 hours a week.

Field Chlorination of New and Old Mains

Practice at Baltimore, Md., in Disinfecting Water Pipe

By J. H. STROHMEYER
Assistant Civil Engineer, Water Department, Baltimore, Md.

IN conformity with advanced standards of sanitation generally prevailing, the Bureau of Water Supply, of Baltimore, has been disinfecting water mains immediately after laying and prior to placing them into service. This procedure, the value of which I was at one time skeptical, has been forced upon us by circumstances which indicate quite conclusively the necessity for such sanitary measures.

Five years ago the matter was brought forcefully to my attention when a main laid by a contractor was flushed and gave forth articles which were anything but conducive to purity. It was evident that the pipe, which had laid for six months along the side of an arterial highway, had received but a cursory inspection before installation. Such a condition demanded definite action and our water main chlorination policy was inaugurated at that time.

Contamination of Pipe in Yards and Field.—A number of bacteriological tests were made to determine the probability and extent of contamination in pipe stored in our yards and of pipe distributed in the field. Cultures made from samples taken from the pipe stored in the yard developed generally negative results in both gas formation and excessive counts.

It is a matter of some interest that the cultures from the pipe piled in a north and south direction were generally better than those from pipe piled in the east and west direction. This may have been the result of the first mentioned pipe being exposed to the ultra violet rays of the north light. Because of the numerous buildings in our pipe storage yard causing eddy currents, I am of the opinion that the prevailing winds could have had little bearing on our observed data. The cultures taken from the pipe distributed along the line of its proposed installation and having been exposed to contamination for varying periods of time were found to be almost uniformly bad.

The results of tests of samples taken later at various times corroborate the first findings and indicate that contamination occurs in the field.

Standard Treatment at Baltimore, Md.—A standard treatment was established, which has been carried out as consistently as possible, providing an application of available chlorine of 100 p.p.m. of water. In terms of weight this ratio is 0.6 lb., or 10 oz., of free chlorine per 100 cu. ft. of main volume to be disinfected.

For small mains from 6 to 10 in. in diameter, calcium hypochlorite is applied by the water pipe construction foreman during installation. Since about 33 per cent chlorine is available in this compound, the amount of lime applied is about 2 lb. per 100 cu. ft. Upon completion of construction the main is charged very slowly and allowed to remain so for 24 hours when it is thoroughly flushed.

Under certain conditions, chemical treatment of this type is not practical. For example, a main which has been open in a trench for some period of time and which has accumulated a deposit of mud or other earthy material, requires, first, mechanical purification in the removal of the material either by scraping, flushing or both. In such cases it is impossible for a normal dose of chlorine and water to penetrate the foreign masses. Since these are most likely to be contaminated, the mechanical cleansing becomes practically a necessity before chlorination.

Cost Is Slight.—Chlorine gas, which is obtainable in tanks of portable size, is easily applicable to water main purification. Modern production methods and the great quantities in which it is now manufactured for the use of water works and other trades make its cost reasonable. Whether used in the form of hypochlorite of lime or as a free gas, there is no question in my mind, but that its slight cost is more than justified in the security following its use. It costs 1 ct. a foot to disinfect a water main with hypochlorite of lime and 2 ct. a foot using chlorine gas.

The method of application is arbitrary and matters little so long as effective mixture with the water is obtained. The free gas lends itself very readily to this mixing and for that reason should be given prime consideration when an extensive program of water main purification is being considered.

Methods at Baltimore.—After some years of experimentation a very efficient method was devised and an experimental injector was designed and built at the Bureau of Water Supply in Baltimore. The injector depended upon pressure of chlorine in the cylinder to force the gas into the main. While it worked quite well on several small jobs, it was found that its capacity was not sufficiently great to allow efficient chlorination of greater volumes. Our latest development consists of a mixing valve, a supply hose, a discharge hose and incidental fittings. In detail, the apparatus is arranged as follows: The syphon connection on the mixing valve is attached by a rubber hose to the chlorine cylinder, the supply hose is connected between a corporation cock in the old section of main and the supply end of the mixing valve, a hand valve being inserted in that point to allow adjustment of the flow, the discharge hose carrying the water and chlorine mixture fastened to the discharge side of the mixing valve and the injector tube. The tube is inserted through a corporation cock into the newly laid main.

The operation of the apparatus is very simple. Both corporation cocks are open, the hand valve is opened slightly to allow a small jet of water to flow through the mixing valve; the chlorine valve is opened, after which the hand valve is opened to the fullest extent, creating a noticeable suction on the chlorine supply. The line valve separating the new and old portions of main is raised the desired amount to produce a turbulent flow through the new section. The degree to which this main valve is opened depends upon the size of the flushing orifice at the end of the new section.

Operations Involved.—This method of chlorinating combines three operations, the latter two of which are valuable to purification. The first of these is the initial charging of the main, the other two are flushing and chlorinating, thus combining mechanical and chemical purification. Since the concentration of chlorine of 100 p.p.m. produces a residual chlorine content quite noticeable by odor, a uniform dosage is applied until such time as in the opinion of the operator it has reached the desired ratio. At this time the main valve and the blow-off are both closed, the chlorine tank disconnected, the hand valve on the supply line closed, the injector withdrawn from the corporation cock, which is then closed, and the apparatus thoroughly washed by means of the supply hose. Despite this washing, it is practically impossible to prevent corrosion of the ¾-in. silver plated injector tube, which has to be replaced at frequent intervals. A new type of injector is now being experimented with, which is resistant to, or rather unaffected by, oxidation, it being a glass tube enclosed in a hard rubber or bakelite casing.

The chlorinated water is allowed to remain 24 hours, after which interval the main is thoroughly flushed and placed into service. For definite assurance that the main is free from chlorine, a sample is taken from the blow-

off and tested for free chlorine by the ortho-tolidin or starch iodide method.

Chlorinating Old Mains.—In chlorinating old water mains, our practice is similar to new main chlorination. A section of the old main is removed in order to determine the amount of tuberculation, the types of microscopic growth, and to observe the general physical condition. From this information it is possible to decide upon a course of action which will enable us to purify along the most efficient lines. Personally, I believe that most old mains should be scraped and cleaned before attempting chlorination. However, we seldom find it necessary to chlorinate an old water main.

Sterilization of water mains is not a possibility, or better, not a practicability because of conditions over which the agents have no control. Purification or disinfection is, however, quite possible, since the purpose thereof is the destruction of bacteria pathogenic to man. The degree of disinfection varies with the amount of oxidation which has taken place, which in turn is indexed by the amount of free residual chlorine. Therefore, contrary to what I feel is a more or less popular belief, free residual chlorine does not indicate a sterile main, but serves rather to indicate a factor of safety, since there is no absolute certainty that the chlorine has penetrated every cubic inch of the treated volume.

Table Showing the Amounts of Hypochlorite of Lime Necessary to Disinfect One 12-Ft. Length of Main

Diameter of main in inches	4	6	8	10	12
Ounces of hypochlorite of lime	0.34	0.75	1.33	2.09	3.01
Tablespoonfuls, hypochlorite of lime	½	1	2	3	4

Odor Control at Sewage Disposal Works

Experiments in 1928 at New Jersey Plant

By JOHN R. DOWNES

Supervising Engineer, The Plainfields and Dunellen, N. J., Joint Sewage Disposal Works

ODORS naturally divide themselves into two classes: local and migrating. Local odors are such as may emanate from exposed sewage solids about screens or where they may have been carelessly dropped by attendants, or grease cakes forming just above the water line of sedimentation tanks and baking in the hot sun. Such odors and those about small pump stations may be annoying close at hand, but certainly would not be noticeable 50 yards from the source.

Cleanliness and the use of a good deodorant such as Phinotas will overcome local odor difficulty, though care should be taken to choose a deodorant which has an odor not worse than that which we seek to overcome. By this I mean that a good honest ammoniacal, stale urine odor is much preferable to many of the compounds used about public toilets. However, some very pleasing effects may be secured by carefully selecting the proper compounds.

By migrating odors, I mean odors that travel more than 100 yards, and this may stretch to a mile or two under favorable conditions. This type of odor is occasionally carried by high winds, but is then dispersed, within a reasonably short distance, by the very wind that carries it. They become really troublesome under the peculiar atmospheric conditions which produce smoke flags. These conditions most often occur about dusk.

Smoke Flags.—Probably all have noted times when a trail of smoke from a bonfire will hang suspended in the air a definite distance from the ground and from any object which it approaches. The smoke does actually travel in a definite direction, but so slowly that its movement is not visible. Also, which is the crux of the situation, so slowly that it is not broken up by eddies, or dispersed on approaching an object in its path, but flows, ever so gently, around or over such object. Usually, if you observe these smoke flags, you will see that they do not actually touch objects in their path but pass around them at a definite distance. It is this condition which makes shrubbery screens useless as odor controls. When there is wind enough to give obvious movement to the air currents, the odor cloud is broken up by impingement against the shrubbery wall, but without such degree of velocity the screen is ineffective, since the analogous smoke flag is often observed to trail over an intervening forest and descend unbroken on the opposite side.

The chief offending compounds which migrate in this fashion from sewage disposal plants are hydrogen sulphide and its allies. It has been definitely shown that this gas is attacked by chlorine with the formation of substitution products with odors varying from "Medicated" (chloroform) to zero, according to the quantity of chlorine used.

Cost of Odor Control.—While the quantity of chlorine used for this treatment appears large when figured in parts per million, Lynn Enslow and Wm. J. O'Connell, Jr., have developed the idea that the peak of hydrogen sulphide production is almost always coincident with the afternoon peak of sewage flow and it is only necessary to apply chlorine on this peak and possibly during the early evening hours, when there is still some of the offensive gas being carried over from the settling tanks, and when atmospheric conditions are ideal for the formation of smoke flags.

For instance, at the Plainfield plant the rate of use of chlorine is 400 lbs. per day, but it is necessary to apply it only during four or five hours with a total daily consumption of 70 lbs. Under these conditions, and with chlorine procurable at 6c per pound the cost for odor control during six summer months approximates $700.

We treat only during the summer months because hydrogen sulphide is produced in troublesome quantities only during warm weather.

Odor Control by Partial Activation.—Treating 25 per cent of the settling tank effluent by the activated sludge process and then mixing this treated portion with the balance of the tank effluent, very effectively destroys the hydrogen sulphide odor. From the operator's point of view, this method is preferable to chlorine treatment, but even though we can secure our power free by making use of the gas from the digestion tanks, the carrying charges on the machinery installation for the activated sludge process, are greater than the cost of chlorine plus the carrying charges on the chlorine feed apparatus.

Age of Sewage and Temperature.—Whether we have simply local odors amenable to deodorants of the Phinotas type, or migrating odors requiring chlorine or activated sludge treatment, will depend largely upon the age of the sewage and its temperature. For time is a factor in the production of the troublesome hydrogen sulphide, the time necessary for its production in disturbing quantities being shortened as the temperature rises. Even though the sewage reaches the plant in a fairly fresh condition, hydrogen sulphide in odor producing volumes may develop in the settling tanks where these are larger than the minimum required for sedimentation.

Odors from Digesting Sludge.—Uncontrolled digestion of sludge with exposed surface is a prolific source of odor. However, with our present knowledge of optimum digestion conditions, there is little excuse for odors from this source. The floating covers used at the Plainfield plant effectively eliminate odors from this source by (a) preventing exposure to the atmosphere, (b) keeping all floating material submerged, in which case certain odoriferous compounds, otherwise formed, are not produced, (c) providing a perfectly safe means of collecting the gas generated, thus making it available for heating the digesting sludge to the optimum temperature.

Storage-Discharge Method of Sewer Design

Takes Advantage of the Full Value of the Storage Factor

By WM. R. MATHEWS
Engineer of Sewers, Bureau of Sewers, Chicago, Ill.

WHEN a system of sewers is designed by the rational formula the branches and upper part of the system have higher capabilities per acre than the lower parts, so that they flow but partly full during the rainfalls that fill the lower sections. If the lower sections be undersized the flow is restricted and the upper sections and branches fill. If there be sufficient storage in these parts of the system the entire system may prove adequate.

Sewers may be designed so that advantage may be taken of the full value of the storage factor by the application of what I will call the "storage-discharge" method, which may or may not be new. The computations necessary to apply the method are tedious, but by applying it to typical cases and comparing the results obtained with those by the use of the rational formula, sufficient data may be had for the modification of the rational equation, which may then be generally applied.

Basis of the Method.—What I have called the "storage-discharge" method of design is based on the proposition that during the time of concentration the total quantity of water entering a sewer system is equal to the quantity stored in it plus the quantity discharged at the mouth. Values may be given to this entering quantity, to the quantity stored, and the quantity discharged, and an equation may be written and solved to give the sizes of a sewer section by section, beginning at the upper end and working toward the outfall.

The first term of the equation is the quantity entering the sewer. This quantity is the product of the co-efficient C, of the intensity of rainfall I, of the area drained A, and of the time T'. The time T' is the time concentration less one half of the inlet time, it being assumed that, during the inlet time, the entering rate increases uniformly from zero to the full rate I. The entering quantity may be written $C\,I\,A\,T'$.

The second term of the equation is the storage. For the first section of the sewer it is the product of the length of the sewer and its cross-sectional area. For the second section of the sewer it is the product of the length and the cross-sectional area plus the storage in the first section. For the third and following sections it is obtained in the same manner.

The third term of the equation is the quantity discharged from the sewer. When the area drained is a rectangular one, with the sewer parallel with one edge, the quantity reaching the mouth of the sewer product $C\,I\,A$ and the discharge is therefore the product of the mean discharge and the time of concentration, or one half of $C\,I\,A\,T$. If the size of the sewer be reduced to take advantage of the storage the rate of discharge will increase uniformly as before until it reaches the full capacity of the sewer, and the sewer will then flow full for the remainder of the time of concentration.

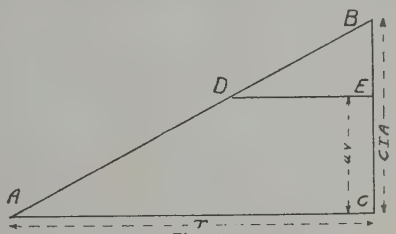

Fig. 1

The discharge of the sewer if reduced is shown by Fig. 1.

The base of the triangle ABC is the time of concentration T, the side BC is the product $C\,I\,A$, which is the rate of flow at the end of the time of concentration, and the area of the triangle, one half of $C\,I\,A\,T$, is the discharge at the mouth if the flow is not restricted. If the flow be restricted to take advantage of the storage the rate of discharge at the end of the time of concentration is represented by the line EC which is equal to av, the product of the cross-sectional area of the sewer and the velocity. The vertical ordinates of the line AD—DE represent the rates of flow during the time of concentration, and the area of the figure $ADEC$ the total discharge at the mouth. By similar triangles this area equals

$$T\left(av - \frac{a^2v^2}{2\,CIA}\right).$$

The equation for the design of a sewer by the storage-discharge method may now be written:

$$C\,I\,A\,T' = S + T\left(av - \frac{a^2v^2}{2\,CIA}\right)$$ in which

C = percentage of water reaching sewer.
I = intensity of rainfall.
A = area drained in acres.
or sewers.
S = storage, the cubical contents of sewer.
T = time of concentration in seconds.
a = cross-sectional area of sewer.
v = velocity.

Application of Methods.—I have applied this method to a district one-half mile wide containing 640 acres, with the sewer running lengthwise through the middle, with branches in two directions every 330 feet, each branch draining ten acres, using the following values:

$C = 25\%$.

$I = \frac{104}{t + 17}$ (t = time of concentration in minutes).

T = time of concentration in seconds = length of sewer divided by velocity plus inlet time.

Inlet time = 5½ minutes.

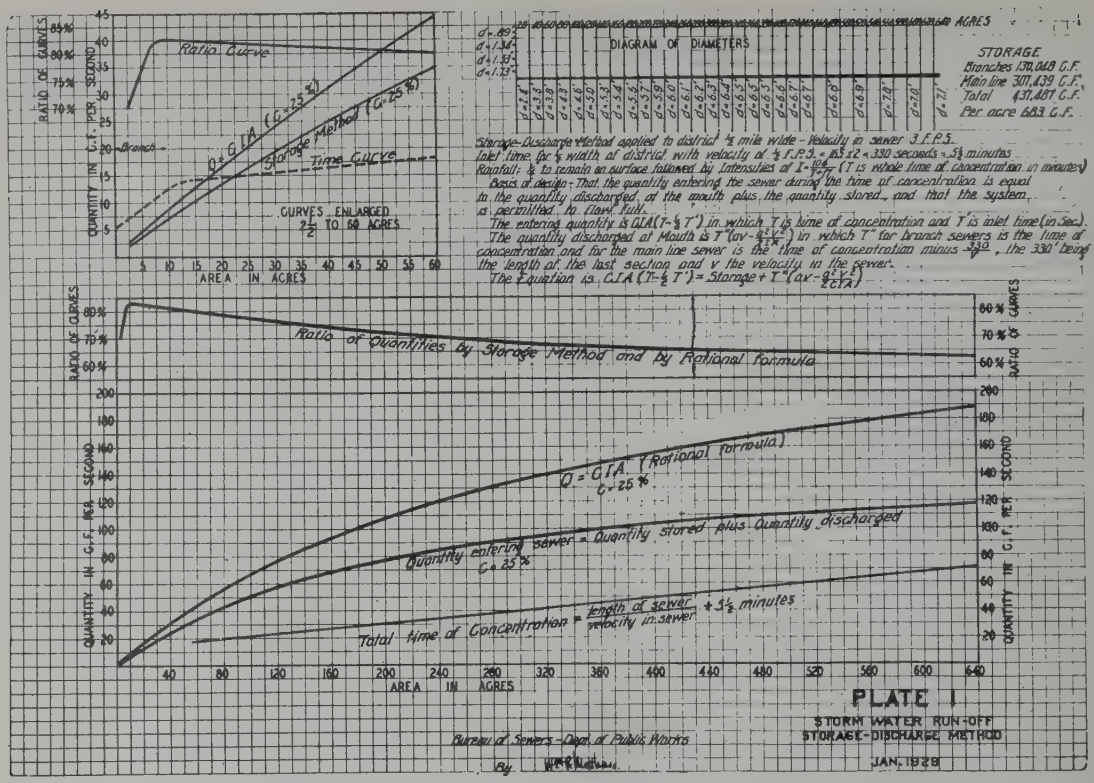
V = velocity in sewer, 3 feet per second.

For the branches the discharge is $T\left(av - \frac{a^2v^2}{2\,CIA}\right)$, as given before. For the main sewer this was slightly modified, T being reduced to $T - \frac{330}{3}$, it being assumed that water entered the main only by way of the branches, so that there was no discharge at the down-stream end of each section of the main for the first 110 seconds.

The method was first applied to the terminal section of a branch sewer draining 2½ acres, then in turn to 5, 7½, and 10 acres; then to the first section of the main, draining 20 acres, and so on to the last section of the main draining 640 acres. The results have been compared with those obtained by the application of the rational formula and are shown on the curve Fig. 2. This shows curves for the values of Q for from 0 to 640 acres as computed by the rational formula and as computed by the "storage-discharge" method. A curve is also given which gives the ratio of the values obtained by the two methods.

Comparison with Rational Formula.—It will be noted that the size (cross-sectional area) of a sewer for 20 acres by the storage-discharge method is 83 per cent of the size by the rational formula and that for 640 acres the size is but about 63 per cent, the ratio of sizes decreasing with the increase of the acres. The curves shown do not extend beyond 640 acres, but some preliminary computations on a rectangular area one mile wide indicate that a sewer to drain about 2,000 acres designed by the storage-discharge method would be but about one-half the size of one designed by the rational formula.

The values of C which I have sug-



Ratio Curve

CURVES ENLARGED 2½ TO 60 ACRES
RATIO OF CURVES
QUANTITY IN C.F. PER SECOND
AREA IN ACRES
DIAGRAM OF DIAMETERS
STORAGE
Branches 130,048 C.F.
Main line 307,439 C.F.
Total 437,487 C.F.
Per acre 683 C.F.
Storage-Discharge Method applied to district ½ mile wide - Velocity in sewer 3 F.P.S.
Inlet time for ½ width of district with velocity of ½ F.P.S. = 165 x 2 = 330 seconds = 5½ minutes
Rainfall: ½ to remain on surface followed by Intensities of I = 100/(T+10) (T is whole time of concentration in minutes)
Basis of design - That the quantity entering the sewer during the time of concentration is equal to the quantity discharged at the mouth plus the quantity stored, and that the system is permitted to flow full.
The entering quantity is CIA(T-½T') in which T is time of concentration and T' is inlet time (in Sec.).
The quantity discharged at Mouth is T(av - g²v²/2CIA) in which T for branch sewers is the time of concentration and for the main line sewer is the time of concentration minus 330/v, the 330' being the length of the last section and v the velocity in the sewer.
The Equation is C.I.A (T-½T') = Storage + T'(av - g²v²/2CIA)
Ratio of Quantities by Storage Method and by Rational Formula
Q = CIA (Rational formula) C = 25%
Quantity entering sewer = Quantity stored plus Quantity discharged C = 25%
Total time of Concentration = Length of sewer / velocity in sewer + 5½ minutes

gested for use in the rational formula of from 35 per cent to 45 per cent for "well built-up" areas and 60 per cent for areas approximately 100 per cent impervious are roughly equivalent to values of C in the storage-discharge formula of from 55 per cent to 65 per cent for "well built-up" areas and 85 per cent for areas approximately 100 per cent impervious. These latter values for C seem the more reasonable.

Uses of Reclaimed Sewage at Grand Canyon

In an article on "Activated Sludge Practice in the United States" in our September issue, it was stated in the last paragraph on page 366, that "Chlorination of the effluent is carried out at Lodi, Pomona, Pasadena and Grand Canyon, in the first three instances to protect irrigated land from any germs of disease that might survive and at Grand Canyon for the drinking purposes in place of the restricted water supply."

This statement regarding the uses of effluent at the Grand Canyon was, of course, erroneous. As a matter of fact the reclaimed sewage at the Grand Canyon is used for industrial purposes only and every conceivable precaution has been taken to prevent any cross connection between the drinking water and reclaimed sewage water supply systems. A competent chemist is in charge of the treatment plant and frequent tests are made day and night to make sure that the reclaimed sewage is sterile at all times.

The following extract from a paper, "Sewage Treatment Plant at the Grand Canyon National Park," by H. B. Hommon, Sanitary Engineer, U. S. Public Health Service, the designer of the plant, brings out clearly the uses of the reclaimed sewage and the precautions that have been taken; it also gives some interesting information on the cost of operation:

Uses of Reclaimed Sewage.—At the present time the reclaimed sewage is used in stationary boilers for generating steam for heating purposes, and in the locomotives that haul passengers and freight trains on the branch line of the Santa Fe from Williams to the canyon; for cooling water for Diesel engines; for irrigating lawns around the hotel; and for flushing toilets in the public comfort stations in the El Tovar Hotel, Bright Angel Camp, railroad depot, and the Government automobile camp.

The force main from the treatment plant runs direct to the storage tank with only one branch taken off to supply cooling water for the Diesel engines. The entire distribution system from the storage tank is inclosed in vitrified pipes up to the outlets or fixtures where the reclaimed sewage is used. Beyond the vitrified pipe the uncovered distribution lines are painted red. The sewer pipe will prevent cross connections to fresh water lines. The pressure on the fresh water mains is greater than that on the reclaimed sewage lines. No valves, spicots, or any other openings are permitted on reclaimed sewage lines except where absolutely necessary. Accurate maps are kept up to date showing all the fresh water and reclaimed sewage pipe lines and no extensions or alterations of either piping system can be made without the approval of the superintendent of the park. With these limitations and precautions in distributing the reclaimed sewage, and the careful supervision given to the operation of the treatment plant, it is believed that it will be possible to use the reclaimed sewage indefinitely without any danger to the health of visitors to the park or of employees.

There has been no criticism by employees at the canyon who use the reclaimed sewage for generating steam or for any other purposes. The locomotive engineers vigorously opposed the use of "sewage" in passenger engines at first, but after a demonstration by an expert engineer they used the reclaimed sewage and found that it produced less scale than the fresh water obtained at the canyon.

All the reclaimed sewage is now being used for the purposes named above, and no others will be permitted, except possibly the washing of automobiles, under certain restrictions.

The treatment plant is operated under the supervision of a competent sanitary engineer who has two trained assistants.

Cost of Operation.—In considering the cost of operation, the fact should be kept in mind that the plant was designed and is operated to produce an effluent of the same degree of purity from a bacteriological standpoint as drinking water, and that every 1,000 gallons of reclaimed sewage that can be used in place of fresh water is worth $3.09. The cost data, therefore, should be considered in relation to water filtration rather than sewage disposal.

The average volume of sewage reclaimed daily during 1927 was 79,000 gal., and the itemized cost of treatment per 1,000 gal., was approximately as follows:

Electric current at 5 ct. per kilowatt:	
Operating blower	$0.20
Returning wash water	.003
Operating clarifier	.01
Lighting	.003
Labor for operating plant:	
2 operators and sanitary engineer	.177
Liquid chlorine, oil, grease, repairs to equipment, and extra labor	.009
Interest on investment (treatment plant only)	.086
Depreciation (treatment plant only)	.086
	.574

These costs would be reduced approximately one-half if the plant were operating at the capacity for which it was designed and if electric current were available at the commercial rate charged in cities; and the labor cost would decrease materially for plants treating large volumes of sewage.

Five Important Weather and Earthquake Cycles

Clay Varve and Tree Growth Records Employed With Electromagnetic Whirl Hypothesis

By HALBERT P. GILLETTE

A STUDY of annual tree-ring growth and of the annual clay laminae ("varves") deposited in ancient glacial lakes discloses five important weather cycles. For reasons given in "Municipal News and Water Works," and in "Engineering and Contracting," October, 1928, I have assigned these cycles to planets whose magnetic fields cause many sunspots when their north magnetic poles are pointed most directly at the sun. The magnetic fields of the sunspots, in turn, cause cyclonic storms on the earth, probably by producing a greater concentration of free electrons, or perhaps by releasing electrons from the atoms. The magnetic fields of the earth cause the free electrons in the air to rotate, thus producing both cyclonic storms and most of the general air currents that have hitherto been regarded as convection currents. Similarly electromagnetic whirls are caused in the molten interior of the earth.

The following are the lengths of five very important weather cycles, and dates of the last maxima:

Cycle Due to	Length of Cycle, Yr.	Last Maximum
Jupiter	11.214	1928.8
Uranus	81.15	1870.5
Neptune	161.4	1778.4
Planet A	322.4	1675.0
Planet E	3300	440 B. C.

In the article above referred to, I assigned the sunspot maximum of 1778 to Planet A (an unseen but clearly evident planet), but a more extended study of the radial growth of California giant redwoods and of clay varves has shown that Neptune caused that peak; and that the spot peak of 1675 was due to Planet A and not to Neptune.

Neptune's next sunspot peak will occur in 1939 at about the time that a Jupiter peak is due; and the next peak of Uranus will occur in 1951, also about the time of a Jupiter peak. In short, the conditions of 1778 and 1789 will soon be repeated, but with the added effect of Jupiter. Since the period of 1778-89 was one of unusual cold and precipitation, it is to be expected that the period of 1940-51 will be about the same. However, as will be shown in a later article, there is another factor that will tend somewhat to reduce the rainfall during 1940-51; but the 11-yr. period, 1951-1962, will be correspondingly wetter. Indeed this last-named period will probably be the coldest and wettest that has been experienced in North America since the 1778-89 period. This does not mean that all the years of these 11-yr. periods will be very wet, but only that the average wetness will be abnormal.

We have just passed through a relatively dry period of 22 years, and are now entering upon a relatively wet period of 33 years, because we are approaching sunspot peaks due to Neptune and Uranus, which have never failed to produce marked increases in the radial growth of the California and Arizona trees. The Arizona pines are particularly good recorders of rainfall, for they grow in relatively dry areas. Prof. Douglass has carefully measured their growth, and his charts and curves tell the rainfall story for every year back to 1395.

The clay varve measurements of Baron Gerard De Geer and of his one-time pupil, Prof. Ernst Antev, constitute an invaluable record of precipitation running back 18,000 years. The California redwoods give rainfall records for about 3,000 years. These varves and tree-ring records have been the main sources of information by which I have checked my theory as to the weather cycles caused by the planets named above. However, without a theory to guide me I doubt whether I should have found these cycles at all, except, of course, the well known cycle of 11.2 years. The other four cycles have far more important weather effects than that of Jupiter, but coming less frequently they have not been recognized as being regular cycles of the lengths above given.

The 3,000-year cycle is one of the most interesting, for it produces profound effects. The very cold and wet period that prevailed for a long time around 440 B. C. was followed by an exceedingly arid period for many years, centering about 1200 A. D., which was finally relieved by a wet cycle caused by Planet A, culminating in the very wet and stormy years of the 14th century, when planets A, Uranus and Neptune produced very severe weather.

There are three names that I venture to predict will ultimately stand very high in the history of meteorology, yet not one of the three is the name of a professional meterologist. I refer to Professors De Geer, Douglass and Huntington, named in the order of the dates of their first publications relating to weather cycles. Professor De Geer, the great Swedish geologist, began his study of annual clay varves more than 50 years ago, and soon found a periodic variation of about 11 years. Professor Douglass, an astronomer, began his study of tree-rings in 1904 and also soon found the 11-yr. cycle, together with an intermediate cycle of about 5 or 6 years. Professor Huntington, a geographer, at about the same time began publishing the results of his studies showing historic cycles of climatic changes. Then he followed this up with his measurements indicating a grand cycle in the growth of California redwoods, culminating about the fifth century before Christ, but he did not deduce the length of that cycle. He also found the 11-yr. cycle in the growth of these giant trees. Professor Douglass then made a more detailed study of California redwood growth, confirming Professor Huntington's general conclusions.

In spite of the clear evidence given by this remarkable pioneer work of De Geer, Douglass and Huntington, meteorologists have practically ignored it, and have not followed it up with any independent investigations of consequence. Hydraulic engineers, who are appliers of science rather than researchers, have not used the clay-varve and tree-ring data, because there was an evident complexity that made the data of little practical utility.

About three years ago, I began a determined attack upon this problem, with results that are already very satisfactory. I have found the cause of sunspots, and I have found a sunspot cycle due to every one of the eight visible planets, and to several planets as yet unseen but knowable by their effects on tree-growth; clay-varve thickness and the periodicity of geological epochs, periods and eras. (See the article above mentioned.) If skepticism arises as to any such knowledge about unseen planets, it should be remembered that no one has yet seen a molecule, to say nothing of an atom or an electron. Yet we confidently act upon atomic and electric theories—based upon the existence of those invisible units of matter. It will not be long, I think, before weather forecasters will take into consideration the effects of invisible planets, notably Planet A, the planet whose existence Lowell and Flammarion have independently predicted from astronomical considerations. I am now confident that it caused the sunspot maximum of 1675. There is a marked bulge about 1675 in the curve of tree growth of Arizona pines, and a series of such bulges prior thereto, about 322 years apart, on the curve of California redwood growth that I have plotted from the tables given by Professor Douglass. This latter curve extends from 1220 B. C. to 1914 A. D., giving the thickness of wood added each year.

In this connection it may be well to speak of the significance of the tree-growth maxima that occur about midway between the Jupiter sunspot peaks, that is, at sunspot valleys or minima. Douglass is the first to have mentioned this phenomenon; but he offered no explanation of it. At first it seemed to me likely that it is due to the periodic shifting of storm tracks, according to Kulmer's law; but more mature reflection showed that this could not explain the phenomenon.

According to the electron-whirl theory of sunspot and weather cycles, free electrons migrate on the earth under the influence of the magnetic fields of the sun, sunspots and planets. This migration changes the density of the free electrons in the atmosphere and in the earth, and results in changes in the intensity of the 12 permanent cyclonic whirls and of the numberless migrating cyclonic whirls. While sunspots, because of their magnetic fields, are important factors in causing such migrations of electrons, the magnetic fields of certain planets are much more important. Thus, when either one of Jupiter's magnetic poles is most inclined toward the earth, many cyclonic storms are generated on the earth. The same holds true of Uranus, Neptune and Planet A.

Incidentally this migration of electrons explains the existence of the flow of electrons from the earth to the air above it; for electrons migrate from the Heaviside layer (75 miles above the earth) downward toward the poles and thence through the earth toward the equator. In short, streams of rotating belts of electrons are maintained by magnetic pressure. The same sort of phenomenon occurs on the sun, and accounts for sunspots and for their periodicities.

Accordingly I adopted the hypothesis that although Jupiter's magnetic field produces few sunspots when its north magnetic pole points sunward, it does produce a concentration of free electrons in the earth's lower air and molten matter, so that both air-whirls and molten-whirls of greater frequency, intensity and size result. In short, Jupiter acts directly upon the earth when its north magnetic pole points earthward. Probably it also acts directly on the earth when its south magnetic pole points earthward, but this effect is so commingled with the effect of the sunspots that are then generated in great numbers as to make it difficult to determine the direct action of Jupiter.

No sooner had I reached this conclusion than I saw that there is a weather cycle of about 5.6 years (½ of 11.2) which intermediate rainy periods from a Jupiter peak is due to its north pole. These cycles are not precise as to time, there being a small swing on each side of the mean, because the earth travels in an orbit, cutting across the magnetic field of Jupiter twice each year. Jupiter is moving orbitally eastward and its magnetic poles are slowly rotating westward, which introduces some complexity, but a complexity that is rendered relatively simple when studied in the light of the facts just given.

In a chart of annual earthquake intensity, given by Edward Lynch in his "Solar Physics and Earthquakes," I find clear evidence not only of the 11.21-yr. cycle of Jupiter, but of the half period above mentioned. Huntington has commented upon the general tendency of rainfall maxima and earthquake maxima to concur, and this adds another bit of evidence in support of that theory. Huntington attributes such concurrence to the great changes in air pressure on the earth during stormy periods, whereas I attribute it to the molten-whirls in the earth that are electromagnetically generated by the same causes that generate the air-whirls.

The Encyclopedia Americana, under Disasters, cites 28 disastrous earthquakes and 38 great plagues and pestilences that have afflicted the world since the birth of Christ. I have listed all of these in the footnotes of Table I. Study discloses that great earthquakes have frequently occurred near the time of a Uranus maximum, and not infrequently near the time of a Uranus minimum magnetic effect. The same holds true of plagues. Since the latter are often caused by bacteria that are the hosts of mosquitoes, and since mosquitoes are more prevalent during rainy periods, there is a reason for the cycles of certain plagues. Perhaps all bacteria thrive best during rainy periods.

Of the 28 disastrous quakes, 13 occurred within 9 years of a Uranus maximum (Table I). Since the Uranus cycle is about 81 years, the probability that this would occur by chance is 1 in 3,594; for $2 \times 9 = 18$ years and $81 \div 18 = 4.5$; whence the probability of a single occurrence is 1 in 4.5. But there are 13 occurrences out of 28, whence by applying formula 23 given in "Probability and Its Engineering Uses," by T. C. Fry, we get a probability of 1 in 3,594.

By way of explanation, there is a probability that this event could occur 28 times out of 28 possibilities. The measure of this probability would be

$$\frac{1}{4.5^{28}} = \frac{1}{1{,}995{,}100{,}000{,}000{,}000},$$ which

is quite small. That is, this fraction measures the probability that the event would occur every time it had the chance, considering the occurrence as fortuitous rather than as demanded by physical law. If there were 28 opportunities for the quakes to occur, the chance of 28 occurrences would be measured by the fraction above.

According to hypothesis there were 28 chances for quakes to occur. According to fact there were 13 occurrences. The hypothesis states that conditions were such as to expect quakes.

If 28 quakes are expected to occur according to physical theory, and 28 occurrences are recorded, then we are likely to assume that $\frac{28}{28} = \frac{1}{1}$, and hence it is a certainly that these conditions absolutely cause quakes. But this reasoning is not quite true, because there is the possibility, as shown by the fraction, that the quakes could occur accidentally coincident with the theoretical or hypothetical favorable conditions.

So far as physical law and probability are concerned there is a difference in status if a quake occurs accidentally or if it is expected. Conditions could be favorable, according to physical theory, for the occurrence of a quake, yet the quake could occur accidentally while those conditions prevailed. The fraction, $\frac{1}{3594}$, measures the probability of getting 13 occurrences accidentally.

It is noteworthy that Jupiter assisted Uranus in producing many of the disastrous quakes. A Jupiter maximum occurred within a year of 10 of the 28 quakes. Hence $11.2 \div 2 = 5.6$; whence the probability of a single occurrence is 1 in 5.6; and the probability of 10 out of 28 is 1 in 80.

The two probability ratios thus deduced are much smaller than the actual probability ratio, for I have taken the extreme departure of an earthquake from the peak effect of each planet; and have made no allowance for the fact that many quakes occur near the time when a planet's south magnetic pole points most nearly sunward, which is at a sunspot minimum.

Huntington and Vischer, in "Climatic Changes," have conclusively demonstrated that earthquakes are most numerous at times of sunspot maxima; but this does not conflict with my inference that they are also abnormally numerous at times of sunspot minima.

The San Francisco quake of 1906 came a few days after an unusual eruption of Vesuvius and almost at the time of a Jupiter maximum effect, and 4 years before a Uranus minimum effect. San Francisco suffered from a severe quake in 1868, two years before a Uranus maximum, and near the time of a Jupiter minimum. A much greater shock occurred in 1872, at the time of a Jupiter maximum, in Owens River valley, about 200 miles east of San Francisco. None of the California quakes have been severe. The quake of 1906 did little damage in San Francisco. The damage was caused by the fire that followed it, as a result of the breaking of water mains. The quakes have their origin along certain well defined faults—where slippage occurs—as a result of the ascending molten-

1917	1917			

Note: A=Planet A; N=Neptune; U=Uranus. The last three columns are given by Fritz.

whirls which behave like ascending cyclonic air-whirls.

Table II gives the dates that I have assigned to the maximum sunspot effect due to Jupiter, and in the next column are the dates that Wolf assigned to sunspot maxima; then follow dates of maxima assigned by Prof. H. Fritz (see "Monthly Weather Review," October, 1928, for a translation of his remarkable article published in 1893) to aurora, wine harvests and hail-storms. His dates of auroral maxima do not always agree exactly with those in the Encyclopedia Britannica, under Aurora, but the differences are immaterial for present purposes. Note the remarkable concurrence of the dates of maxima in the five columns of Table II, bearing in mind that 6 of the 28 sunspot peaks are due to the planets Uranus, Neptune and A, as per Table I. The 22 remaining sunspot maxima find agreement, within a year, in 15 instances.

Since any single instance of such agreement would occur by accident only once in 5.6 times, the occurrence of 15 out of 22 such agreements would be accidental only once in 3,881,455 times, according to the probability formula above cited. This alone would serve to establish the substantial correctness of the Jupiter spot cycle of 11.214 years, but I have established with vastly greater conclusiveness by tracing it back more than 3,000 years in the California redwood rings and 16,000 years back in the clay varves. By aid of the Jupiter, Uranus, Neptune and Planet A cycles, I find that the zero year on Professor DeGeer's chart is 6,764 B. C., and the year 3,000 on Professor Antev's varve chart is 12,449 B. C.; and the zero year on Reed's varve chart is 12,651 B. C. Professor De Geer had previously correlated Reed's American varves and some of Antev's American and Canadian varves with his (De Geer's) Swedish varves, and had expressed the hope that his varve dates would eventually be correlated with the dates of the rings of the California redwoods. He had estimated that his zero year was 6,800 B. C., and I find his estimate to be only 36 years away from the truth.

Professor De Geer has accomplished one of the most remarkable feats in the history of geology, for he has precisely correlated events of the last glacial epoch in Europe, America, Iceland, Argentine and India, by means of clay varves. He has shown fully 80 per cent agreement as to annual changes in thickness of varves. Since the chance is 1 in 2 that two sets of varves will agree by accident, it follows that if 15 successive agreements occur (and this happens very frequently) there is only 1 chance in 2 raised to the 15th power, or 1 in about 36,000, that such a concurrence is accidental. Occasionally 30 or more successive concurrences are to be seen on De Geer's charts, which could not occur by accident once in a billion times. The evidence is thus seen to be overwhelming that De Geer has effected a coordination of the clay varves in five areas that are widely separated; and this, I maintain, is one of the most remarkable achievements in the history of geology. I believe that it is also destined to have a profound effect, not only on meteorology, but on astronomy. For more than half a century this remarkable man has been making and gathering clay-varve measurements; but not until four years ago did he succeed in thus tying together the ice-age chronology of Europe and America. Even yet his great achievement is known by comparatively few scientists, and scarcely at all by the public. Such is too often the slow coming of merited fame.

Automatic Chlorination

Results of a Year's Experience at Concord, N. H.

By PERCY SANDERS
Superintendent of Water Works, Concord, N. H.

ON account of the source of supply being a surface supply and therefore liable to to possible contamination, the water board was advised by Metcalf & Eddy, consulting engineers, the New Hampshire State Board of Health concurring, to chlorinate the water. It was voted by our water board to carry out these recommendations and Metcalf & Eddy were authorized to submit a plan for the installation of a chlorinating plant. Owing to the good record which the water has shown in the way of sanitary and chemical analyses during the 57 years that it has been in use, it was decided that a comparatively minimum in amount of chlorine should be used.

The flow varied from 500,000 gal. to 6,250,000 gal. per day. An automatic type machine was recommended and installed in the fall of 1928 and has now been in operation practically a year.

The machine was furnished by Wallace & Tiernan Co., Inc., and is their Type ASVM automatic control vacuum feed chlorinator with an Ortho-Tolodin testing outfit.

Before the type of machine was decided upon, tests were made of the range of the differential heads on the Venturi and it was found that they varied from .4 ft. to 5.82 ft., or a ratio of 1 to 14.5.

The equipment is placed in the gate house, a small room having been built for it, and the water is chlorinated after passing through the screens.

Rate of Application.—Four meter tubes were furnished which permit the chlorine to be applied at the rate of 30 lb. per 24 hours; 24 lb. per 24 hours; 17 lb. per 24 hours; and 15 lb. per 24 hours, respectively. When we first started the machine we used the 17-lb. tube, which gave a dose of 2.8 lb. per million gallons; later we changed to the 15-lb. tube, which gives a dose of 2.5 lb. per million gallons, or .33 part per million.

The pressure on the line used to carry the chlorine into the water is 33 lb. and the amount of water used to operate the machine in 24 hours is 6,000 gal., or approximately 2,200 gal. for each million gallons chlorinated.

The Ortho-Tolodin test is made a short distance below the Venturi meter at intervals to ascertain if any residual or free chlorine is present, and while we always get a residual at this location, in making the same test at the pumping station we get none at all, showing that all chlorine has been absorbed.

How Chlorinator is Operated.—The chlorinator is operated by the throat and inlet pressures from the Venturi meter located 66 ft. from the machine, which differential pressure is transmitted 22 ft. to a differential convertor. The convertor changes the differential pressure to a vacuum which operates the chlorinator, the convertor being 44 ft. from the chlorinator and 22 ft. below it in elevation.

The operation of the machine was put under the charge of one of our permanent men who was carefully drilled in the care of it by Mr. Hart of Wallace & Tiernan Co., Inc.

The machine is visited four days a week to weigh the chlorine and check it up.

In the winter months we have a little difficulty in keeping the chlorine, chlorine tank and the room itself in an even temperature. Heat is supplied by an ordinary oil heater with reservoir connected by a small pipe to a 10-gal. tank, the flow line of which is at same level as the burner.

The vacuum line leading from the differential convertor to the machine has to be closely watched and drained as condensation will collect and prevent chlorination.

A small bottle of ammonia is kept to detect leaks in the equipment and a gas mask is kept just inside the main door of the gate house for emergency use in case of bad leaks.

We purchase the liquid chlorine from Brown & Co. of Berlin, N. H., who manufacture and use great quantities of it in connection with their bleaching processes.

The machine was in operation for several months before the fact was made public and during that time no complaints were received at the office of any unusual taste or odor in the water.

However afterwards, the case was different for a while; discoloration was noted on glassware, one or two persons had boils which they thought could be attributed to the chlorine and many people thought that the water had tasted queer for some time but hadn't known what the trouble was; we even had communication by mail assuring us that some had detected the change in the water several weeks before.

Everything is quiet now; we are chlorinating regularly and continually and no one notices the difference in the ordinary course of events; occasionally some solitary consumer will return from a vacation and inquire if the water from pipes unused for a month or two tastes and smells queer from the chlorine, but these complaints seem to be the only reminder of the change. There has been no marked improvement in the health of our citizens, but we rest secure that we are doing our best to give our community a clear and sterile water.

Acknowledgment.—The above is an abstract of a paper presented Sept. 18 at 48th annual convention of the New England Water Works Association.

Court Decisions on Sanitary Matters

Recent Rulings of Supreme Courts of Various States

Discharge of Sewage by Borough in Manner to Overflow Land Enjoined.—(Pennsylvania Supreme Court; Freedman et al. v. Borough of West Hazleton, 146 A. 564; decided May 13, 1929.) The borough of West Hazleton discharged sewage, at a certain place in the borough, into an open ditch. This ditch extended over plaintiffs' land to a creek. The polluted fluid spread, at various points along the ditch, over the land of plaintiffs and caused the emission of offensive odors which created inconvenience and unhealthful conditions to families living along the ditch within the borough. In an injunction suit brought by the plaintiffs, whose land consisted of plotted building lots which were suitable and available for residential purposes, the trial court found the above facts. It was also proved that the sewer system, at the point where the sewage entered the ditch, was wholly inadequate and insufficient to prevent the discharge of the polluted waters upon the plaintiffs' property. The trial court concluded that there was a public and continuing nuisance and granted the relief prayed for by the plaintiffs. On appeal by the defendant borough, the supreme court affirmed the lower court's decree, saying that "The facts in this case and the law applicable to them fully support the findings and final decree of the court below."

Regarding the claim, put forth by the borough, that it had a prescriptive right to the use of the ditch over plaintiffs' land, it was held by the supreme court that such claim had no application. The court stated that, although the ditch had been openly used for that purpose since 1902, that fact constituted no defense to a proceeding by an individual for the removal of an unlawful nuisance which developed in later years from such use, and that "the right to maintain a public nuisance can not be acquired by prescription."—Public Health Reports, Aug. 16, 1929.

Provisions of Ordinance Concerning Removal of Garbage Upheld.—(Oregon Supreme Court; Spencer et al. v. City of Medford et al., 276 P. 1114; decided April 23, 1929.) The city of Medford, by ordinance, declared it to be unlawful and punishable by fine or imprisonment for any person, firm, or corporation, other than a certain named corporation, to collect, gather, or haul over the streets of the city any garbage. The plaintiffs, in a suit to restrain the enforcement of the said ordinance, alleged that they were under contract with certain hotels, cafes, and restaurants to purchase and remove the garbage of such establishments; that they removed such garbage in a sanitary manner to places outside the city; and that such garbage was there used by them as feed for hogs. The plaintiffs claimed that the ordinance created a monopoly and was class legislation. The conclusion reached by the supreme court was that the city had authority to pass the ordinance in question and that the provisions thereof relative to garbage were reasonable.—Public Health Reports, Aug. 2, 1929.

City's Sewage Disposal Plant Not Enjoined.—(Texas Court of Civil Appeals; City of Wylie et al. v. Stone, 16 S. W. (2d) 862; decided April 10, 1929.) An action was brought against the city of Wylie and its mayor and aldermen to enjoin the operation of the city's sewage-disposal plant and to abate same, on the ground that its operation was a public and private nuisance. The jury's findings justified the conclusion that the plant as operated was a nuisance. The jury also found that the plant could have been located and operated in a practical manner on another site that would not have caused injuries to others similar to those inflicted on plaintiff; that plaintiff's land was depreciated in market value $5,000; and that the city would suffer $8,000 loss if an injunction were granted. The trial court abated the plant as a nuisance, enjoining the defendants from operating same at the location complained of. On appeal the judgment of the trial court was reversed by the court of civil appeals.

One of defendants' contentions was that, the legislature having authorized the governing authorities of the city to locate and establish the sewage plant, the nuisance, if any resulted from its operation, was legalized. The appellate court, however, held that the nuisance complained of did not belong to the category of those legalized, but, in a proper case, could be enjoined.

Another contention of defendants was that the trial court had erred in not directing a verdict in their favor because the evidence failed to show the existence of a nuisance, but this was overruled, for the reason that the jury's findings justified the conclusion that the disposal plant as operated was a nuisance.

In passing on another point raised by the defendants the court of appeals decided that "the jury should have been required to find in substance whether or not, under all the facts and circumstances, there existed a reasonable necessity for the location of the disposal plant at the point selected."

It was also contended that the plaintiff was not entitled to injunction relief as a matter of right, but should have been relegated to his action for damages. In discussing this phase of the matter the court said:

> It does not follow that every nuisance will be enjoined; courts will consider the equities pro and con. Ordinarily, where there exists an adequate remedy at law, a nuisance will not be suppressed by injunction; especially is this true in cases of the nature of the one under consideration, where the interest and convenience of an entire community is involved as against a private or personal inconvenience or loss that may be measured in dollars and cents.* * *
>
> One of the major functions of a municipal government is to insure proper sanitation and preserve public health; to this end the law, by express provisions of the statute and by many implications therefrom, has committed to governing authorities of cities, such as Wylie, the duty of establishing and operating sewer systems. They are authorized to purchase necessary lands, either within or without the city limits (art. 1108, R. S. 1925), and, when necessary, may acquire lands by condemnation proceedings (art. 1109b, R. S. 1925). Therefore, wherever these authorities act the presumption will be indulged, until overcome by a preponderance of evidence, that they acted in good faith, with due regard to the rights and interest of all concerned, and found a reasonable necessity for making the particular location. Courts are not authorized to substitute theirs for the judgment of authorities whom the law has clothed with exclusive authority to act, and their discretion, when exercised, should not be disturbed except in a clear case of abuse, which we do not find committed in this case.—Public Health Reports, July 12, 1929.

Garbage-Removal Ordinance Upheld and Refusal of Garbage-Removal Permit Sustained.—(Ohio Supreme Court; State ex rel. Moock v. City of Cincinnati et al.; Moock v. Same, 166 N. E. 583; decided May 1, 1929.) An ordinance of the city of Cincinnati provided as follows:

> That no person shall remove or carry in or through any of the streets, squares, courts, lanes, avenues, places, or alleys * * * any house dirt or house offal, animal or vegetable, or any refuse substance, from any of the dwelling houses or other places of the city. * * * unless the owner of the same shall have procured a permit so to do * * * prescribing the terms and conditions as may be deemed essential to the health and interests of the city. Provided, however, the provisions hereof shall not apply to any contractor with the city in relation to garbage.

The city contracted with a company for the collection and disposal of the garbage of the city for a 5-year period. The relator, who had contracts with various hotels, restaurants, and eating places to remove their garbage, was refused a permit to remove such garbage through the city. The relator owned a stock farm and utilized the garbage as food for animals. In actions instituted by him to compel the issuance of a permit and to enjoin interference with his removal of garbage through the city streets he attacked the above ordinance as being violative of both the State and Federal constitutions. The objections raised against the ordinance were that it denied the right of individual contract and conferred special privileges upon the contractor with the city, thereby creating a monopoly with respect to the garbage contract; that it permitted property to be taken

with compensation; and that the relator was denied the equal protection of the laws. The action of the city manager in refusing a permit to relator was challenged on the ground that his refusal was arbitrary and based upon mere whim and caprice, and it was contended that the city, having prescribed no conditions upon which permits should be granted, left their determination to the city manager and thereby invested him with legislative power. The supreme court decided that no rights of the relator, under either the State or Federal constitution, were violated by the ordinance or by the city manager's refusal to issue a permit thereunder.—Public Health Reports, July 19, 1929.

Sand and Gravel Requirements for Filters

Results of Investigations by National Sand and Gravel Association

FILTER sands have been found, from experience and laboratory investigations, to be required to possess fairly definite characteristics as to mineral composition, size and grading. They must be able to withstand the disintegrating influences of water, with which they are constantly in contact, and must be properly graded to insure efficient operation.

Sand Requirements.—Experiments have shown, according to Turneaure and Russell in "Public Water Supplies," that fine sands are considerably more efficient in removing bacteria than coarser sands and that within certain limits of size little difference in filtering efficiency is found. Also, finer sands cause a steadier and more uniform action over the filtering area, and disturbances due to scraping the filter are less likely to occur. On the other hand, the finer sands become clogged sooner than coarser ones and therefore involve more expense in cleaning. Allen Hazen in the paper, "Water Filtration at Washington, D. C.," which appeared in the Transactions, Am. Soc. C. E., Volume 57, 1906, page 326, under the authorship of Hazen, Allen and Hardy, established two factors to control the average size and uniformity of filter sands, which have come into general use. These are the "effective size" and the "uniformity coefficient."

Clear opening	0.41	1.0	0.84	0.59	0.42	0.30	0.25	0.18	0.15

Effective Size.—The "effective size" is that size than which 10 per cent of the weight of the sand is finer and 90 per cent is coarser. It is expressed in millimeters and may be found by making a sieve analysis of the sand and determining the theoretical size of screen through which 10 per cent of the sand will pass.

Table III shows the clear openings of certain standard sieve sizes of the American Society for Testing Materials:

Uniformity Coefficient.—The "uniformity coefficient" is the ratio of the size than which 60 per cent of the sand is finer to the "effective size." It will be seen that if all the grains are exactly of the same size, the "uniformity coefficient" will be 1. These factors can be most efficiently determined by plotting a sieve analysis curve.

Specifications for size and grading usually state that no grains shall be larger than some size, generally about 1 mm., and limit the percentage of material finer than a small size, generally less than 1/5 mm. Generally, no requirements as to shape of grain are given except that they should not be flat or elongated, since, so far as is known, rounded or angular grains are equally efficient. Sands having effective sizes ranging from 0.20 to 0.70 mm. are used, but the values most commonly specified range between 0.35 and 0.65 mm. Uniformity coefficients vary from about 1.25 to 2.50, with a maximum of 1.50 to 1.60 as the average requirement.

It is important that the sand grains in a filter bed shall not be disintegrated by the water with which they are constantly in contact. For this reason a good filter sand should be of high silica content. To insure durability of the sand grains, it is generally required that not more than 5 per cent shall go into solution in hydrochloric acid after 24 hours digestion or that the sand consist of at least 90 per cent silica. Most specifications also limit the amount of calcium and magnesium carbonate. The upper limit varies in the different specifications, but it is generally not more than 2 per cent. Some of the specifications place limits on iron, alumina, alkalies, loss of ignition, etc., but most of them do not include these detailed requirements.

Gravel Requirements.—Gravel is used in filters for water purification and also in the treatment of sewage. In water purification the purpose of the gravel is to serve as a base for the filter sand and to permit complete and rapid drainage of the filter. The size and grading, therefore, while important, can be varied over a considerable range. The gravel base is usually prepared in several different layers, each made up of one size of gravel, with the coarsest material on the bottom and the finest material in contact with the sand. Table II gives typical requirements as to grading of filter gravels used in water purifications by several different cities. The same precautions with respect to disintegration of the gravel particles by the water must be exercised as described under filter sands.

Mixing and Coagulation in Water Works Practice

General Theory of Coagulation of Chemicals in Water Purification

By M. P. HATCHER

Sanitary Engineer, Burns & McDonnell Engineering Co., Kansas City, Mo.

ALTHOUGH recognized as an important operation in the water treatment plant, the mixing and coagulation of chemicals has been given surprisingly little consideration in water works literature. There may be an explanation of this condition. Changing conceptions and the lack of comprehensive data on the subject may have contributed to its general neglect. Several investigators have given us information on reaction time and water velocities necessary in a general way to satisfactory results and some information is available on specific methods of mixing and coagulating but it may be said in general that the subject deserves more consideration than it has heretofore been given.

Mixing and Coagulation Defined.—There is some confusion in the use of terms. "Mixing" should be understood to include only the action necessary to adequately mix the chemicals with the water. Since we are dealing with coagulation the chemical is generally termed the "coagulant." "Coagulation" is defined as the process whereby the flocculate precipitate is permitted to unite and coalesce into larger and more rapid settling particles. The "retention period" of a mixing or coagulating unit is the extent of the time required for the water to pass through the device as determined by its displacement. "Velocity" as discussed in connection with mixing and coagulation is understood to represent the average velocity of the water in the cross-section normal to the axis of flow.

The discussion of "mixing and coagulation" will in this paper be confined to that pertinent to the coagulation of chemicals for the purpose of assisting sedimentation and filtration, excluding references to the problems involved in the application of lime in softening plants. The mixing of lime and its attending reactions presents problems which are specific and beyond the scope of this discussion. This paper also assumes favorable chemical and physical conditions known to affect the perfect coagulation of chemicals in the water.

The Baffled Basin.—The baffled basin probably deserves first mention in any dissertation on mixing and coagulating devices. This method has been in continued use since the scheme of coagulation was first conceived and still has many exponents among the designing engineers and plant operators.

There are two general types of baffled basins. The one more generally used is the under-and-over type which consists of a series of vertical passages constructed of wood or concrete in an outer structure usually built of concrete. The water passes from the inlet to the outlet through these compartments passing over and under successive partition walls. In the around-the-end type the axis of flow is horizontal. A smaller number of changes in direction are required in this type resulting in lower total head loss. Restricted passages required to maintain velocities are, however, more economically obtained in the under-and-over type of basin. The loss of head and velocity requirements generally fix very readily the type of baffled chamber to use in any particular plant.

Well defined ranges of velocity and retention period are necessary to the successful operation of this type of coagulating device. The proper velocities according to published data, vary from about .5 to 2.0 ft. per second with current engineering practice favoring velocities of about .7 to 1.0 ft. per second. Satisfactory operation of the baffled chamber requires that the velocities be self-cleaning thus avoiding the inconvenience of frequent removal from service. An alum floc will remain in suspension in a velocity of .6 ft. per second while a velocity of 1.0 to 2.0 ft. per second is required to suspend some of the clay silts and fine sand. It has been found that the coagulation process is simplified in plants along the Missouri River, if grit chambers are provided ahead of the mixing and coagulating basins. The removal of the heavier materials effects a two-fold improvement in the coagulation process. The possibility of deposit at nominal velocities is reduced and a source of interference with reactions is removed.

Langelier in his Sacramento experiments in 1921 reported a more rapid flocculation with velocities up to 1.5 ft. per second and a satisfactory flocculation with velocities up to 2.0 ft. per second. The writer, however, shares the opinion more generally held that such velocities may tend to decrease the size of flocculated particles; the advantage at least does not seem to offset the difficulties and costs attending higher velocities.

Retention period requirements in baffled basins vary from approximately 15 to 30 minutes. Higher temperatures are favorable to the shorter periods where longer periods are provided for the lower temperatures. Operators have found it advantageous to apply the chemicals at some intermediate point in the mixing and coagulating basin, eliminating thereby some of the possibility of destruction of the floc after it has reached its best condition.

The requirements of velocity and retention period impose their limitations on the use of the baffled basin as a mixing and coagulating device. Plant operating capacities may have a 100 per cent seasonal variation. If reasonably high minimum velocities are chosen for low operating rates, the velocities at maximum rates result in high head losses, in the baffled basin, making design both awkward and expensive. Head losses of 4 and 5 ft. are not unusual in this type of design. Head loss variation may be reduced if the mixing chamber is divided into two or more units using the number of units which will provide desirable velocities.

Baffled basins lack also the flexibility that is desired. Velocities in the compartments are fixed by plant operating rates. Variations in the character of the raw water may make desirable a change in velocity. This velocity can be obtained only by the use of the unit plan mentioned which tends to increase costs of structures. These shortcoming have led in many cases to the choice of other methods of mixing.

Mechanically Agitated Plant.—Coagulation is accomplished in a large number of water treating plants by mixing the applied chemicals with the raw water in tanks agitated by mechanically operated paddles. Flexibility in mixing velocity may be obtained by the provision for varying speeds in the stirring mechanism. Retention periods may be varied by the series or parallel operation of several tanks. The head loss through these units is of course small.

Velocities and retention periods in the mechanically agitated tank are made to conform to the requirements mentioned for the baffled chamber, the nominal velocity being assumed as that at the two-thirds radius point. Published data indicate that efficient mixing is obtained when the paddle area is 25 per cent of vertical cross sectional area of the tank. The writer knows of instances where satisfactory results are obtained with a single propeller type of paddles at the bottom of the tank. Several different arrangements of inlet and outlet have been used with success but theoretical considerations indicate that center inlet with circumferential take-off is preferable.

The Hydraulic Jump.—The hydraulic

jump has been studied with reference to its adaptability to the function of mixing by J. W. Ellms. The hydraulic jump may be described as the manner in which water is conveyed in restricted channels to a lower level with a consequent dissipation of energy through internal impact. The turbulence of the water at the jump brings about a condition which is ideal for the mixing of the small volume of chemical solution with the much longer volume of water. While the retention period is estimated to be only about 30 seconds the chemical reaction has been shown by experiments to be quite complete. The loss of head through the jump is less than that ordinarily required in the baffled basin, maximum efficiencies being claimed for head losses of .75 to 1.0 ft. This device is in use in a number of plants.

Spiral Inward Flow Method.—Mixing of chemicals and water is accomplished in a few plants by a method generally described as the spiral inward flow. Water is applied tangentially in a circular tank and is removed through a tap or bottom outlet pipe at the center. The arrangement of inlet and outlet causes the water to follow a spiral path from the periphery of the tank to the center. The displacement volume of the tanks provides in cases where this device has been used, a retention period of about 30 minutes. The water in following the spiral path from the periphery to the center moves with increasing velocity to the outlet. Considerable turbulence is produced by the swirling motion at the center just as the water is leaving the tank. Head loss requirements in this type of mixing device vary with the velocities obtained, allowances generally made ranging from 1 to 4 ft.

The types of mixing and coagulating devices in most general use have been enumerated and described. There are other devices, however, that should be mentioned briefly. The centrifugal pump, though not readily recognized as a mixing device, is sometimes used as such. Chemicals are applied in the suction and are mixed by the turbulent agitation produced in the pump. Mixing in some plants is accomplished by application of chemicals to the inlet lines to the settling basins. The Chain-of-Rocks filtration plant at St. Louis uses as a mixing device a series of underground concrete conduits wherein suitable velocities and retention are obtained. One manufacturer offers a mixing device which employs mechanical agitation with modifications of the usual methods. Another suggests the use of a device used in sewage disposal as an aerator. Practice indicates that some degree of coagulation can be obtained by a large variety of methods.

In order that we may more satisfactorily solve the problems of mixing and coagulation it is desirable that we analyze the processes involved with a view to determining the conditions most suitable to their accomplishment. The results of experimentation and practical operation now available should enable us to draw some general conclusions.

The original investigations of the hydraulic jump as a mixing device made by Mr. Ellms in about 1920 in connection with the report on water treatment at Milwaukee were reported without reference to the use of any adjunctive provision for coagulation. Nor was this need suggested in the earlier recommendations for its use. Excellent agitation was produced by the action of the hydraulic jump and it seemed reasonable to assume that a rapid and thorough distribution of the chemicals in the water might improve the process of coagulation. It is quite significant that the chemical reaction is completed in the hydraulic jump in the short time of 30 seconds. The contrast with the 30-minute period of the baffled basin pointed to distinct advantages for the hydraulic jump.

Later developments suggest a more complete analysis of the phenomena of mixing and coagulation. The experience of the writer has indicated that perfect coagulation requires something more than a completed chemical reaction. Mr. Ellms states in his later deductions that "gentle agitation produced by a velocity of flow from .75 to 1.0 foot per second hastens floc formation and produces a good aggregation of finely divided particles in 5 or 6 minutes."

Complete Coagulation Two Separate Steps.—The writer submits that complete coagulation should be considered as a process of two separate and distinct steps: (1) The chemical reaction of the coagulant and the treated water, (2) the physical change involving the aggregation of the flocculent precipitate and that overlapping of these two steps will not permit the best results. The first step is accomplished by any method which will bring the coagulant in close contact with all the water. This requirement points readily to violent agitation. The second step is accomplished best in velocities which will barely keep the floc in suspension. It is evident that violent agitation would be detrimental to the aggregation of floc and it is apparent that the chemical reaction would not be accelerated by the slow velocities favorable to the formation of the floc. It appears that only 5 or 6 minutes of gentle agitation are required to produce perfect coagulation after the chemical reaction has been completed. Since 15 to 30 minutes are required for complete coagulation in the baffled basin or mechanically agitated tank, we may reason that the first 10 to 25 minutes in these devices are consumed in bringing about the first step or chemical reaction which is completed by violent agitation in 30 seconds.

It is interesting to consider the methods employed in the devices described in relation to the method prescribed in a manner by the analysis of the general theory of coagulation as presented. If the chemical reaction can be completed in 30 seconds of violent agitation then excess capacities are being provided in baffled basins and mechanically agitated tanks where the same function is accomplished in a much longer time. The hydraulic jump appears to perform only the first step in the process. If the mixing process is followed immediately by the settling basins, the slow velocities therein will permit some of the floc to settle out before its full usefulness is developed. It seems desirable that a short period of gentle agitation follow this device. The spiral inward flow basin with a much larger capacity performs a service equivalent to that of the hydraulic jump but is not as efficient in the writer's opinion with equal energy losses. The action in this type of mixing device is, in fact, just the reverse of that desired for mixing and coagulation. The turbulent agitation is produced at the outlet where gentle agitation is required to preserve the floc. Low velocities prevail at the inlet where turbulence is desired.

Lack of uniformity in the fundamental principles of the mixing and coagulating devices in use indicate the necessity of further experimental study of these principles. The general theory of mixing and coagulation as outlined in this paper has served the writer as a means of comparing and studying the methods advanced from time to time.

Acknowledgment.—The above paper was presented at the 11th Texas Water Works Short School.

National Water Works Corporation Purchases $4,000,000 of Properties.—The National Water Works Corporation has acquired new properties valued at more than $4,000,000 in West Virginia, New Jersey and Pennsylvania. One company purchased was acquired from the United States Steel Corporation. This is the Mount Pleasant Water Co., organized in 1881, serving Mount Pleasant, Pa. Other Pennsylvania properties acquired are the Citizens Water Co. of Scottdale and the Gettysburg Gas Co. The West Virginia companies include the Buckhannon Water Co., Kingwood Water Co. and the Philippi Water Co., serving towns of the same name. In New Jersey, the Riverton & Palmyra Water Co. has been acquired.

Water Supplies in Michigan.—There are 331 public water supplies in Michigan, of which 112 are surface supplies. Fifty-two of these supplies are protected by chlorination only and an additional 27 are filtered. An additional 21 supplies are not supposed to be used for domestic purposes, being essentially fire protection supplies, mostly in small places.

Preammoniation at the Water Purification Plant of Springfield, Illinois

Experiences in Use of Ammonia As a Preventive of Chloro-Tastes

By CHARLES H. SPAULDING
Chief Chemist, Water Purification Plant, Springfield, Ill.

SINCE February, 1928, the Springfield water purification plant has used ammonia as a preventive of chloro-tastes with very satisfactory results. Prior to that time we were sometimes troubled with slight tastes associated with chlorination. While these were usually not sufficient to cause serious complaint, they did occasion remarks from time to time and left an opening for unfavorable criticism. Soon after beginning the ammonia treatment, we received a number of voluntary compliments on the improved taste of the water and occasionally find the impression that no chlorine is used at the Springfield plant.

The use of ammonia as an aid in disinfection is mentioned in standard texts. As a taste preventive, however, McAmis, at Greeneville, Tenn., seems to have been the first to use ammonia.

Preliminary Experiments at Springfield.—The bacterial loads in the raw water at Springfield have been excessively heavy. It was important in our case, therefore, that nothing should be done to lower the efficiency of chlorination, but that everything possible should be done to increase it. Some laboratory tests were then made to determine how disinfection would be effected. I used a pure culture of B. Coli added to samples of boiled distilled water and also to raw river water. In each case the disinfection accomplished in one hour was greater when ammonia was added to the water just before chlorination. The results on distilled water and raw water are shown in Table I.

These results were very encouraging, for preammoniation would thus rank as an additional measure of purification as effective in removing bacteria as other stages such as coagulation or filtration. However, we were disappointed in our next experiments in which lime was used as well as chlorine and ammonia.

Table I—Effect of Preammoniation on Disinfection with Chlorine

	Pounds per Million Gallons Ammonia	Chlorine	B. Coli per Cubic Centimeter	Per Cent Remaining After 1 Hour	Residual Chlorine
			Boiled Distilled Water		p.p.m.
A	0	0	29,500	100	
	0	1.0	535	1.8	
	0.5	1.0	20	0.07	
B	0	0	15,000	100	0
	0	1.0	50	0.3	0.10
	0.5	1.0	5	0.03	0.10
			River Water		
	0	0	39,000	100	0
	0	4	13,600	35	0.06
	2	4	650	1.7	0.06

Table II—Effect of Preammoniation on Chlorination of Lime Treated Water

Pounds per Million Gallons Lime	Ammonia	Chlorine	Total Count per Cubic Centimeter	Per Cent Remaining	Residual Chlorine p.p.m.	Alkalinity Phthalein	Total
0	0	0	25,500	100	0.0		194
1,200	0	0	24,500	96	0.0		
1,200	0	5	875	3.4	0.20	50	76
1,200	1	5	875	3.4	0.20	50	74
1,200	2	5	2,400	9.4	0.23	50	76
1,200	3	5	2,450	9.6	0.26	55	80
1,200	4	5	3,250	12.7	0.30	43	74

In this case the results after one hour of contact were less satisfactory with ammonia than without. The data on one group of tests with lime, ammonia and chlorine are shown in Table II.

The water used in this case was river water having a total count of 4,300 per cubic centimeter, to which a broth culture of B. Coli was added sufficient to give the initial count of 25,500 per cubic centimeter. Thus the organisms added greatly predominate, although they are not in pure culture. Lime, ammonia and chlorine were added in the order named while the samples were being stirred in a stirring machine for 5 minutes. They were then allowed to stand 55 minutes, after which stirring was resumed for 5 minutes and the samples taken up into the pipettes while being agitated. Alkalinities and residual chlorine were determined after plating out the bacterial samples.

The fact that a moderate causticity has little effect on B. Coli reduction in 1 hour is illustrated by this set of samples which was treated and titrated at room temperature. We have since found that no conclusions as to lime sterilization are valid unless temperature is stated, but in this case all samples were from the same batch and of the same size, and run at the same time, so that any temperature changes were of the same magnitude. Therefore, the comparison is accurate enough for the present purpose.

This experiment was twice repeated and samples taken at intervals up to 6 hours. The results confirmed the previous tests in general, but the indications were that still further reductions would be obtained with longer contact, and a fourth set was carried through to 21 hours and sampled five times during the run. The results in this set are shown in Table III.

As before, diluted broth culture of B. Coli was added to raw river water. The total count of the raw water before addition of the broth culture was 3,700 per cubic centimeter, and after the addition, 32,000. The results cannot be said to represent B. Coli efficiencies strictly for that reason. However, these comparisons have been made at times when the initial count of the raw water was only 0.5 per cent of the B. Coli added. The trend is always the same. Chlorine works best at lower pH values, that is, without lime. The addition of lime slows the chlorine sterilization, and the further addition of ammonia retards it still more. Yet in eight hours the four chlorinated samples have reached nearly the same point. Lime by itself is very slow in comparison. In this case the alkalinity was determined only at the end of 21 hours, and the water was exposed to recarbonation throughout the run. The alkalinity at the end indicates from 5 to 25 p. p. m. causticity and values of pH above 10 at least at the beginning of the run.

From these experiments it is evident that the best time to apply chlorine is prior to the addition of lime. It is plain that, if ammonia is used, a very marked increase in efficiency will result, providing the sterilization is complete before the addition of lime. It was not practical to realize these advantages without considerable additional capital investment at Springfield, and they were not attempted. The next best procedure is prechlorination to allow the maximum period of contact. Ammonia can be used in small amounts provided the contact period is sufficient. If the ammonia permits higher chlorine residuals without taste, then the retarding effect may be more than balanced by the free use of the sterilizing agent.

At Springfield, the nominal detention periods in the various stages of purification are as follows:

Mixing chambers		40 minutes
Clarifiers	1 hour	40 minutes
Settling basins	4 hours	
Carbonating chambers		30 minutes
Filters		30 minutes
Clear well (full)	4 hours	
Nominal total	11 hours	20 minutes

The actual flowing through time may be much less for a part of the water or for all of the water under certain circumstances such as low clear well or

Table III—Relation of Contact Period to Bacterial Reductions in the Lime-Ammonia-Chlorine Treatment
(Temperature Constant at 17.5°C.)

basins out of service. However, the plant is being operated at about 60 per cent of its capacity, so that the above figures should not be far from the facts on the average.

Four Classes of Tastes.—It was hard to establish definitely the sources of taste at Springfield for the tastes were not distinct as a rule. They were seldom sufficient to permit agreement by any two observers as to their quality, and for the most part passed unnoticed. Yet I believe we can now distinguish four classes. First, there was, occasionally, a medicinal taste at remote points on the distribution system sufficient to make the water unpalatable and to give credence to those who somewhat vaguely described a taste at other times. Second, a moldy chlorinous taste appeared occasionally after showers, usually associated with higher turbidity and higher chlorine dosage though not necessarily higher chlorine residual. A third class of tastes is associated with sudden thawing of ice over a large area of watershed following a sleet storm or frozen flood conditions. This is naturally rare, but may be extremely disagreeable. The fourth class of tastes is derived from algae and is not affected by ammonia treatment so far as we now know. With the possible exception of the first class, all of these are more correctly described as odors.

Under the circumstances it seemed as well to try the ammonia first on a plant scale, since it is simply applied, cheap and harmless, whether effective or not. The results were noticeable at once. The dose of ammonia was set at 5 lb. per day treating 7 million gallons of water. The quantity has been sufficient with the exception of a few brief periods when double the amount was used. During these periods it was possible to get a better idea of the effectiveness of the ammonia treatment through laboratory experiments which were made accordingly. For example, one set of bottle experiments is shown in Table IV.

Table IV—Experimental Treatment—Taste Prevention
(Temperature Maintained at 6°C.)

Sample Number	Chlorine, pounds	Ammonia, pounds	Taste After 40 Minutes	Odor After 40 Minutes	Residual Chlorine p. p. m.
1	6	0	2	1	0.20
2	6	1	1	0	0.23
3	6	2	0	0	0.26
4	8	0	3	3	0.30
5	8	2	1	0	0.35
6	8	3	0	0	0.40

Note: 1,200 lb. of lime and 200 lb. of alum were used in each case.

Samples were treated with chemicals as in the plant, except that chlorine and ammonia were varied. It is not possible to give a numerical value to taste with our present knowledge, and the figures in the taste and odor columns simply give the writer's opinion of the relative magnitudes. But where zero is recorded, all of several observers agreed taste was absent, while the value 3 indicates the consensus of opinion as to the worst of the group. Moldy and chlorinous would best describe the quality. The plant treatment on this day was 9.2 pounds chlorine and 1.6 pounds ammonia per million gallons, and no taste was present in the plant effluent. The experiment demonstrates that this class of tastes and odors is prevented at Springfield by the use of ammonia. Similar experience has been described recently by Harrison at Bay City.

The taste described as medicinal develops more slowly and is difficult to catch at the plant. A 24 hour composite sample of raw water, however, was examined by Mr. Theriault, chemist, United States Public Health Service, who reported a recovery of 1.2 parts per billion of phenol, and the fact that this amount is sufficient to cause a chlorophenol taste. Subsequently I have treated boiled distilled water with phenol in amounts from 2 to 50 parts per billion and have found that ammonia effectively prevents chlorophenol taste when used in the ratio of ½ lb. ammonia to 1 lb. chlorine. This conclusion is at variance with that of Harrison, whose results with ammonia in chlorophenol taste prevention were negative. There are several points of difference, however, in the way the experiments were made which may explain the discrepancy. He has used larger amounts of phenol and does not state what sort of water was used in the test. If it was not phenol-free, the difference in quantities might be still greater. Furthermore, in our case, lime water was added to the distilled water sufficient to produce a pH value of 9.6, which would approximate our plant effluent. Since pH makes a considerable difference in the activity of the chlorine, it may also affect the taste production. This point would stand further investigation. In our case cited the chloro-phenol taste developed somewhat from the start, but after 24 hours in the refrigerator it was very decided and roughly proportional to the phenol added. The samples pretreated with ammonia were entirely free from taste. These experiments and the plant experience indicate that, in a softening plant at least, ammonia may and in our case does prevent chloro-phenol taste.

No laboratory experiments have been made on the thawing ice complex which has occurred only once at this plant. As soon as discovered, the ammonia was increased from 0.7 to 1.7 lb. per million gallons in the raw water, after which the odor disappeared. The chlorine dose at this time was 7 lb. per million gallons. The following day complaints were received of the odor from hot water faucets. We are not sure whether this could have been entirely prevented by an earlier increase in ammonia dosage. There was no suggestion of chlorine in the odor. Using the hot test, both raw and filtered water will usually have some odor, more intense in the raw than in the filtered. For these reasons no definite conclusions could be drawn, but we were certain that the odor and taste of the cold water were immediately improved by increased ammonia.

Effect on Plant Operation.—It was shown by the preliminary experiments that no increased efficiency could be expected directly from preammoniation at this plant, but if chlorine could be used more freely, then indirect benefits might accrue. Table V includes the pertinent data summarizing the effect on plant operation.

It will be seen that chlorine consumption has increased, due to chlorinating raw water and due to the higher residual. On the other hand, less coagulant was used during the past year than previously. The net result is a saving of 41 ct. per million gallons treated, or 29 ct. if the cost of ammonia is included. The time required for disinfection is sharply brought out in the comparison of bacterial results at various stages in the process. For example, the clarifier effluent in the past year showed 33 per cent of the B. Coli index of the previous year. The water applied to the filters contained 16 per cent of the previous index, while the filtered water contained only 5.5 per cent of the former figure. The improvement practically stops at this point since the final chlorination now merely fills any sags in the chlorine residual.

Secondary Contamination.—In the tabulation for 1928-1929, the B. Coli

Table V—Comparison of Plant Records
Fiscal Year, March-February

	1927-1928	1928-1929
Number months prechlorination used	1	12
Total chlorine used, pounds per m. g.	2.9	6.1
Residual chlorine final, p. p. m.	0.12	0.18
Ammonia, pounds per m. g.	0.06	0.72
Coagulant, pounds per m. g.	185	82
Turbidity, p. p. m.:		
Raw	111	99
Applied	7.6	7.2
Filtered	0.04	0.01
B. coli per 100 cc.:		
Raw	19,757	21,122
Clarified	187	62
Applied to filters	134	22
Filtered	12.3	0.68
Chlorinated	0.36	0.25
City tap	0.12	0.11

index of the final effluent has had to be corrected and a considerable number of positives thrown out for the following reasons. The sudden appearance of B. Aerogenes in the discharge of a high service pump led to the discovery that the packing of this pump was contributing quantities of bacteria which in the ordinary routine would be classed as B. Coli. These bacteria, grown on Levine's eosin methylene blue agar, gave large convex confluent colonies usually with metallic sheen, when present, limited to small central area, the colonies appearing brown by transmitted light. The bacteria were nonsporing rods. Without carrying the identification further, I felt justified in classifying these as B. Aerogenes. From a sample of the packing taken from the pump, I estimated twenty billion B. Aerogenes per pound. New packing was then examined and found to contain the same organisms in great abundance. Eventually a packing was secured free from these bacteria, but meanwhile much water had gone through the pump. However, due to the chlorine residual maintained with the aid of preammoniation, the water from city taps showed very few of these bacteria. For example, one monthly record shows the following:

B. Coli Indices, August, 1928

Pump suction	0.15
Discharge	1.4
City tap	0.13

While these particular bacteria had no sanitary significance in our opinion, the case is cited as an illustration of the disinfecting effect of the residual chlorine which averaged 0.23 p. p. m. during the month. The effect is particularly valuable at this plant, located as it is on the bank of a river in which the B. Coli index is frequently over 100,000 per 100 cc. The clear well and flow lines extend below low water stage and much of the structure is surrounded with cinders or other loose material. Under flood conditions they are under as much as 18 ft. of pressure from without. A leak of 50 to 100 gal. per day would reduce a sterile water below standard unless it carried some protection.

Application of Chlorine and Ammonia.—The program which has finally been adopted with reference to chlorine and ammonia is as follows: Ammonia is added at the rate of 0.7 lb. per million gallons at the inlet of the raw water dosing well, where the detention is about 30 seconds. Chlorine is applied at the outlet of the dosing well in amount sufficient to produce a residual of 0.2 to 0.3 p. p. m. in the effluent of the clarifiers. As a rule, the residual drops slightly by the time the water has passed the filters, and additional chlorine is then added to bring the residual back between 0.2 and 0.3 p. p. m. If no drop has occurred, the second chlorination is omitted. As a rule, 1 lb. per million gallons is sufficient at this point.

The application of the ammonia has been made by solution prepared from anhydrous ammonia and delivered to the water from a small orifice below a tank holding 190 gal. of solution containing from 10 to 20 lb. of the gas. However, the present practice is to apply the gas directly through a needle valve and a bubble meter consisting of a bottle of light oil through which the gas rises. In this arrangement the rate is regulated by the number of bubbles per minute, 280 bubbles per minute being equivalent to 5 lb. per day. The rate of flow is extremely constant, the valve frequently requiring no adjustment over a 24 hour period. The capacity of the device as at present is about 10 lb. per day, which is the maximum and exceptional amount used. The ammonia tank stands on a scale, and the weight is recorded at regular intervals. The gas enters an alum solution line through which a small stream of water carries it into the dosing well. Whether or not the alum line is carrying coagulant is of no consequence.

Ammonia can be bought in many forms. Salts of ammonia could be applied from a dry feeder, but we have found the cost per pound of NH_3 is less for either aqua ammonia or anhydrous ammonia, which are very nearly the same delivered at Springfield, namely 15 ct. per pound.

In view of the advantages which we have found in preammoniation, either for taste prevention or for increased efficiency where lime is not used, this useful addition to water purification processes should find wider application. The method employed formerly was to prepare chloramine solution before addition to the water, and this troublesome procedure probably prevented more general use.

When Preammoniation Would Be Advantageous.—Bulletin No. 21 of Illinois State Water Survey contains analyses of municipal well supplies in Illinois. Taking the first hundred as typical, I find 23 per cent have less than 0.1 p. p. m. of NH_4. In chlorinating such waters, preammoniation will doubtless be found advantageous at times. On the other hand, the remaining 77 per cent contain up to 36.1 p. p. m. free ammonia as NH_4, with an average of 3.36 p. p. m., equivalent to 26.5 lb. ammonia per million gallons. Obviously it would serve no useful purpose to add ammonia to such water, although the knowledge of the ammonia content should throw considerable light on the behavior of chlorine in the water.

As compared with well waters, the rivers of Illinois are notably uniform in free ammonia content. Bulletin No. 5 (1907) of Illinois State Water Survey contains tabulations of sanitary analyses of municipal supplies, and I have arranged the ammonia data applying to surface waters in Table VI.

It will be seen that the average of each of the six stations is not far from the average of all, and the maxima and minima are not greatly divergent. A number of determinations which I have made on the Sangamon River at Springfield show but little variation from the value 0.090 p. p. m. N as free ammonia. Lake Michigan at Evanston, according to the above bulletin, contains slightly less than half as much free ammonia as the streams. We should expect, therefore, that, in general, the surface waters of the state will respond to preammoniation.

Conclusions. — Preammoniation increases the efficiency of chlorination of water having normal pH value and low ammonia content.

Preammoniation prevents chlorotastes, including chloro-phenol tastes in a lime softening plant.

With high pH values, considerable time of contact, as much as eight hours, should be provided if maximum sterilization is required.

Ammonia is simply and cheaply applied with no undesirable after-effects necessitating special vigilance.

Chlorine residuals sufficient to overcome subsequent contamination are feasible when ammonia is present.

Acknowledgment. — The foregoing was presented May 14 before the Illinois Section of the American Water Works Association.

Sludge Disposal at the Calumet Sewage Treatment Works

Experiences at the Imhoff Tank Plant of Sanitary District of Chicago

By A. H. GOODMAN and C. E. WHEELER

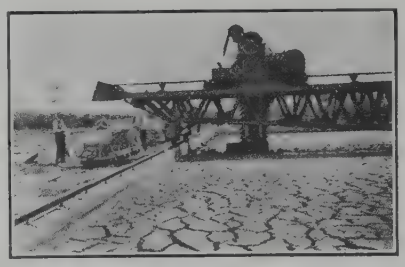
Respectively Plant Sanitary Engineer, and Assistant Plant Sanitary Engineer, Calumet Sewage Treatment Works, Sanitary District of Chicago

THE Calumet Sewage Treatment Works of the Sanitary District of Chicago, located at 125th St. just west of Cottage Grove Ave., is designed to treat the sewage of Chicago south of 87th St. and in addition, that of Blue Island, Riverdale, Dolton and several other small municipalities at some future period. The combined (domestic and storm water) sewage is brought by intercepting sewers to two pumping stations, one at 95th St. near the lake and the other at 125th St. and Michigan Ave. The flow from the latter station comes to the treatment works. The design capacity of the plant is 56 m. g. d. with an allowance for a 50 per cent increase for storm flow.

The sewage is measured by a Venturi meter and then passes through a rack screen with 1-in. openings equipped with a mechanical cleaner. It flows next through grit chambers which are equipped for cleaning with a grab bucket on an electric hoist working from a gantry crane. The velocity in the grit chamber is maintained between 0.75 and 1 ft. per second. The sewage then passes to 30 Imhoff tanks each 103 ft. 6 in. long by 34 ft. 6 in. wide, and 25 ft. deep. The sedimentation compartment is divided into 3 bays. There are 3 sludge hoppers in the shape of inverted frustrums of square pyramids. Gas vent area is 17 per cent of the total surface area.

Operation of Tanks.—Operation of the plant began on Sept. 12, 1922, when sixteen Imhoff tanks were put into service. The remainder of the Imhoff tanks were started on Dec. 16, 1922. The sewage treated is mainly domestic and somewhat weak in character. In 1924, however, paint waste began to cause trouble. Large quantities of oil are found at times. No foaming trouble has been noted from the sixteen tanks started in September but the tanks started in December went through a violent foaming period of about six weeks the summer of the next year, 1923. Since 1923 there has been no foaming in any of the tanks.

The tanks are arranged so that the direction of flow may be reversed. This is done regularly, the length of time in one direction rarely exceeding 2 months. This program appears to give satisfactory distribution of solids throughout the length of the tanks. Routine determinations of sludge levels are taken at 3-month periods in each hopper. These levels are taken with a common pitcher pump, equipped with a suction hose, which is lowered through the supernatant liquor underlying the scum in the gas vents until sludge is encountered. This method has proved to be the most dependable of any tried.



Sludge Removal Machine at Calumet Sewage Works

Disposal of Imhoff Sludge.—Sludge is removed from the sludge hoppers by an air lift. Water rings of perforated brass pipe are installed in each sludge hopper to stir up heavy sludge and to aid its movement, also to allow of some mixing of the digesting sludge mass. After being pumped from the hoppers the sludge runs by gravity to the original drying beds, which are adjacent to the tanks, or to two—150 gal. per minute Jennings pneumatic ejectors, which force the sludge to the additional beds installed in 1927. The total sand bed area at the present time is equal to 0.67 sq. ft. per capita on the designed population of 225,000 people or about 1.0 sq. ft. per capita on the present population. Sludge as wasted varies in moisture from a yearly minimum of 87.2 per cent water to a yearly maximum of 89.1 per cent. Average moisture of sludge over five years of operation has been 87.8 per cent.

Sludge is usually placed on the beds to an average depth of 9 to 11 in. At certain times of the year, in order to use the drying area to greater advantage, the depth is increased to 15 to 16 in. Filling 9 to 11 in. in average good drying weather permits the sludge to be removed from the beds in about two weeks, with a yearly average moisture content varying from 39.3 to 55.1 per cent. Sludge has been removed by hand with forks and carried away by a system of narrow gage railroad tracks and dump cars. The original sand beds are 66 ft. long and vary in width from 17 to 20 ft. The 24 in. gage industrial track is installed lengthwise in the center of each drying bed with a complete system of switches and main track for assembling trains outside. The new beds are 105 ft. long and 65 ft. wide with a similar track system going into the beds, 5 rows of track to each bed, making the distance between center line of tracks 22 ft. Motive equipment consists of three Plymouth industrial gasoline locomotives and forty ¾-yd. dump cars.

The sludge is removed from the beds by hand forking into the cars, the cars are assembled and hauled to a sludge pump for disposal at the north end of the property. This dump was built up on the clay spoil from the plant construction and is about 700 ft. long. The track is laid the long way of the dump. As the sludge accumulates it is pushed over the edge of the bank by a Parson's backfiller. This has facilitated greatly the handling of sludge at the spoil bank, and with the improved distribution the track must be moved not more than once per year.

Some figures on sludge quantities and analyses may be of interest.

Imhoff Sludge Removal Data

Year	Wet Sludge Pumped from Tanks Total Cu. Yd.	Moisture, %	Dry Sludge Removed from Beds Total Cu. Yd.	Moisture, %
1923	7557	87.2	3289	44.1
1924	13039	87.3	3938	41.2
1925	16073	89.1	7080	46.7
1926	18323	87.3	7524	51.3
1928*	13999	88.1	6014	55.1
1927	19864	87.5	7990	39.3
Total	88855	526.5	35835	277.7
Av.		87.8		46.3

*Plant shut down 4 months.

Total dry solids removed for six years—34,243,630 lb.

Dry sludge weight per cubic yard as removed 1,500 lb.

Sludge Analysis

Sample and Year	Moisture, %	Nitrogen, %	Volatile, %	Fixed %
Sludge from beds—'24	53.3	1.68	41.6	58.4
Sludge dump top—'23	43.3	1.33	32.8	67.2
Sludge dump intr.—'23		0.98	27.9	72.1
Sludge from beds—'27	52.45	2.00	40.2	59.8
Sludge dump top—'26	30.22	1.48	38.7	61.3
Sludge dump intr.—'26	46.86	0.99	42.6	57.4

Record of Temperatures, Imhoff Tanks.—The lowest average monthly temperature in the sludge compartment over the period of our record has been 40° F., which has also been the lowest temperature for the flowing-through compartment. The maximum for the sludge compartment occurred in September, 1926, and was 70° F., while the maximum for the incoming sewage on several occasions during August and September has been 69° F.

For the three years over which we have complete records the following condition prevailed.

No. of Months	1925	1926	1927
Below 50° F.	5	4	2
Above 50° F.	7	8	10
Above 60° F.	4	6	4

These figures indicate that in Chicago and vicinity for an average of 4 months per year temperatures in unheated digestion tanks will be so low as to retard digestion processes very noticeably.

Digestion of Settled and Activated Sludge.—Digestion of primary sludge and excess activated sludge has been studied on a large scale. These tests extended over a period of three years. An average of 1.75 m. g. d. of sewage was settled in an Imhoff tank and the effluent was treated by the activated sludge process. The waste activated sludge was returned to the incoming sewage of the Imhoff tank.

After six months of operation it was apparent that additional sludge digestion capacity was needed to provide storage for the bulkier sludge from the activated sludge process. An additional Imhoff tank was used to supply the extra capacity required. This was operated as a separate digestion tank. The partially digested sludge was pumped over into this second Imhoff tank where the digestion was allowed to continue until the sludge was in satisfactory condition for drying.

The activated sludge was wasted as slowly and as gradually as possible in order to obtain as nearly as possible continuous mixing of activated with fresh sewage solids in the Imhoff tank. Occasionally the flow of activated sludge had to be shut off so as not to withdraw too much from the activated sludge process. The combined sludge after digestion had all of the characteristics of Imhoff sludge produced at the plant except that it averaged about 2 per cent higher in moisture content as drawn, contained somewhat higher total nitrogen, and cracked into much smaller sections in drying.

Average figures for the entire period of experiment gave the following results: 9.4 cu. yd. per m. g. of activated sludge at 98.55 per cent moisture mixed with 2.2 cu. yd. per m. g. of fresh sewage solids at 90 per cent moisture (est.) gave 2.4 cu. yd. per m. g. of combined sludge at 89.8 per cent moisture. This amounts to an 80 per cent reduction in volume. The digestion of dry solids was based on determinations of suspended solids in the influent and effluent of the Imhoff tank and on the actual quantity of activated sludge wasted. These data over a long period indicated 32.5 per cent digestion of suspended solids.

This experiment at the Calumet Sewage Treatment Works indicated the practicability of satisfactory digestion of Imhoff and activated sludges. This procedure was adopted in the design of the West Side Treatment Works, where the waste activated sludge of the North Side Treatment Works will be mixed with the fresh incoming sewage of the West Side plant and the mixed settled solids digested.

Mechanical Removal of Sludge.—Mechanical sludge removal from drying beds became important to the Sanitary District with the development of the West Side project. Experimental work has been carried on at the Calumet plant for the last 3 years to help in the solution of this problem. Small-scale work was started with a roughly built cleaner which worked on a narrow gage platform car. This consisted of a set of fingers bolted to a sheet metal tray equipped with an angle-flight elevating mechanism for moving the sludge up the pan to the dumping position. The machine was pulled through the bed by a car-puller. The width of the strip taken was approximately 4 ft. This machine demonstrated the feasibility of the plan and the fact that sludge could be taken off a drying bed mechanically without removing excessive quantities of sand with the sludge.

The next development was a machine of quite similar principle with a span of approximately 16 ft. Different shapes of elevating angles were used.

In the fall of 1928 a practical working machine was constructed to operate over six of the new sludge drying beds (105 ft. x 65 ft.). This machine is a double truss structure spanning the width of the beds and supported by rails on side walls. The narrow gage track system was removed from the drying beds. The machine traverses the total length of the six beds. The equipment is completely motorized, receiving its power from a trolley system extending lengthwise of the beds.

The machine was developed by the Evers-Sauvage Engineering Co. It consists of a series of specially shaped buckets working on an endless vertical chain quite similar to a ditch digging machine. The buckets are equipped on their cutting side with sharpened teeth and cut a strip of sludge about 4 ft. wide across the narrow dimension of the beds. The carriage carrying the buckets moves into the sludge by a drive which is independent from that which runs the bucket elevator. The buckets dig into the sludge at a speed of 20 ft. per minute. The speed of the elevator is sufficient to raise the sludge as rapidly as it is forced into the buckets. The buckets dump into a short cross belt conveyor which in turn discharges onto a large belt which travels across the width of the bed and discharges into the narrow gage dump cars. These cars are pulled along by a gasoline locomotive as the sludge machine moves forward on the bed.

In some preliminary tests that have been made on the machine this summer the capacity on sludge of about 55 per cent moisture and from 5 to 6 in. deep appears to be about 1.25 cu. yd. per minute. The buckets can be elevated or lowered to strike the exact sand level. They appear to pick up an almost negligible quantity of sand. There are several ways in which the capacity of this machine may be increased.

Collection of Gas from Imhoff Tanks.—Closely connected with the problem of sludge disposal is the collection of gas from digesting sludge. One Imhoff tank was equipped with gas collectors in the gas vents, the total number of separate vents covered being 24. Half of these were equipped with collectors of the Imhoff type consisting of a submerged collector sloping upward from ends to center where a small opening is provided, covered with a screen of loosely laid tongue-and-groove material. This screen is to hold back scum and permit the passage of gas into the small collecting can. The Sanitary District type consists of a longitudinal sheet metal collector, which covers the whole gas vent area. There is a water seal around the edges and simple deflectors beneath, to direct the rising gas into the collector. On this type no screen of any sort is provided to check the rising of the scum.

The formation of scum under both types of collectors has been the principal operating difficulty in collecting the gas. The screens on the Imhoff type plugged very shortly after this tank was put into operation. They were then removed.

Gas production varies greatly in unheated tanks due to the wide variation in temperature. In this climate the month of maximum production is usually September and the minimum February. The quantity of gas produced in September may be from 5 to 10 times as great as the production in February. The average production for the year 1927 was 0.406 cu. ft. per capita per day and 5.15 cu. ft. gas per lb. of volatile matter. The analysis of the gas for a period of one year gives the following figures:

Carbon-Dioxide		Oxygen		Methane		Nitrogen		B.T.U./Cu. Ft.	
Max., %	Min., %	Max., %	Min., %	Max., %	Min., %	Max., %	Min., %	Max.	Min.
26.5	8.2	0.8	0.1	84.1	64.0	18.3	2.0	848.6	650.8
A typical complete analysis being:									
14.2		0.3		74.4		11.1		750.7

Phenol Tastes and Odors in Water Supplies of Ohio River Cities

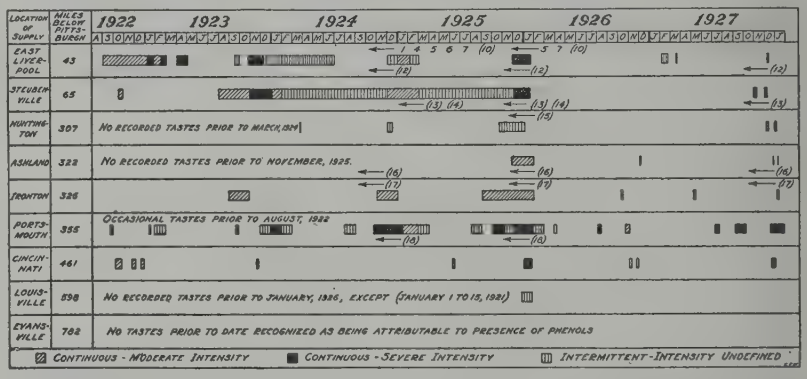
Reduction in Intensity May Be Due to Process of Natural Biochemical Oxidation

By H. W. STREETER
Sanitary Engineer, U. S. Public Health Service

FOR several years past, and particularly since the war, tastes and odors of such a nature as to identify them with the presence of phenols and allied substances have been experienced, with varying frequencies, in the water supplies of cities located on the inland waterway systems of the middle western and easter portions of the United States. Tastes of a similar nature have appeared in water supplies located in other areas, both of this country and of Europe. In no instance, however, has this difficulty been more serious or affected larger groups of population than it has in the area adjoining and tributary to the upper portion of the Ohio River, which drains a highly industrialized region serving as a center of the coal, steel, and allied industries.

Cause of the Taste and Odors.—A search for the specific causes of the tastes and odors above described revealed that fact that during and since the war period the coke-producing industry has been abandoning the use of the older "beehive" ovens for burning coke and has been substituting for them modern by-product plants, from which valuable substances are recovered from the gases which formerly went to waste in the atmosphere. The residues from some of these recovery processes, notably those concerned with the manufacture of benzol and ammonia, have been found to contain very considerable amounts of tar, phenols, cresols, creosotes, and similar substances, which, when discharged into sources of water supplies, produce characteristic "medicinal" tastes and odors in them.[1] Although other classes of wastes, notably those derived from producer-gas plants, have been found to contain phenols and similar taste-producing substances, the total amounts of phenols resulting from the operation of coke by-product plants are so much greater than those produced by any other single industry, and their production takes place in such highly concentrated areas, that a large share of the responsibility for the difficulties caused by wastes of this class logically has been attributed to them.

Aggravated Conditions Along the Ohio River.—In the upper portion of the Ohio River Basin, and especially along the Ohio River proper, the situation has been aggravated by the fact that, in order to produce bacterially safe effluents for drinking purposes, municipal water purification plants are forced to resort to continuous chlorination of the water in addition to coagulation, sedimentation, and filtration. This condition is due primarily to the large volumes of untreated sewage that is being discharged into this river system at the present time. The addition of chlorine to water containing small amounts of taste-producing phenols has been found to intensify the tastes caused by these substances, probably owing to the formation of chloro-phenol and allied compounds which are known to have exceptional taste-producing properties.



Key to locations of coke by-products plants:
1. Fairmont, W. Va. 2. Clairton, Pa. 3. Johnstown, Pa. 4. Warren, Ohio. 5, 6, 7. Youngstown, Ohio. 8. Farrell, Pa. 9 Pittsburgh, Pa. 10 Midland, Pa. (11) Woodlawn, Pa (12) Wierton, W. Va. (13) Follansbee, W. Va. (14) Benwood, W. Va. 15 Canton, Ohio. (16) Ashland, Ky. (17) Ironton, Ohio. (18) Portsmouth, Ohio. Numbers in parenthesis refer to plants located directly on the Ohio River; numbers not in parentheses refer to plants located on tributaries

Fig. 1—Graphical Record of the Appearance of Phenol Tastes in the Water Supplies of Designated Cities Located in the Ohio River, with Relative Location of Coke Byproducts Plants Discharging Phenol Waste Into the Ohio River

In March, 1924, a report was prepared by Sanitary Engineer H. R. Crohurst, of the Public Health Service, giving the results of a survey which he made of the water supplies affected by tastes of phenol origin and of the industrial plants producing phenol-bearing wastes within the Ohio River Basin. In his report, 17 coke by-product plants were listed at that time as discharging wastes of this character into the Ohio and it tributaries. Later reports submitted by the departments of health of Pennsylvania, Ohio, West Virginia, and Kentucky, at a joint conference held in February, 1926, indicated that about the same number of plants as that above named were actively discharging phenol wastes at that time in this river basin.

Records of Appearance of Phenol Tastes.—Systematic records of the appearance of phenol tastes in Ohio River water supplies have been maintained, since late in the year 1921, by operators of municipal water purification plants located along the river. These records have been collected by the United States Public Health Service from time to time and brought together for comparison. A comparative summary of these records, showing the period and, roughly, the relative intensities of phenol tastes observed in Ohio River water supplies, is shown graphically in Fig. 1, which has been plotted from the records thus collected. In this diagram are shown also the approximate locations, with respect to the various water intakes, of coke by-product plants discharging phenol wastes into the Ohio River and its tributaries at intervals during the period 1924 to 1927, inclusive. It will be noted in this connection that of the 17 plants indicated as discharging phenol wastes in 1924, only four were stated as remaining actual contributors in 1927.[2] The reduction was brought about as the result of joint efforts of the authorities of the Ohio River states and by manufacturers, following conferences held in 1924, 1925, and 1926. The work thus accomplished has been described so fully elsewhere[3] that it is

[1] These taste-producing substances will be designated hereafter by the single term, "phenols."

[2] In a recent paper by Waring (see reference in footnote 3), he indicates that, in the autumn of 1928, this number had been further reduced to two plants, located, respectively, at Wierton and Follansbee, W. Va.

[3] Waring, F. H.: Results Obtained in Phenolic Wastes Disposal under the Ohio River Stream Conservation Agreement. American Journal of Public Health, vol. 19, No. 7, July, 1929, pp. 758-770.

unnecessary here to discuss that phase of the subject.

On referring to Fig. 1, it will be noted that up to the end of the year 1925 tastes of phenolic orgin were present at frequent intervals and, during some periods, almost continuously, in the water supplies of East Liverpool and Steubenville, located, respectively, 43 and 65 miles downstream from Pittsburgh, and in those of Ironton and Portsmouth, located 326 and 355 miles downstream from the same point. At Ashland and Huntington, located short distances upstream from the Ironton-Portsmouth zone of the river, but about 240 miles downstream from Steubenville, the recorded tastes were considerably less both in frequency and intensity; likewise at Cincinnati, located about 106 miles downstream from Portsmouth. At Louisville, 130 miles downstream from Cincinnati, no tastes of phenolic origin were recorded until December, 1925, and January, 1926, when a wave of these tastes, of unusual intensity, extended down the river to this point.

change in the status of such tastes occurring after the winter of 1925-26 is further indicated by the following tabulation showing the months of the years 1924 and 1925, as compared with those of 1926 and 1927, in which tastes of phenolic origin were recorded in the water supplies of various Ohio River cities:

City	Total number of months in which tastes occurred 1924-25	1926-27
East Liverpool	11	4
Steubenville	24	3
Huntington	5	2
Ashland	3	3
Ironton	7	3
Portsmouth	13	8
Cincinnati	2	4
Total	65	27

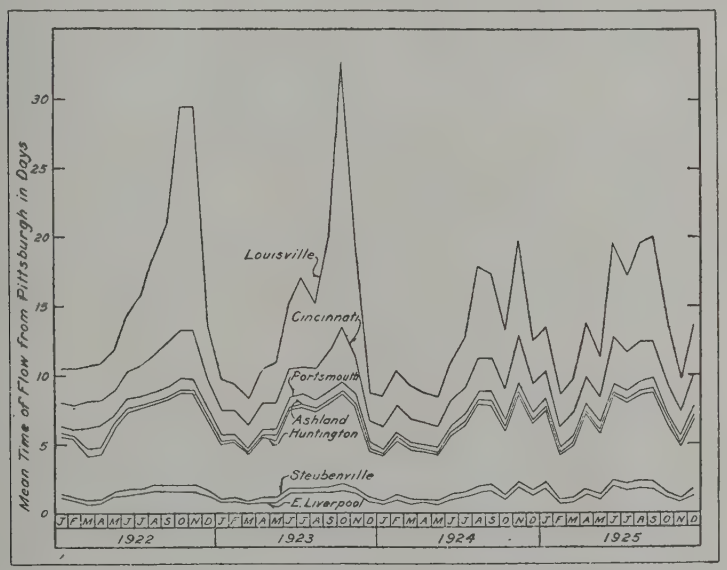


Fig. 2—Seasonal Variations in Times of Flow of the Ohio River from Pittsburgh to Designated Cities Downstream

Cooperative Control Efforts by States.—Following the December-January phenol wave of the winter of 1925-26, a renewed cooperative effort was made by the states of Pennsylvania, Ohio, West Virginia, and Kentucky to bring about the elimination of phenol-bearing wastes from the Ohio River system. The results of this effort, which left only four recognized sources of phenol pollution in the Ohio River at the end of the year 1927, were evidenced, as is shown in Fig. 1, by a well-marked diminution in the frequency and intensity of phenol tastes in Ohio River water supplies, the only outbreak of serious proportions during this period occurring in December-January of the winter of 1927-28. The figures given in the table fail to show the true contrast existing in the prevalence of tastes during the two periods indicated, because they do not take account of the greater intermittency and less intensity of such tastes during the later period. If these factors could be weighted properly, they probably would show that a reduction amounting to fully 90 or 95 per cent has taken place since the end of 1925.

Tendency to Natural Purification.—Aside from the foregoing indications, the conditions illustrated in Fig. 1 are of considerable scientific interest in that they afford fairly definite evidence that the concentration of taste-producing phenols in the river has had a marked tendency to become reduced progressively, in passing down stream, to a greater extent than can be accounted for by increased dilution or by any other wholly physical influence. The evidence at hand suggests very strongly, in fact, that a large part of the reduction observed is due to some natural process of purification, similar in its general mode of action to other phenomena commonly associated with the self-purification of streams.

The tendency above noted is indicated, broadly, (a) by the sharp reduction in the prevalence of phenol tastes observed in water supplies located at considerable distances down stream from sources of phenol pollution, as compared with their prevalence in supplies located in the more immediate vicinity of such sources of pollution, and (b) by the marked seasonal variations in the relative frequency and intensity of phenol tastes occurring in all of the Ohio River water supplies and especially in those further removed from sources of phenol pollution.

On referring to Fig. 1 it will be noted that during concurrent periods phenol tastes occurred less frequently at Huntington, Ashland, Cincinnati, and Louisville, all of which were located at distances of more than 100 miles downstream from recognized sources of phenol pollution, than at East Liverpool, Steubenville, Ironton, and Portsmouth, which were located within short distances of such sources of pollution. The reduction observed has been particularly striking between Steubenville and Huntington, a distance of 242 miles, and between Portsmouth and Cincinnati, a distance of 106 miles. In the latter instance the reduction in the frequency of phenol taste prevalence, amounting to over 80 per cent, occurred in a river stretch in which the total amount of dilution water added to the Ohio, mainly through the Scioto River at Portsmouth, ordinarily is less than 10 per cent. In the former case, it likewise could be shown that the reduction experienced in the prevalence of phenol tastes was far greater than would be accounted for in terms of added dilution water.

It further will be noted in Fig. 1 that although phenol taste-producing substances penetrated throughout the Ohio River as far as Cincinnati on several occasions during the winter and early spring, they did not appear during the summer or early autumn at any of the cities removed by any considerable river distance from points at which phenol wastes were discharged into the river. If dilution were a dominating factor in these variations, their trend would be expected to be exactly the opposite of that actually observed, since the maximum flow of the Ohio River occurs in the winter and early spring.

Although no data are at hand concerning the seasonal trend of production of phenolic wastes by coke by-product plants, it hardly would appear, from the nature of the industry, that such wastes could be produced in sufficiently greater volumes during the winter-spring season, as compared with the summer-autumn period, to account for the wide seasonal variations above noted.

The condition shown in Fig. 1 is entirely consistent, on the other hand, with the view that the seasonal and

geographic changes in phenol tastes prevalent observed in the various Ohio River water supplies have resulted largely from some natural process of purification which, though limited in its action, like all other processes of stream self-purification, is sufficiently powerful to bring about a marked progressive reduction in the density of phenols in stretches of the river relatively free from increments of pollution of this character. Thus, it is noted that the maximum reduction has occurred during the summer and early autumn seasons when the Ohio River usually reaches its lower stages, and the effect of longer times of flow, as illustrated in Fig. 2, is accentuated by that of higher stream temperatures. In general, the period in which evidences of phenol pollution, as gauged by the appearance of tastes in water supplies, have penetrated to the downstream points far removed from the sources of such pollution, have occurred coincidentally with shortened times of flow, as indicated in Fig. 2, and with relatively low stream temperatures, both of which conditions tend, in general, to bring about reduced natural purification effects in streams.[4]

Progressive Reduction May Be Due to Natural Biochemical Oxidation.—In the foregoing connection reference may be made to recent studies by Mohlman[5] and his associates, which have shown that the oxidation of phenols, which can be accomplished by ordinary biological processes of sewage treatment when phenolic wastes are mixed in proper proportions with sewage, is essentially a biochemical phenomenon, proceeding along definite time-function curves at rates varying closely with the temperature, being greater at higher temperatures, and vice versa. As the behavior of phenols in the Ohio River has been consistent, except in degree, with their reactions to artificial processes of oxidation, it would seem quite logical to infer that the progressive reductions thus observed under natural conditions may be due to a process of natural biochemical oxidation similar, in its general characteristics, to that which proceeds more intesively under artificial conditions.

If the foregoing theory is correct, its lesson is fairly obvious in so far as its application to problems involving the elimination of sources of phenol pollution of water supplies is concerned. In cases in which water supplies are subject to continuous or frequent pollution by phenols, the important sources of such pollution are more likely to be found in the near vicinity of the supply than at any considerable distance. If, however, they are subject only to occasional pollution, occurring more especially during the colder season or, in streams, coincidently with high river stages, the source of the trouble probably is located at a more distant point. In undertaking any general program of remedial measures looking to the relief of phenol pollution of water supplies, located along an entire stream, the maximum immediate benefit of such measures probably will be attained by eliminating, first, all sources of phenol pollution located directly on the stream in question or in the lower reaches of tributaries discharging into the main stream above the points at which the water supplies affected are located. The history of phenol tastes in Ohio River water supplies, both during and following the institution of progressive remedial measures by the bordering states, has afforded an interesting confirmation of the principle stated, as is indicated in Fig. 1.

The effectiveness with which the pollution of Ohio River water supplies by phenol wastes has been brought under a large measure of control within the comparatively short period of time intervening since the year 1925, constitutes one of the brightest pages in recent sanitary history. Accomplished, as it has been, without any coercive legislation, but through cooperative effort by the federal and state governments and the industries concerned, it augurs well for the future solution of some of the larger problems of stream pollution now confronting the nation. Although pollution of the Ohio River system by phenol wastes has not been completely eliminated, as evidenced by occasional "spills" which have occurred during the past year or two, it has been curbed to an extent such as to justify the expectation that in the near future it will cease to be a major problem along this important waterway. A generous measure of credit is due to those whose joint efforts have brought about this fortunate result.

The Importance of Controlling the Raw Water

By A. L. GOSNELL
Filtration Plant Operator, Laurel, Md.

In presenting this article it is the writer's intention to bring out the importance of controlling the raw water where it is possible to do so.

The filtration plant at Laurel, Md., has a capacity of 500,000 gal. per day. The lake, or raw water reservoir, has a capacity of 7,000,000 gal. and is situated about a mile and a half from the plant. The stream entering the lake is derived from springs, and has a flow of about 500,000 gal. per day. This water, under favorable conditions, is exceptionally easy to control, yet under unfavorable conditions control borders on impossibility. The detention period in the lake is 14 days. The lake was made more than thirty years ago and the weeds, grass and bushes have been permitted to run wild, with the result that a favorable medium for algae growths has been produced.

It is customary to use copper sulphate to control algae growths, but we have learned that when trouble exists, the proper thing to do is to find the cause and remove it. Of course the proper thing to do in this case would be to clean up the filth and remove the weeds and grass around the lake. Cleanliness is of much importance even in the raw water. However, when the necessary cleaning is not done, it is necessary for the operator to take other steps. Past records revealed that during the winter months the pH of the water is about 7.0 and that from June to December it is about 6.0. It was the opinion of the writer that if the pH of the raw water could be held near 7.0, the carbonic acid would be eliminated, thereby cutting off the food supply of the growths and retarding their development.

In June, 1928, conditions were bad. A turbidity of 80 required an alum dosage of 1 g.p.g. for treatment. In an attempt to improve conditions, the lake was treated with hydrated lime. One hundred pounds of lime was spread around the entire circumference of the lake, extending about 5 or 6 ft. out from the shore. One bag of lime was tied up in a canvas bag with a few holes punched in it and anchored in the stream about 100 ft. above the inlet to the lake. The bag of lime was renewed every month from June to December.

The effect of the lime was noticeable almost immediately. A concrete dam that had formerly been covered with a slippery scum became clean and safe to walk on within a few days, the dose of coagulant was cut in two and the water was very easy to control. The treatment had only one objectionable effect: the oxygen content was increased to such an extent that the filters became air-bound in a 2½ to 3-hour run. However, this slight objection was overbalanced many times by the improved condition of the water. About 12 months were required to come to a decision as to the effect of the lime treatment. From July 4 to July 22 of this year the average turbidity was 150, with a maximum of 300, and at no time during that period did the alum dosage exceed ¾ g.p.g. This is in strong contrast to the dosage of a year ago, when a turbidity of 80 required 1 g.p.g.

Unusual Features of Filter Plant Design

Special Arrangements for Proposed Plant of Niagara Falls, Ont.

By F. A. DALLYN
Consulting Engineer, Toronto, Ont.

AS a preamble to this paper, I must state that the plant to which my remarks relate has not as yet been built. The design has been complete for something more than a year, and tenders were invited for the building in the spring of this year; but owing to misunderstandings and political and other controversies, the work has not yet gotten under way.

The Supply.—At Niagara Falls we have a Great Lakes water, taken from one of the connecting rivers at a point of high velocity—a water subject to some pollution, never very intense, and subject to turbidities which might be common also to such plants as Cleveland, Erie and Buffalo.

Lake Erie is a relatively shallow lake and storms promote a continuing turbidity, which sometimes exists for a week at a stretch. Ordinarily the water is fairly clear, possessing sufficient alkalinity to react with the aluminum salts without occasioning any aftermath of red water difficulties. The velocity of the river suggests that some difficulty might be encountered from frazil ice.

Construction Features.—The site selected for the location of the plant was a point on Dufferin Island, where the ground elevation was some 14 ft. to 15 ft. below the mean water level of the forebay of the Ontario Power Co., and the elevation of the rock formation which forms the base of the reservoir was discovered some 14 ft. below ground elevation— i. e., about the ideal position for foundations.

The site itself is part of the Niagara Falls Park system, and is heavily covered with vegetation, but accessible by road and by electric railway. The size of the plant, approximately 5,500 cu. yd. of concrete, suggested that a central mixing plant would be an economical arrangement, and the elevation of the approach suggested that material brought in on the electric railway could be dropped into bins and mixers without secondary handling. By an understanding with the Victoria Parks Commission, it was agreed to limit the destruction of trees to an area 75 ft. around the limits of the proposed works, and the problem of the contractor was to utilize this ground to such advantage as to permit him to carry on the works expeditiously without any further destruction of vegetation.

The contractors bidding on the work saw no particular difficulty in the arrangement, except that if the electric railway was not utilized there might be some embarrassment experienced, owing to the park superintendent limiting loading capacity of trucks and vehicles for the purpose of preserving and maintaining, during the tourist season, the river boulevard property, which also serves as approach to the plant.

The site naturally suggested a gravity plant with the high-duty pumps arranged so as to draw directly from the level of the clear-water reservoirs.

Mixing Chemicals.—The use of the hydraulic pump was considered and approved for the purpose of mixing chemicals, water being admitted from the upper forebay to the rising well and controlled by a mechanism actuating through floats and controlling the hydraulic inlet valve. After passing over the hydraulic pump, the water passes through the usual type of sedimentation tank and flows directly on to the filters through ports controlled by sluice gates, the wash-water channel and troughs being utilized for both the admission of sedimented water and the withdrawal of wash water.

Pipe Gallery.—The first unusual feature is perhaps the pipe gallery, with its arrangement whereby a travelling crane can be installed, hung from the upper beams, for the purpose of erecting and handling the control parts and pipes. The use of victaulic couplings rather than the flanged connections was contemplated, and in my opinion, offers considerable advantage.

Sand Strainers for Underdrain Systems.—The second unusual feature is the sand strainers for the underdrain system. Instead of making use of any of a group of patented arrangements, either of sand valves or special grids, I have recommended the use of a cast iron cover over a concrete trough, with a simple design of manifold cast integrally with the cover. This in itself is not unknown, having been used at St. Catharines. The unusual feature is that instead of screwed or leaded joints I propose to use a tapered push joint for the radial 1½-in. or 2-in. pipes, and hold them in place with a concrete haunch along the base of the tank. The arrangement has several very important advantages. It is incapable of a leakage greater than that from any one of the openings, and it is incapable of breaking away from the main header, as has been the case in some of the screwed pipes or leaded joints. It also appears to be a most economical arrangement.

Chemical Storage.—The next feature of interest has to do with the storage of chemicals. The plant which I was designing was to be such that it could be operated by the existing personnel, with the occasional inclusion of ordinary labor for special purposes. For this reason, instead of using overhead storage and dry feed machines, as is most convenient and satisfactory in a lot of plants, I used a portion of the foundations for wet storage of a saturated solution and capable of receiving several cars of chemicals. The chemical is taken from the cars and discharged down a manhole to a lower bin, which is immersed in water. When the storage is first charged, a portion of the chute will be full of undissolved chemical and will remain so until the use of chemical will have dissolved out the portion supporting the overlying mass. It was my intention to pump the concentrated chemical to a solution feed machine actuating from a constant level, diluting the solution as the reactions intimated was advisable.

In addition to alum storage, I purposed having track-work suspended from the ceiling of the screen room, so that I could use drums of ferric chloride, either to supplement the alum or to displace it entirely during periods when the ferric chloride might be suggested as the more suitable chemical.

Arrangement of Screens.—In the screen room, while it is not an unusual feature, the arrangement is specially adapted to the removal of frazil ice, and the screens themselves are of the sloping rather than the vertical type, so that they can be elevated out of the water, should conditions be acute. After passing the screens, the water flows directly over the pump and through the settling tank, and then on to the filters. Instead of using earth on top of the settling tanks, I thought it advisable to insulate them with cork, or other suitable material. According to the estimates, the difference in cost was not prohibitive, and it had a great many advantages which determined our policy in the matter. The entire roof of the building is also insulated, to keep down condensation and to simplify heating problems.

In the pumping station we have venturi controls both on the inlet water and on the water going to the suction well for the pumps. These controls are primarily for the proper application of chemicals. They also actuate the mechanisms which regulate the opening of the hydraulic valves, maintaining constant differential levels.

Piping Layout in the Pumping Station.—The piping layout in the pumping station is somwhat unusual in that provision is made for testing any of the several units in use, without throwing the station or other units out of service. The units have both duplicate discharge and duplicate suction lines, as recommended and urged by the underwriters. A by-pass has been introduced, so as to relieve the discharge system into the suction well for testing purposes.

The arrangement for the supplying of power for the operation of the electrical pumps is rather unique, although not novel to this plant, in that it provides an inter-switching arrangement with four of the principal developing companies at Niagara Falls, and precludes the possibility of any shutdown of duration.

It was my intention, in connection with the service pumps, to have push-

button control on the electric circuits and a hydraulic or electric valve operating the discharge line; the whole arrangement both of the filter plant and of the pumping station being such that the operators had a minimum amount of manual labor, and such appliances accessible as would permit the keeping of the staff down to the irreducible minimum.

Financial Aspects of Municipal Water Works

Some Details That Make for Successful Operation

By C. A. McCLAIN
General Superintendent-Secretary, Water Board, Eugene, Ore.

AN essential foundation for the successful operation of a municipally owned utility is the proper attitude on the part of the citizens. They must be willing to adopt a charter so drawn as to admit of business-like conduct of the utilities without undue obstruction or hampering through formality and red-tape.

The Management.—The management should be in the hands of a commission stable in its organization, nonpartisan, independent in its action and separate from other departments of the city, whose members have no other city offices. They will thereby be free to make decisions and formulate policies for the best interests of the utilities and will be nonpartisan and uninfluenced by other city interests.

The management of the utility should be put on a sound and dignified business basis which will not give the citizens the impression that the utility is a plaything which may be used to meet the passing whims of various groups or organizations. The term of office of the members should be long enough to enable them to become really familiar with the problems involved and terms should so terminate as to bring one or at most two members on the board at the same time.

The Employees.—The financial status of any business whether a utility or a commercial enterprise is determined very largely by the organization or staff of employees. The same principles apply to this kind of organization as are effective in any other kind of business. They must be loyal, industrious and efficient, and their salaries should be as much as the same people would be paid anywhere else for doing the same kind of work. A city employee should not be expected to work for less than he could get elsewhere, and it is demoralizing for him to be required to apologize for his salary.

The service furnished by a municipal utility may be up to the standard of a privately owned utility if the ordinary rules of conducting such businesses are observed and if efficiency, initiative, loyalty and other desirable characteristics of employees are recognized and rewarded.

The Rates.—Rates should be as equitable as possible and should provide for the payment to the utility by the governing board of adequate rates for all service furnished for public uses, such as street flushing, sewer flushing, fire protection, street lighting and other service furnished for the general public. They should be sufficient for all legitimate requirements such as operation, maintenance, interest on bonds, sinking fund for retirement of same, an emergency fund, taxes if paid by the utility, and should also provide a substantial surplus for minor extensions for plant.

Taxation.—Municipally owned utilities are exempt from taxation in most states, although in some states a bookkeeping entry is required to show the status of the utility as if taxes were paid. Some utilities make a voluntary payment to the governing body of the city, while on other occasions the governing body exacts the equivalent of taxes or in some cases much more through its demands for free service. Practically all economists hold that municipal utilities should pay taxes the same as are paid by privately owned utilities, although some propose that all utilities be exempt because of the fact that the consumer must in all cases pay the tax.

If taxation is applied equally to all municipally owned utilities there may be no objection to this, although the legal requirement that all cities provide a sinking fund for the retirement of bonds in addition to all other requirements of operation and maintenance impose an additional burden on the municipal utilities which privately owned utilities do not have to carry and it would seem fair that the municipal utilities may be entitled to tax exemption because of this sinking fund requirement.

Financing New Developments.—In the case of new developments the capital required must of necessity be borrowed. The usual way of acquiring that capital is through the issuance of bonds. If these are general obligation bonds they usually carry a lower interest rate than that earned by securities on privately owned utilities although the sinking fund requirement mentioned above may entirely offset this advantage. In some states utility bonds are issued, that is, bonds secured by the utility itself, in which case the interest rate is about as high as that paid by privately owned utilities, and may even exceed that rate.

Securities Owned by Local Citizens.—The customer ownership plan which is coming into general use with privately owned utilities, is excellent, and it would be a decided advantage if the municipally owned utilities might avail themselves of this plan in the distribution of bonds directly to its own citizens. If this were possible the municipal utility could well afford to pay a higher interest rate than when its securities are owned by people not directly interested in the service. A substantial emergency fund should be provided, the size depending on the general type of utility and also on the individual utility as to its own hazards. It is not practicable to issue bonds for the construction of every small extension required for service and therefore it seems a good policy to provide for most of the small extensions and a fair percentage of the larger ones from earnings from the system after it is in operation. If this be done, the ultimate effect will be lower rates because of the reduced charges on account of being relieved of interest and sinking fund requirements. Corresponding rate reductions will in effect be a division of this surplus with the customer.

Long time budgeting is equivalent to long distance planning, and will keep the utility prepared to meet future demands and at the same time will enable it to appropriate to specific projects net income accruing from year to year as a result of operations. This can be done only through a constructive expansion program which must be carried out without interference.

Accounting.—Accounting is an extremely important phase of the management of the municipally owned utility and should be in the hands of a competent staff of accountants. Above all the commission and its manager should not fool themselves regarding the exact financial status of the utility. Although not required by the Oregon laws to do so, we believe that it is to the best interest of the utility to use the Uniform System of Accounts prescribed by the Public Service Commission.

No department can be any better than its personnel. Therefore, the commission should avail itself of the specialists available, in the conduct of its business and in the meeting of new problems incident to its expansion program. A few of these experts who are readily available and who can be of great value are auditors, consulting engineers, economists, financial authorities, geologists, lawyers, rate engineers and testing engineers. As occasion may arise for the knowledge of these specialists, their employment will be found one of the best investments the utility can make.

Acknowledgment. — The foregoing paper was presented at the recent municipal finance conference held at the University of Oregon, in cooperation with the League of Oregon Cities.

Testing Cast Iron Pipe

Apparatus Used and Methods Employed

By WILLIAM R. CONARD
Conard & Buzby, Burlington, N. J.

THE apparatus used for testing primarily consists of a hydraulic press; the machines for the physical testing of the metal; and the tools (caliper, gauges, hammer, etc.), which the inspector uses in connection with the visual examination of the pipe. The hydraulic press is a piece of apparatus which seals each end of the pipe, fills it with water, exhausts the air, and then by a pump acting usually through an accumulator raises the water pressure in the pipe to some specified amount. The other apparatus for physical testing of the metal usually consists of a tensile and transverse testing machines in which prepared pieces of iron, usually called test bars, are subjected to tensile and transverse stresses to determine strength and resiliency. The inspector's tools are his pick hammer, caliper for measuring the thickness of the metal and other dimensions, and gauges to further calibrate the different dimensions of the pipe and fittings.

Methods Employed.—After the pipes are cleaned and chipped and have undergone examination on the skids for dimensions, quality and appearance, they are put under hydraulic pressure and tested for strength and porosity. This is called in the specifications the "hydrostatic" test. There was a time in pipe making when this test was applied in an adequate manner to all sizes, as it still is in the case of larger pipe; the present practice in testing pipe 3 in. to 20 in., however, can only be termed adequate if the specified pressure applied for as short a time as 10 seconds is considered satisfactory. The reason why the pressure is held for such a short period of time is that the facilities for this part of the operation of producing pipe has in most cases been lost sight of in the endeavor to keep up to quantity production, and the necessary room and apparatus for the testing have not been provided for by the manufacturer to the same extent as have the facilities for the other manufacturing operations. On the importance which the purchaser attaches to the hydraulic test, would therefore depend the period of time to be specified that the pipes are to be held under pressure before they are accepted.

The apparatus for demonstrating the physical properties of the iron are usually the standard tensile and transverse testing machines fitted up to take the type of test piece which the specifications call for. The pieces for the tensile tests have approximately a 1 sq. in. cross sectional area, and for the transverse area 2 in. by 1 in. by 26 in.

The inspector's tools are primarily the pick hammer with which the pipes are tried for hardness and indications of and visible defects are explored; the caliper, which is used to measure the thickness of metal, and sometimes other dimensions, and gauges for checking dimensions. Other tools are measurement rules, steel tapes and minor special or odd tools used at intervals as a check.

Some purchasers require a check on the chemical components, and where this is required, the inspector has to have sufficient knowledge of irons to know something of the grades by visual examination, and to tell whether the proportions are right when the foundry analysis is made.

One of the most important functions of a proper testing of cast iron pipe is the inspector's visual examination of the individual pipe, and to be able to perform this part of his work properly requires that he have a good working knowledge of molding, pattern making, machine shop practice, chemistry and, most important of all, the causes and effect of the things that can and do happen in the manufacture of the pipe. Also, and of considerable importance, a knowledge of the principles of engineering as applied to the uses to which the pipe are to be put. All of these, together with good common sense and sound judgment, enables the inspector when he examines a pipe or special to quickly determine the suitability of that particular pipe or special for the use for which it is intended.

Other duties connected with the inspection or testing are for the inspector to witness the tension and transverse tests, to determine the general physical properties of the iron, maintaining a check on the producing the test pieces for these tests as well as the chemical analysis, and to maintain supervision over the coating as well as the weighing. Many purchasers also keep the inspector informed as to their requirements on delivery so that he being directly on the ground sees that these requirements are adhered to.

One of the last tests of pipe before loading for shipment is to weigh the individual pipe or casting to see that it comes within the limits for its size and class; if it is too light, it is either placed in a lighter class or put among the culls, and if too heavy it is either marked down to the top limit, placed with a heavier class, put in the culls, or if too far out of the way it may be scrapped.

Summary.—It is difficult to describe by written word the details of the testing of cast iron pipe, and to describe the methods used, for there are as many as seventy odd things that may make a pipe unfit for use, and therefore the individual visual examination is a most important part of the testing, and much depends on the extent of the training and the experience of the inspector, and his attitude toward his work. If he has had the training, is interested in what he is doing and why he is doing it, and assumes an unprejudiced attitude to both the material and those producing it, and also is willing to place himself in the position of trying to learn something each day, the purchaser who is having the material tested by such an inspector can usually rest easy and feel pretty well assured that his interests are being properly looked after. It is to be conceded that unless the work of inspection of pipe and castings is honestly and intelligently performed that the purchaser is spending money uselessly.

Cost Accounting for Sewage Works

The System of Urbana-Champaign Sanitary District

By GUS H. RADEBAUGH
Manager, Urbana-Champaign (Illinois) Sanitary District

RECORDS of costs of operation of sewage treatment works are of vital importance, in my opinion, with regard to the successful future of the subject in which we are so much interested.

It is not my desire in this short paper to present methods of cost accounting than can be used and adopted in the management of all treatment works. I do appreciate, however, that the engineering profession and the industries associated with this problem will be penalized by a public which is desirous of clean streams, better health and a keener respect for the great out-of-doors, if this group and similar organizations neglect the importance of a standardized national code of cost accounting for the construction and operation of sewage treatment works.

It is my opinion that community progress comes only to those municipalities which are fortunate enough to accept correct and economical design of public works, and which have public leaders who believe in and see to the intelligent expenditures of public monies. This and similar associations can do much to encourage and assist in establishing correct standards for our community leaders to follow.

Many of the citizens of the State of Illinois have awakened to their individual responsibility with relation to the pollution and destruction of the state's beautiful rivers, and are accepting the challenge of civilization by proper disposal of sewage and industrial wastes. Illinois has 22 sanitary districts organized under the Law of 1917 and 2 districts organized under special acts, the

Chicago and North Shore Districts. It is established that 135 cities and towns in the state are recognizing in some manner the importance of treating their waste.

The Urbana—Champaign District.—The Urbana and Champaign Sanitary District, organized May 24, 1921, was the fifth municipality in the state to take advantage of the Law of 1917. This district consists of a rectangular area with a maximum width of 2.5 miles and a length of 4.0 miles. The total area within the Sanitary District is 5456 acres or 8.53 square miles. The total population is now 38,540. The density of population for the district in 1930 is estimated at 6.4 per acre; by 1960 this may increase to 12.8 per acre. The present assessed valuation is $27,150,053. A $500,000 bond issue was voted Nov. 28, 1922. The total sewage treated the past four years is approximately 5,346,000,000 gal. an average of 1,336,525,000 gals. per year, or 3.66 million gallons per day.

A complete report covering operation and management of the district's affairs has been published annually, giving to the tax payers a financial history of the operation of their project. A yearly audit is made of the income and expenditures by a public accountant.

Essentials of Cost Accounting system.—In designing the cost accounting system used by this district several standards were established as essentials in maintaining an accurate record. These essentials were:

1—Any system used should be substantiated by the budget method of financial control.

2—The system used should make possible without excess labor a monthly operating balance sheet.

3—All expenditures should be properly charged to accounts as established by the tax levy ordinance.

4—The tax levy ordinance should be divided into specific accounts and amounts—thus

B-2 Employee's wages, $00.00.
B-3 Power and coal, $00.00.
B-4 Water, $00.00.
B-8 Grounds, $00.00.

5—Voucher checks must be signed by two officers of the Board and the Treasurer.

6—No account should be paid unless an itemized invoice is issued to the District covering the item of expense.

7—A yearly certificate of audit must be received by the Board from a public accountant.

With the above essential as the guide, the following is the adopted accounting program:

The Accounting Program.—The Treasurer of the District, under $50,000 bond, receives the monies collected from the levy by the County Treasurer and deposits same in the District's depository. The Treasurer makes a monthly report to the trustees of receipts and expenditures.

The manager receives the invoices for payment, arranging them into the proper accounts as established by the tax levy. They are then presented to the board at a regular meeting for approval or rejection. When the approval is made and the authorization is made a part of the minutes of the board meeting, a voucher check is drawn in favor of the invoice, the number of the check being entered on the invoice, it then being filed for audit. The check is signed by the President and Clerk of the Board and by the Treasurer. The Treasurer makes the entry in a distributional ledger. The manager enters the paid accounts under the proper distribution. The manager also presents to the Board a monthly appropriation analysis or budget control sheet, which shows at a glance the working balance of the various accounts, expenditures this month, expenditures to date, appropriation unexpended, total account balances and the bank balances for the month. This monthly appropriation analysis has been found to be of paramount importance in the proper control of all expenditures. The accounts of this district have the following headings:

	For Interest and Bonded Indebtedness	
A-1	Interest due and payable June 1, 1929	$00.00
A-2	Interest due and payable Dec. 1, 1929	$00.00
A-3	Principal payment due and payable Dec. 1, 1929	$00.00
	For Other Corporate Purposes	
B- 1	Salary of Ofc. & Atty. Fees	$00.00
B- 2	Employee's Wages	00.00
B- 3	Electric Power & Coal	00.00
B- 4	Water	00.00
B- 5	Repairs on Equipment	00.00
B- 6	Supplies & New Equip.	00.00
B- 7	Lab. & Ofc. Exp.	00.00
B- 8	Ground Maintenance	00.00
B- 9	Secondary Sett. Tank	00.00
B-10	Contingencies	00.00

Cost Data.—The district published reports show the following cost data:

Costs Per Capita

	1925-26	1926-27	1927-28	1928-29
Operation	$0.42	$0.48	$0.35	$0.38
Total	1.74	1.62	1.54	1.53

These figures represent all expenditures passed for payment by the Board of Trustees such as bond interest, bond retirement, new construction, engineering fees, legal costs, plant operation labor, etc., in fact every expenditure incurred by the district.

Conclusions.—The general public demands correct and standardized cost accounting for sewage treatment works.

In the opinion of many engineers cost comparison of works operation is at the present time difficult due to the varieties of interpretation of operation costs.

The strongest force tending to stimulate construction of sewage treatment works is the intelligent and honest management of those already in operation.

In my opinion the Izaak Walton League of America and the American Public Health Association have done more to prepare the public for the acceptance of correct sanitation than all other agencies combined.

With the above conclusions as my forerunner, I respectfully present to this convention this recommendation:

"That this organization recommend to the officials of the Federation of Sewage Works Associations that a national committee be developed to standardize a national code of cost accounting adaptable for sewage treatment works operation."

Acknowledgment.—The above is a paper presented June 21 at second annual meeting of the Central States Sewage Works Association, and printed in the July Sewage Works Journal.

State Sanitary Engineers Hold Phenol Conference

W. L. Stevenson, chief engineer of the Pennsylvania Department of Health, and E. S. Tisdale, chief engineer of the West Virginia Department of Health, met Ohio's chief engineer at East Liverpool, Ohio, July 9, on an important conference following which several joint inspections were made, "Ohio Health News" states.

The city of East Liverpool has provided new devices which are in the experimental stage and with which it is hoped to demonstrate the feasibility of minimizing, if not eliminating, bad tastes in Ohio River water resulting from accidental discharges of phenolic materials from by-product coke and other works where such wastes are being treated. This effort on the part of East Liverpool is a follow-up of work done in cooperation with the health department engineers of the other states in the Ohio River interstate stream conservation agreement. Practically all by-product coke works in the Ohio River drainage area have provided complete treatment devices for eliminating phenol, these devices being of varying types. However, it has been recognized that occasionally there may be accidents resulting in spills of the wastes for a few hours, which might occur a few times during the year.

In order to cope with this situation studies have been under way, chiefly at the Ohio Department of Health laboratories, in the way of research upon ways and means to combat the phenol at the water purification plants. One of the processes, demonstrated at the East Liverpool water purification plant, consists of superchlorination with chlorine gas and dechlorination with sulphur dioxide gas. The meeting at East Liverpool perfected notification arrangements whereby prompt notice would be available to the East Liverpool chemist and others downstream so that steps could be taken in the effort to eliminate the phenolic tastes from spills. The East Liverpool meeting was also attended by the district engineer of the Pennsylvania Health Department located at Pittsburgh. City officials present were: service director, A. W. Moore; water works clerk, F. K. Robinson and city chemist, T. H. Larkins.

Testing Large Meters in the Field

Methods with Freeman Nozzles and with Previously Calibrated Meters

By R. E. FERGUSON

Assistant Superintendent, Hersey Manufacturing Co., South Boston, Mass.

TESTING by the use of the Freeman nozzle is mostly confined to laboratories of insurance companies, pump manufacturing companies and universities. If one has an unlimited flow of water, there are many advantages of the nozzle test over the tank and scale tests. For instance, the range of flow is easily controlled, the duration of the test is not confined to a few hundred cubic feet, and if the tests are conducted in a careful manner, they are very accurate.

Testing with Freeman Nozzle.—Figure 1 shows an 8 in. meter in a nozzle-testing machine at the Lowell Water Department, Lowell, Mass. As this is a 6 in. machine, and we wanted to test an 8 in. meter, we used on the inlet end of the supply a 6 in. x 8 in. adaptor and about 12 ft. of 8 in. straight pipe. On the outlet end of the meter, we used an 8 in. x 6 in. adaptor, the control valves and about 8 ft. of straight 6 in. pipe, with the pizometer and nozzle on the end. This straight piece of pipe ahead of the pizometer was sufficient to straighten out all the eddies and current induced by the change in pipe sizes. The pressure in the pizometer was regulated by the three valves, 6 in., 2 in. and 1 in. In running a test, we opened the larger valve until the pressure was within about ½ lb. of that desired, and then we used the small valve for the finer adjustments. With this small valve, we could also control any slight fluctuation of the pressure. During the test, the pressure was checked in two ways. First, by the spring gauge which was attached to the pizometer, and secondly, by the mercury column which was also attached to the pizometer, through the same connections as the spring gauge. The spring gauge is graduated in 1/10 of a pound, and the mercury column in 1/5 of a pound. On this test we used the 1 in. and 4 in. nozzles. The rates varied from 75 g.p.m. to 2,880 g.p.m. The pressure at the nozzle used was from a minimum of 6 lb. to a maximum of 29 lb. The pressure on the inlet side of the supply line was 70 lb.

Figure 2 shows a close-up of the meter and a mercury column to check the loss of pressure across the meter and the method of attaching the mercury column to the meter. It also gives a better view of the flow regulating valves. I might also add that on the inlet end of the supply pipe, an air release valve was installed. The water was supplied through about 40 ft. of 6 in. pipe to the test machine and was a take-off from a 24 in. main. The water was discharged into the pump well so there was no waste of water.

Method with Previously Calibrated Meters.—Figure 3 shows an installation of a 4 in. compound with a 4 in. bypass and the proper valves installed so that the meter repair man can test and repair the meter without interference with the consumer's water supply.

In some cities, these bypasses are the same size as the meter. That is to say, if there is a 4 in. supply line, the bypass around the meter is a 4 in. This bypass flow is controlled with a gate valve which is locked tight with a chain and padlock, the only key to which is held by the water department, and in some cases, seals are used. In this picture, you can see the test meter attached direct to the meter with a 2½ in. hose. In some cases, a test tee is installed in the line between the outlet end of the meter and the gate valve. This installation, as you can see, has a 2 in. gate valve attached to the meter below the hose connections, the advantage of this being that when making a test, the valve on the inlet side of the meter does not have to be shut to make test connections. If it is necessary to shut down the valve to make test connections, the incrustation from the side of the valve may be broken and lodged in the meter stopping same. This would necessitate opening the meter and cleaning it out before conducting a test, which in the case of a disputed bill would make the test almost worthless.

The illustration also shows the meters which we have used a good many years for making this test—a 3 in. velocity meter for the large flows, and a ¾ in. disc meter for the small flows. These two meters are connected to the meter to be tested with a 2½ in. high pressure hose, the flows through the 3 in. meter being controlled by a 3 in. quick-closing valve, and the flows through the small meter being controlled by the ¾ in. angle valve on the side of the 3 in. meter to which is attached the ¾ in. When using the small meter, the 3 in. gate is closed, and vice versa. The 3 in. valve is a quick-closing valve which enables the tester to close the meter more accurately than by a screw stem valve. The rate of flow is controlled by only partially opening the quick-opening valve, and, with a little experience, the tester can gauge his flows very close to the desired rates. Of course, he checks his flows with a stop-watch. In some cities, different sized orifices are used to control the rate of flow, but of course, as the pres-

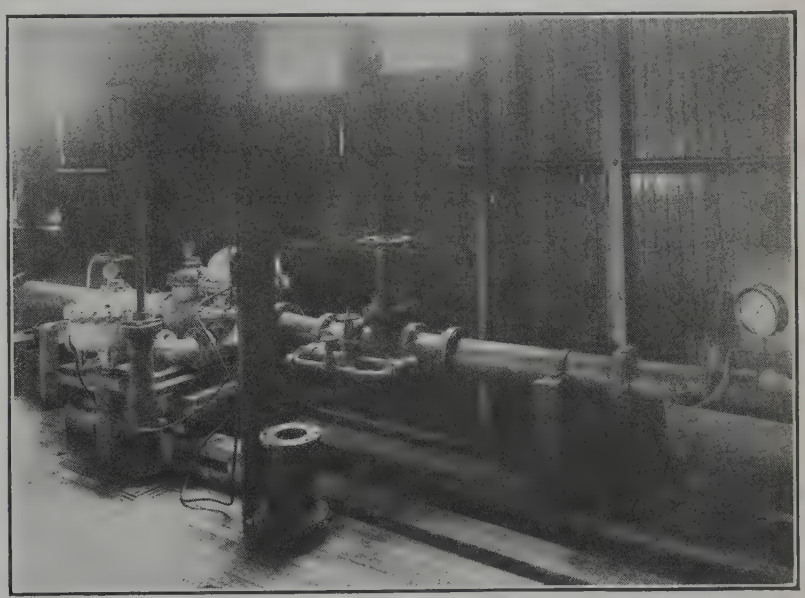

Fig. 1—Installation of 8 In. Meter in the Freeman Nozzle Testing Machine

sure varies in different localities, so will the rate of flow.

In some cities, where they test their large meters at least once a year, the engineer in charge runs what he calls an up and down test. This is run by opening and closing the controlling valve, slowly, during the test so that during the test the flow will vary from the minimum to the maximum rate of the test meter. This almost invariably not only covers the average rate of consumption, but the small night flow and the peak load.

In testing large meters with this apparatus and with from 15-20 ft. of hose under 50 lb. pressure, one is able to test flows as large as from 450-500 g.p.m., which in all ordinary cases is ample. Of course, for the low flows, for which the ¾ in. or 1 in. meter is used, one is able to test the minimum rate at which the meter to be tested is guaranteed.

Why Velocity Meter Is Used.—There are two reasons for using the velocity meter. The loss of pressure is very low at high rates, and at the same time the velocity meter will pass sand and small particles of dirt without interfering with the registration. There is also a strainer on the bottom of the measuring chamber that will stop foreign matter which is large enough to retard registration. I am not inferring that most water departments have more or less sand in the water, but in running these tests, especially on flows larger than the average consumption, if there is any accumulation of sand or dirt in the pipes at all, it will be drawn through the test meter. Of course, this is not true of the smaller rates of flow through the ¾ in. disc meter.

In testing any type of compound meter, it has been our practice to test

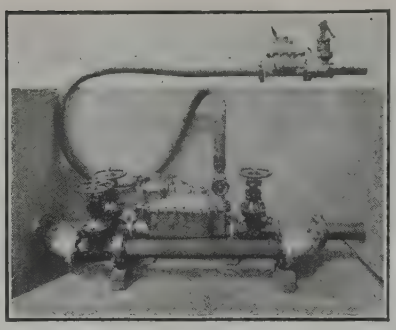

Fig. 3—Installation of 4-in. Compound with Bypass and Test Meters Attached

the smaller flow first, so that if there is any error in the meter it can be segregated. If on testing the bypass meter, it is found to be in error, this error is corrected before running flows that are registered on both the main line and bypass meters.

We have no specified rates of flow at which we test meters in the field, as we allow the superintendent to designate the test rate he wishes us to run, because in a good many cases, the superintendent has a very good idea of the average rate of consumption through the meter. Before making these tests, the test meter is tested in our testing department and the test card attached to the meter before it is shipped.

Setting Meters.—Before closing, I would like to say a few words on a subject not of testing, but which is very closely related to it, i. e., pits in which the meters are set. I have seen meters set in pits so small that the top of the pit had to be removed before one could hook up the test apparatus. I have seen a meter set with a 3 in. gas pipe crossing over the top at right angles and clearing the meter by not over 6 in. In a number of cases, meters are set in pits so narrow that a man could not remove the meter bolts except with a socket wrench or a hammer and chisel. Of course, this is unavoidable in a good many cases owing to other underground conditions, but if the man in charge of building meter pits kept in mind the fact that the meter might eventually require repairs, and that in all probability the work would be done in the pit, I believe we would find the pits larger. If the meter cannot be set without the cover being close to the top, dig the pit 18 in. or 2 ft. below the bottom of the meter, and if possible, have a drain in the pit. This will not only help the repair man, but also will assist in keeping the registers cleaner.

Acknowledgment.—The above is an abstract of a paper presented Sept. 18 at the 48th annual convention of the New England Water Works Association.

Field Mice Attack Trees on Water Shed

An effective campaign against the field mice, which have been attacking a large number of the 40,000 to 50,000 Scotch pine trees planted three years ago in the 40 acres of forestation for the protection of the watershed at Lock Raven, has been started by Water Engineer Edward G. Rost of Baltimore, Md.

The mice have been attacking the trees in the fall and winter months after the vegetation starts to die and they can find nothing else upon which to feed.

The damage to the trees was discovered after the needles on the trees had turned brown and there was other evidences of decay. While the attack has been made chiefly upon the young trees the mice have not overlooked some of the older and taller ones.

Experts from the United States Department of Agriculture were called in consultation and after an examination stated they believed the trees were victims of spittle bugs.

A later examination by Mr. Rost disclosed holes at the base of the trees. Upon removing some of the soft dirt with his hands Mr. Rost found the bark at the roots had been eaten away and this led him to believe the destruction was due to mice. The bark on the trunk of the trees also had been eaten in places by the rodents.

After the setting of 100 wire traps failed to render the desired effect Mr. Rost held a conference with F. N. Jarvis, in charge of the Eastern Rodent Control District of the Biological Survey of the Department of Agriculture, and it was decided to place poisoned oats in the runways on the watershed near the trees for the purpose of exterminating the mice. It is known the rodents will eat the oats in preference to any form of vegetation and it is hoped by this means that the offenders will soon be exterminated.

Two-Main System of Water Distribution

Experiences in Chicago Show System More Economical Than the Single Main System

By J. B. EDDY
Engineer, Water Pipe Extension, City of Chicago, Ill.

THE city of Chicago has adopted a definite policy regarding the use of the two-main system of water distribution. While not used exclusively for all new installations, its advantages are kept in mind and whenever the benefits to be derived warrant it, the two-main system is used. No hard and fast rules have been adopted, each installation being considered on its own merits; however, in car line streets, wide boulevards, newly widened traffic arteries and in streets 80 ft. wide, with fronting lots, two mains are laid. The first street in which two mains were laid in place of one was a "downtown" business street.

Replacing Old Main with Two New Ones.—During the years from 1907 to 1912 inclusive, pitometer surveys were in progress in and adjacent to the central commercial and business section (known as the Loop district) of Chicago. Elimination of underground leakage was a part of this work, special attention being given to streets about to be paved. In this section of the city many services had been abandoned where large buildings occupying a number of lots replaced a number of smaller buildings. These abandoned service pipes, of lead, were often battered shut where cut near the curb, many opened up from the effect of pressure, and sand washing quickly enlarged the opening. The result was usually an underground unobserved leak—growing as time went on until many were discharging the full capacity of the service. This section of Chicago has a sandy subsoil over which usually were placed, as the street grades were raised, cinders or other fill, making easy the escape to the sewer of underground water. Under such conditions it was necessary that the water system be thoroughly overhauled prior to repaving.

The 6-in. main in Randolph St., La Salle St. to State St. (three blocks), was tested for underground leakage in 1910 previous to repaving. The tests were made at night because of the density of daylight traffic and the inconvenience to the public which would result from a shutoff made during the daytime. Underground leakage amounting to approximately 200,000 g.p.d. was measured.

This 6-in. pipe was laid about 1855 as a part of the original cast iron system. Later, filling placed in this street gave the pipe a cover of about 10 ft. Street car tracks were laid over the 6-in. pipe, the location of the main at State and Randolph Sts. being about 1 ft. south of the center line of the street. After a comprehensive study had been made it was decided to replace the old 6-in. with two new mains, one 12-in. to extend from State St. to La Salle St. adjacent to the north curb, and one 8-in. to be laid adjacent to the south curb in blocks requiring services.

Considerations in Installing Two Mains.—The reasons for this decision were as follows:

1. It would be very costly to locate and stop the underground leakage.
2. Traffic would have to be diverted to other streets while repairs were being made, which would greatly inconvenience the business houses on this street and the public generally.
3. Additional supply, both for fire and commercial use, was necessary.
4. Service pipe stubs not in use could be abandoned.
5. Live services could be retapped to the new mains, thus eliminating all piping beneath the car tracks (except at cross streets), making less service pipe to be maintained and reducing the electrolysis, known to be active in this street.
6. Future large service pipes for fire and commercial use could be installed at greatly reduced cost.
7. The mains near the curb lines could be maintained with little inconvenience to the public and at less cost than the old main beneath the street car tracks.
8. No main would be laid on the south side of the street between La Salle St. and Clark St. because of no service requirement. Fire protection in this block would be furnished from the 12-in. main.

The factors given greatest weight in the conclusion reached were:

1. Public convenience.
2. Future maintenance cost.
3. Additional supply.
4. Elimination of underground leakage.
5. Electrolysis mitigation.

The 12-in. and 8-in. mains were installed in 1910 and this marked the beginning of the use of the two-main system in Chicago.

Since this work was done, similar investigations have been made in other loop streets until now many of the streets in the downtown section have two mains.

Water mains in the loop are not laid in the sidewalk space because this space is usually occupied for storage and other purposes. Variations of the two-main system exist, mains being laid in alleys, only one main being laid where service requirements are such as to make two mains unnecessary. In some streets having street car tracks the old

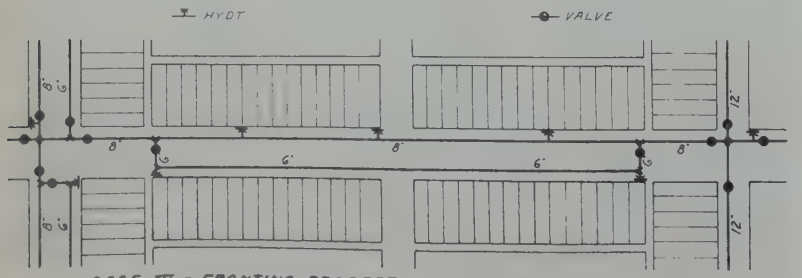
Plan for Mains for Fronting Property on One Side of Street and Parts of Other Side of Block



Plan for Mains for Fronting Property at One End of Each Block, Siding Property at Other End

main was in such a location as to be readily accessible. In such streets a second main was laid near the opposite curb, the old main overhauled, and the services in use to the opposite side of the street reconnected to the new main. All service pipe stubs were shut off at the main.

Laying Mains in Michigan Blvd.—In 1922 the roadway of Michigan Blvd., from Roosevelt Rd. to 33rd St., was widened about 7 ft. on either side and paved. The old 6-in. water main was located about 10 ft. west of the center line of this 100-ft. street, and had given much trouble when repairs were made and when large services had to be installed due to a change from residential to commercial occupation because of the danger to workmen and the inconvenience to motorists. Additional capacity was needed in this street.

It was decided to abandon the old 6-in. and install two 8-in. mains, one on either side of the boulevard. Trenches were excavated by digging machines excepting street intersections, which dug by hand. Each main was laid as near the new curb line as possible. It was necessary to cut the sidewalk for 10,560 ft. of this improvement. In the remainder there was a 7-ft. parking space in which the pipe was laid. The amount of pipe laid was 23,720 ft. and the time required for the work was about four weeks.

Many old service pipe stubs were abandoned.

All live services were reconnected. The cost of this work was $2.95 per foot, the material costing $1.60 per foot.

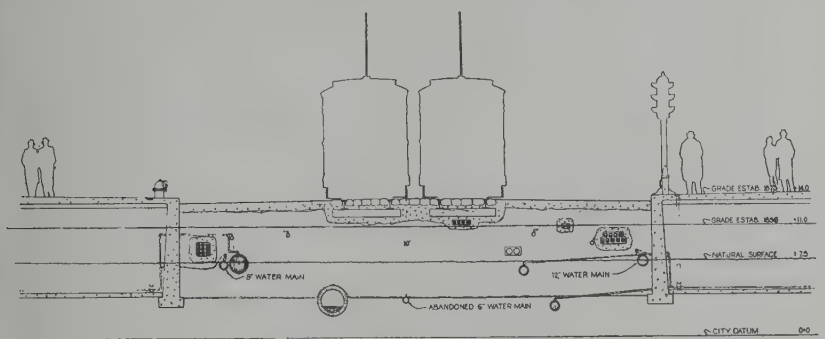
Factors to Be Considered.—Whether or not the two-main system is used in Chicago is not always determined by first cost. It is installed in business streets, car line streets and boulevards because it has been shown by experience that after installation in such streets the two-main system causes less inconvenience to the public and is less costly to maintain than one main with long services.

In all residence streets of less than 80 ft. in width, except state roads, an estimate of cost is made to determine which system shall be installed. However, there are many factors which should be considered in addition to first cost when deciding whether or not to use two mains.

Usually the street pavement is laid a very short time after the water main and service stubs have been installed, and for this reason pressure is being exerted to have all excavated material other than sand or gravel hauled away and sand used for backfill, so that the pavement can be laid immediately following the completion of underground utility work. This provision has been enforced a number of times within the past few years and the cost of hauling away excavated material and hauling in sand, plus the cost of one main and long services, greatly exceeds the cost of two mains back of the curb lines.

Of course, it is necessary that traffic arteries be out of service for repaving as short a time as possible, and sand backfill aids greatly in cutting down the time of making the improvement and insures that the new pavement will not settle over newly made trenches. It does not assure that the new pavement will not be cut to make repairs, and therefore when no main has previously been laid it is better to lay two mains inside the curb lines, which makes the sand backfill unnecessary and places the pipes where they are readily tapped or repaired without going into the pavement. Also, mains and services need not be laid, except crossings, until water again the weak spot has been the wiped joint.

Two-Main Systems for Streets Paved by State.—The state of Illinois requires the two-main system where streets and roads are paved by the state. Standards are provided in the state specifications for arrangement of pipes, sewers and conduits for rights-of-way varying from 50 to 100 ft., two of which are shown. Provision is made that all pipes, sewers, and poles shall be placed outside of a 40-ft. strip which centers on the center line of the right-of-way. The conduits are located so that they clear a 20-ft. pavement but lie under a 40-ft. pavement.



Cross Section of Randolph St. Showing Abandoned 6-In. Main with Existing 12-In. and 8-In. Mains and Utilities

for service and fire protection is actually needed. Streets have been treated in this manner in Chicago with satisfactory results, the paving in some cases having been down for five or six years before water was required in the street.

Causes of Leakage.—In connection with the overhauling of mains and services, prior to paving, it has been found that the lead service pipe is a greater source of underground leakage than the cast iron main. From 1916 to date, 966 service pipe leaks have been repaired which showed a measured leakage of 5,336,000 g.p.d. During the same period 429 main leaks have been repaired which gave a measured leakage of 3,590,000 g.p.d. The service pipe leaks are usually at the wiped joint either at the coupling to the tap or at the stopcock, more frequently at the former.

The point is that the number of wiped joints can be greatly reduced where two mains are installed because service pipes are laid only when and where required and not for every lot. Furthermore, where no trenches are dug crossing the sewer there is a greater possibility that the leakage will show up at the surface since trenches give easy access to the sewer.

In connection with maintenance work, 68,998 service pipe repairs have been made as compared with 41,459 main repairs from 1916 to date. No measurement of leakage has been made in connection with this work, but here

In a number of streets that were being repaved, it was found economical to abandon the old main and lay two new ones. The old main in each case was obsolescent, badly corroded by electrolysis, inaccessible, or it was known that the cost of digging it up to salavge would exceed the value of the pipe. Old mains, where accessible and in good physical condition, are always overhauled before a street is paved, leakage being located and stopped and abandoned services closed off at the main.

Variations of Two-Main Systems.—Many variations of the two-main system may be used. A street may have solid frontage on one side and partial frontage on the other, in which case the plans shown in the illustration may be used.

In some sections of Chicago the two-main system has been used almost exclusively.

Experience in Chicago with the two-main system has been most satisfactory and demonstrates that in the last analysis, this system is more economical under the conditions where used than would be the single main system. The saving in initial cost of service pipe, the lower maintenance cost, the additional capacity, the better fire protection, the reduction of electrolysis, all contribute to economy.

Filter Material for Sewage Trickling Filters

The American Society of Civil Engineers Committee on Filtering Materials for Water and Sewage Works, which has been investigating this subject for several years has a progress report in the September Proceedings of the Society. The following tentative conclusions are given on testing and selecting filter material for trickling filters:

(a) Material for filter media should be sound, hard pieces with all three dimensions as nearly the same as possible, clean and free from dust, screenings, and other fine material. It should be of as nearly uniform size as possible, and the material should not disintegrate under service conditions either by breaking into smaller pieces or by crumbling into fine material.

(b) In selecting the most suitable material for a given installation from the available sources of material, careful investigation of the several sources of material should be made, including geological inspections of quarries, a study of the facilities for obtaining, screening, and cleaning the desired size of material, and a laboratory analysis of samples selected from the several sources to determine the comparative merits of the several materials as to the probability of the breaking down of the materials under filter service conditions. For this laboratory analysis samples should be selected from the various ledges in the several quarries or from the several possible storage piles.

(c) The investigation of the Committee to date indicates that the sodium sulfate soundness test is the most indicative test for predetermining the disintegrating qualities of the proposed material. Other physical tests, including the determination of specific gravity, the absorption, and porosity, give useful information. Chemical analyses are of value in determining the effect of impurities, such as earthy materials, iron, and sulfur, and, in some cases, lime and magnesium. Micro-structural analyses made by properly qualified examiners may also be useful.

(d) Great care should be taken in obtaining the filter material from a selected source to insure a uniform grade and size, free from dirt and fine matter. There is evidence to indicate that improper screening for size and cleaning of filter material for many of the existing trickling filter installations has been of influence in the deterioration of the filter beds, perhaps more so than the matter of breaking down or disintegration of the individual pieces of filter materials. It appears that proper sizing and cleaning of filter material cannot be obtained without special arrangements for screening and rescreening and perhaps washing of the material either at the source or at the filter plant immediately before placing the material in the filter bed.

Water Works Management

Essentials in Successful Management of a Municipally-Owned Water Works System

By H. E. MOORE
Secretary, City Water Works, Dallas, Texas

FOR the purpose of discussion I shall refer only to the municipally-owned water works system, though in my opinion the holder of any privately-owned franchise of this nature should live up to the same high purpose or forfeit the privilege granted him. No corporation has the right to make a profit from any public necessity unless it honestly and squarely studies the needs of the community supporting it, and endeavors to fill adequately the purpose of a water supply, that is city building.

Three Factors of Community Growth.—The question of water supply has always been a vital factor in human history. No civilization has ever developed without at least an adequate supply of fairly pure water. The modern age was ushered in by the three big factors of community growth, demand for sanitation in its various phases, and industrial development. Fire-fighting facilities I would class in the item of community growth. Under the term "sanitation" we can include both the direct health factors and the more indirect items of aesthetic value such as street cleaning, parks with wading pools and landscaped grounds, and similar demands which any community now makes upon the water supply system. It is not at all difficult to realize that the person responsible for the management of a water works systems has demands upon his abilities and activities which require real consecration to the task at hand. Let me change one letter in the title of my subject and make it read, "The Problem of Water Works Management." This problem is to keep a broad outlook and constantly survey the market for the commodity he is dispensing; to plan for future needs due to growth; to keep his rate schedules intelligently adjusted to the shifting requirements from the super-industry of which his department is a part, building desirable, healthy cities for people and encouraging the industries which supply their need of a livelihood. The need for uniformity of supply, accurate records for the distribution system, an adequate distribution system, and a proper accounting system, are all more or less important parts of the major structure centering about one individual. The wise manager will solve these various needs by selecting competent heads for the different divisions, and then lean heavily upon them. Thus his mind is relieved of a multitude of details and left free to think and plan along broad constructive lines.

Water Department Vital Factor in Growth of Town.—The problem of management is to get a vision of the possibilities and organize the department with a view to placing it in the first rank of leadership for the town which it serves. A well-balanced population center under modern conditions of necessity requires more or less industry to be self-sufficient and thiving. The demand for plenty of pure water for domestic and sanitary uses at reasonable rates is logical and must be satisfied. Right here is the largest source of grey hairs for the manager of a municipally-owned water system. His actions are unfortunately often more or less circumscribed by the political influence of his customers. These customers are ever ready to exercise the voting power in an effort to force cheaper domestic rates, regardless of the economics involved in our rate schedules. The tendency to put water departments under separate boards fairly free from political influence is going to measurably improve this condition. We must be cautioned, however, that with more freedom of action comes greater obligation to use due business principles to keep the domestic end of the rate schedules where they fairly belong from an economic standpoint. Abuse of this feature, with more freedom from the undue influences, will discredit the idea and offset the progress made. An efficient and fairly operated water department under a non-political management will in a few years gain a hold on the minds of a community that no municipal storm can shake. The public always approves efficiency and just dealings in the end. We must admit that most of our troubles from this source are due to a more or less justifiable reaction of the public to our overbearing attitude in the past.

Water Supply a Fundamental Factor in Industrial Growth.—The three fundamental factors of industrial growth are: (1) Cheap and dependable fuel; (2) cheap power; (3) cheap and abundant supply of pure water.

Lying within the boundaries of our southwestern states is enough lignite coal to supply the present and future needs of great industries. It can be obtained very cheaply by any community in this section. Development of this asset has been started on a large scale. In Oklahoma and Arkansas coal fields are high grade steam coal available at reasonable cost. We have cheap fuel oil from our oil fields, and gas for industrial purposes is in extensive use with ample supply. Power and light companies have developed an adequate and dependable source of cheap power for our needs. Now let me ask how many cities or towns represented here have a vision of their water supply system as a vital factor for the necessary industrial growth? It is really the most important of the three named, and belongs to the citizens of the respective communities. As a stockholder in the municipality every resident is interested in this question. It is in this connection that the need for scientific study of the rate schedules in effect exists. The bookkeeping system should include a method to give monthly summary sheets showing a summary of consumption recorded. They should separate accounts into amount-consumed classifications. In addition it should be the function of some one trained in such matters to analyze them and from time to time investigate the idea of adjustment to more equitably distribute costs and make the department function as a civic asset industrially.

Public-Relations Man Needed.—To my mind every water department logically needs a commercial agent or public-relations man whose sole duty is to sell the citizens on their own asset and study just such questions as I am raising. Every large concern selling a public service has a large commercial department with trained employes endeavoring to keep the charges of the concern intelligently balanced to the conflicting demands for meeting all costs and developing more markets for the commodity they have to sell. Of course you can readily understand that in smaller cities all the needs I am enumerating will logically center in the manager himself. This fact emphasizes the importance of putting competent, properly-trained men in charge of the water departments of such places.

Let the thought I leave with you be a resolve to study our water departments with the view to making them fulfill the mission I have outlined. The welfare of a growing town or city is bound up with the proper functioning of its water-supply division on a sound business basis. It is good business for a city to encourage the location of industry sufficient to supply every breadwinner with a job. When factories are seeking locations they weigh carefully the present and probable cost of the water supply necessary to operate in any site under consideration. Specifically I know that the present rate in Dallas has been one of the stumbling blocks to the chamber of commerce program for industrial development. This defect exists generally in this section and should receive our most earnest thought. In my own department we are studying this particular point and trying to map out a forward-looking plan to be the vital factor in our city's growth that the water department can and should be. Due to past circumstances similar to those in the history of large cities especially, most large buildings and factories have their own water supply in Dallas. Now the reason for existence of water works systems is that collectively we can have greater convenience, more ample supply, and better quality, at lower cost than individually. With adequate supply of high quality it is the essence of wisdom to get this business all con-

nected to the one system. Through that increased business the industrial water rates can be lowered below the cost of any individual system and serve to aid rather than retard the proper expansion of the city. We all operate on a "service-at-cost" basis and serving large users means to us ability to better serve the community of which we are so important a part.

Well Water Supply

Details That Should Be Considered

By W. KIERSTAD, JR.
Consulting Engineer, Kansas City, Mo.

MECHANICAL equipment of all kinds has been vastly improved during recent years. Well pumps have not lagged behind the procession in the march of progress but have been steadily improved until now equipment is available for the most difficult well pumping problems with many, if not all, of the old operating hazards removed.

Higher efficiencies are attainable, better materials are available for all wearing parts, improved types of bearings are replacing the ones which have been used in the past, more accurate methods of machine work are being employed, better workmanship by mechanical methods replaces much but not all of old craftmen's handwork and improvement in the actual design of critical parts are all the fruits of years of experience and painstaking effort on the part of manufacturers and operators alike to perfect well pumping equipment.

There is a definite and praiseworthy tendency on the part of pump manufacturers to standardize articles which they manufacture in the minutest detail. Such practice results in economy of production, uniformity of product and the most extensive interchangeability of parts possible. Competition in turn brings the saving in cost back to the user of the machinery and the standardization of parts facilitates maintenance.

Conditions Must Be Analyzed.—Nature, on the other hand, cannot be so standardized. Each well project must be carried out and the wells pumped under conditions that by nature are likely to differ to a degree from conditions at any other well site. We find with all of the mechanical improvements and highly specialized machines that now, more than ever before, it is necessary to make a careful preliminary analysis of conditions under which the pumps are to operate if full benefit is to be derived from highly efficient pumps and from the experience of those who have designed, improved and operated them.

Disappointment is sure to follow the blind selection of well pumping equipment just as it would be the purchase of a Packard pleasure car to perform the services of a 5-ton truck of equal value. A pumping unit which suits certain conditions admirably may fall far below the standards set by some other type of pump when installed without giving due and careful consideration to the natural circumstances and limitations surrounding the installation.

Careful Studies Desirable.—Much valuable information as to the depth, thickness and extent of the water bearing formation, the quality of the water and probable yield can at times be obtained from geological reports and from existing wells. Such information should be received and regarded with caution, however, unless the ability of the field to furnish an unfailing supply in the desired quantities has been definitely proven. Domestic wells have frequently been reported by their enthusiastic owners to be "inexhaustible," but which quickly dried up when a well was sunk in the locality and used to furnish water for a public supply. A considerable amount of money may be well spent for investigation, borings and test wells before committing the expenditure of a much larger amount to any public well water supply project.

In the absence of adequate preliminary studies the physical characteristics of the ground through which the well is to be drilled will remain pretty much an unknown factor until drilling operations are far advanced or even completed. Soft caving ground may be encountered for which support must be provided. Strata of mineralized water may be passed through which have to be sealed off from the desired supply, boulders or non-uniform material may be encountered causing a crooked well or numerous other difficulties may arise which affect to an important degree the type of well to be constructed, drilling methods and equipment to be employed and at last the pumping machinery to be installed.

Underground velocities vary widely, depending upon the fineness of the water bearing formation. The velocity in turn has a material affect upon such well characteristics as yield, drawdown, sand content of the water pumped and also upon the number and spacing of the wells which a given district will support or which will be needed for an adequate supply.

Pumping Rate and Water Level.—This depth to water varies from a few feet to 1,500 ft. or more but the approximate depth to the desired water bearing stratum is generally a matter of common knowledge in any locality. The development of the first well or the test well will reveal accurately the level to which the ground water will naturally rise during different rates of pumping. These relations between pumping rate and water level may not remain the same over a period of years, particularly if ample provision is not made in the development process to prevent packing of sand and fine material around the strainer but it is largely upon this initial relation and knowledge of the methods of development that the water supply engineer must base his judgment, seasoned with experience in other localities, as to the best type and size of pumping unit.

Selection of Pumping Equipment.—It will always prove advantageous to defer the selection of pumping equipmene until after the well, or at least one well where a group is to be drilled, has been thoroughly developed. Unless this is done equipment unsuited to the conditions will probably be purchased and unnecessarily high operating costs will folow. There is a tendency on the part of many at first thought to select pumps for a higher head or of larger capacity than actually needed. Such a tendency is prompted by a desire to provide amply for extreme conditions of head and pumping rate, particularly in view of the low additional cost of larger pumps.

It would be far better, however, in endeavoring to provide an ample supply of water to drill two or more wells, pumping a nominal amount of water against a low head from each than to overtax a single well with a large sized and generally over-designed pumping unit. By so doing one often defeats his own purpose, causing the well to fail altogether by clogging on account of the high rates of flow or at least finding that the cost of pumping water is unreasonably high, due to low operating efficiency.

It is, furthermore, too frequently the practice to continue using a pump until because of wear and tear it fails to lift a sufficient quantity of water to meet the demands of the city and in such cases where an over-sized pump was originally installed the cost of power for operation at partial loads will be found to have increased to an excessively high figure before the much needed repairs are made.

Where a plunger pump is operated at a rate above the yielding capacity of the well so that it takes air the running of the pump becomes very uneven and the annoyance of rod breakage soon develops. Difficulties almost as undesirable, although not often so costly, are encountered in the operation of over-sized centrifugal or turbine pumps.

Pumps that are employed for pumping water supply wells may be roughly divided into four classes; deep well plunger pumps, deep well turbine pumps, air-lift pumps and centrifugal pumps of the vertical and horizontal types.

Each classification serves a definite field in the pumping industry, meeting particular requirements suited to it better than pumps of any of the other classifications.

Re-Sanding the Cincinnati Filters

By CLARENCE BAHLMAN
River Water Purification Supervisor, Cincinnati, O.

After 21 years' service, preparations are being made to re-sand the Cincinati filters.

As originally constructed, the filtering medium consisted of 8 in. of graded gravel and 30 in. of sand with an effective size of .34 mm and a uniformity coefficient of 1.60, and this sand averaged 1.1 per cent soluble in hot hydrochloric acid. The gravel and sand layers were separated by a perforated screen. In 1916 the screen was removed and an additional 6 in. of gravel was added. This brought the sand surface to within 24 in. of the top of the wash water gutter, as compared with 30 in. when the plant started operation in 1907.

Increased Size of Sand.—Examination of the sand every 2 or 3 years has indicated a gradual increase in size and incrustations. In 1928 the sand averaged .50 mm effective size, 1.29 uniformity coefficient, 50.8 per cent acid-soluble, and the distance from sand to gutter top had decreased to 15.5 in. In other words, the original 30 in. of sand had expanded, because of incrustations, to 38.5 in. The composition of the incrustations, as shown by analyses made by the state health department, was as follows:

	Per Cent
Silica	3.5
Iron oxide	4.7
Aluminum oxide	2.8
Manganese dioxide	1.7
Calcium carbonate	83.1
Magnesium carbonate	1.5
Organic, by difference	2.7
	100.0

No decreased filter efficiency has been observed as the sand became more coarse, but re-sanding is in order because of losing sand during the washing process, in which an 18 in. vertical rise per minute is used. Such loss, however, first noted about 3 years ago, has been confined entirely to the winter months. It seems that the greater density of the colder water has a more pronounced flotation effect.

Careful examination of the gravel layer, strainer system and underdrains has indicated that everything was in satisfactory condition, and a complete reconstruction of the filter beds is deemed unnecessary. It is not intended to disturb the gravel, nor remove all of the old sand.

The degree to which the old sand left in the filters will mix with the finer new material has been studied experimentally. One square foot areas, of a filter were blocked off and excavated to the gravel, and various depths of old and new sand were placed in these boxes, following by washing rates of from 18 to 24 in. per minute. It is evident that more or less mixing occurs, and that the new sand to be added must be somewhat finer than is finally desired in the re-sanded filters.

How Re-Sanding Will Be Done.—The plan decided upon is as follows: The reconstructed filter bed will consist of the present 14 in. of gravel and a 28 in. layer of sand, and the surface of the sand is to be 26 in. from the top of the wash water gutter. At least 12 in. and probably 16 in. or more of the sand bed will consist of new sand. The upper 12 in. of the finished filter, after washing, should show an effective size of from .34 to .38 mm. with a preference of not below .36 mm.

Because of long and efficient service obtained from the present filters it is deemed advisable to re-sand with material from the same source, namely Ohio River sand. Costs also strengthen this opinion. Fine Ohio River sand will cost us $1.60 per ton delivered, whereas sand from Youngstown and from Illinois has been quoted to us at $6.29 and $6.90 per ton delivered.

The effective size of Ohio River sand ranges from .24 to .27 mm. Laboratory studies have shown that by screening such material we are able to produce a sand which meets our requirements of .34 to .38 effective size, and 1.30 to 1.50 uniformity coefficient. The desired fraction was that retained between two screens having openings of 0.97 and 0.29 mm. respectively. Approximately 73 per cent of the crude sand was thus rendered fit for use, with a wastage of 8 per cent pebbles and 19 per cent silica dust. It was also found that the sand should be dried before screening, otherwise too much of the fine material was prevented from passing through the lower screen.

Drying and Screening Sand.—The grading of the crude sand therefore requires both drying and screening equipment. A rotary sand dryer heated with a kerosene burner was purchased, and after some alterations this was made to function satisfactorily. For screening the sand we have purchased a W. S. Tyler two-surface inclined electric vibrating screener. Two 4 ft. x 5 ft. screens are used, namely Tyler's No. 817 Ton Cap for the upper screen, and Tyler's 35 mesh, 0.013-in. opening steel screen for the lower surface. When inclined, the effective opening of these screens are equivalent to the opening of the laboratory screens which were used in horizontal position.

Preliminary trials with this apparatus produced sand averaging .345 mm. effective size and 1.51 uniformity coefficient; which seems to be just about what we require. Should screening on the large scale produce a somewhat finer or coarser product than anticipated, a change in the angle of screening will at least partially rectify the deviation. The measurements of the upper 12 in. of the new sand bed in the finished filter can also be controlled, within limits, by adding somewhat more or somewhat less than the 16 in. of new sand which it is expected will be needed in each filter. Thus two points of adjustment are available for correcting any differences between laboratory and actual results in practice.

That the re-sanding of the filters is an undertaking of some magnitude is apparent. To place 16 in. of new sand in the filters, assuming a wastage of 30 per cent in the screening process, will involve the drying and screening of 2,800 cu. yd. of sand, or about 3,800 tons. About the same amount of old sand must be removed from the filters and transported about 900 ft. to a waste pile. It is planned to do this with a hydraulic sand ejector and thence through a 4 in. pipe. A three-floor shed will be erected to house the drying and screening equipment. The sand will be unloaded from the hopper-bottom cars by means of a portable conveyor, which also will be used to elevate the sand to the dryer on the top deck of the shed. The dried sand will spill into the hopper of the screening machine on the second deck, and from here the 3 fractions of sand will be chuted into 1-ton industrial cars on the ground floor.

Acknowledgment.—The foregoing is a paper presented at the 8th annual Ohio Conference on Water Purification.

New York State Sewage Works Association to Meet at Schenectady

The fall meeting of the New York State Sewage Works Association will be held Oct. 19 at the Hotel Van Curler, Schenectady, N. Y. The program follows:

9:00 A. M.—Registration.
9:30 A. M.—Short description of Schenectady Sewage Works and General Electric Co. Industrial Waste Disposal Plant—Morris M. Cohn.
10:00 A. M.—Inspection trip to described plants.
12:00 Noon—Meeting of Executive Committee.
12:30 P. M.—Luncheon—Address of Welcome—Mayor Henry C. Fagal.
2:00 P. M.—Business Session.
3:00 P. M.—Technical Session (Papers, Discussions) "Present Status of Sewage Treatment in New York State"—C. A. Holmquist.
3:40 P. M.—"The Treatment of Milk Wastes and Whey"—Prof. C. L. Walker.
4:20 P. M.—"The Relation of Designing Engineer to Plant Operator"—H. B. Cleveland.
5:00 P. M.—"The Problem of Interception and Treatment of Buffalo's Sewage"—C. L. Howell.
6:00 P. M.—Dinner.
7:15 P. M.—Round-Table Discussion on Sewage Works Problems.
9:00 P. M.—Candle-light Dancing—Hotel Van Curler.

Round-Table Discussion Topics

Is Imhoff sludge saleable?
What are your odor problems?
Have you a rat menace at your plant?
What are you doing to awaken local interest in your plant?
Have you found a paint to withstand plant conditions?
How do you control your filter flies?
Are there any questions on the operation of the plants you have inspected at Schenectady?
What phases of plant operation need research?
What should this association do to sponsor sanitary engineering courses in colleges of the state?
What do you think of licensing operators?

Service Installation at Detroit, Mich.

By L. J. MONTGOMERY
Principal Water Permit Clerk, Department of Water Supply, Detroit, Mich.

The permit bureau has charge of issuing all permits for the installation of service connections and meters. As the work connected with the installation of water services and meters is an important part of building operations, stringent regulations have been adopted by the board of water commissioners to govern plumbers and plumbing, which are altered from time to time to meet changing conditions.

All master plumbers doing work in connection with the department must have a license both from the department of health and the department of water supply of Detroit, to secure which the plumbers must pass an examination in the art of the plumbing craft. This examination is conducted by the board of examiners of plumbers at stated intervals in the office of the board of health. After the plumber has passed this examination and presents his board of health license, the department of water supply issues its license, for which there is an annual fee of three dollars.

Procedure for Securing Service Installation Permit.—In applying for service installation the plumber is required to fill in a blank form, giving the street name, side of street, between streets, lot number, whether to supply a new or old building, owner's name and address. This he takes to our engineering department to check for main assessment and to secure location of main, size and width of street. When the permit is issued the plumber is given a stake bearing the number of permit. He is required to set this stake just inside of walk at the point where he wishes this department to enter with the service. The permit is then taken to the numbering department, city engineer's office and a house number is secured for the lot which receives the service. A typewritten order, which is a copy of the application, is then sent to the central storage yard and in due time the work is performed by the service installation department. At the time this is done the plumber's work from the house to the lot line is inspected to see that it compiles with the board's regulations as to depth, kind of pipe, etc. Should a delinquency exist, the plumber is notified that it must be corrected before further permits will be issued him. Should the Board desire, his license can be temporarily or permanently suspended.

The minimum size service pipe allowed is that of a ¾ in. This has been found of sufficient capacity to furnish a single house, two-flat, store and flat with tank closets, an adequate supply of water. Four-family flats must have at least a 1-in. service. Large apartments, commercial and industrial properties are allowed any size connection necessary for their supply. All service pipes must be of lead or cast-iron.

When application is made for a new tap the property to be served is checked in our register of connections and if any old connections are found to enter the property they must be removed at the street main. A charge of $20 is made for each old tap removed. When a new tap has been made and service installed this Bureau is notified by the service installation department, which furnishes the location of the stop-box controlling the service. This location, together with size of tap, date of issue of permit, plumber's name and permit number are recorded in ledgers used for this purpose. These ledgers carry a plat of all streets, lot numbers and the feet frontage of each lot. As the plumbers make application for new services these are compared with the records already existing, which serves as a check on the plumbers' information as to the correctness of the property's description to be served. This bureau records a list of all master plumbers, together with their addresses, telephone numbers, etc., so that they can be easily communicated with and notified of any new regulations enacted or any changes made in existing ones.

A record of all paved streets is maintained, giving age of pavement, this being necessary in order to make the charge for pavement cuts, as required by the city charter. A typewritten form, carrying all information on the application for new service, is furnished the rate bureau and these are filed in numerical order, giving permit numbers, and as soon as the tap is made the service installation bureau notifies, who in turn makes out a reader's slip and these slips are entered in the meter reader's books and are reported on by them from this time until the property becomes occupied. When occupied this report is turned in by the rate bureau to this bureau and the order for meter setting is sent to the central yard by us. When the meter is installed this and the rate bureau are notified and we make our records read accordingly.

All water services must be metered. Where services are installed to supply properties outside of the city, it is necessary for the owner to purchase the meter in all cases where we collect the rates. The plumber makes out an application, giving full description of the property to be covered, location of meter, etc., and, upon filing same with this Bureau, he is given a templet.

City Furnishes Meters.—The department of water supply furnishes, without cost, all meters up to and including 1-in. for residential purposes and up to and including 2-in. for commercial and industrial uses. The size of meter allowed is governed by the size and height of building, number of fixtures and the probable need of water. Where application is made for meter of a larger size than that furnished by the board, the owner pays the difference in price. In no case, however, will the Department set, or allow to be set, a meter larger than that which will accurately register the water consumed. The department sets all meters and in the case of large ones performs the work from gate to gate after the remainder of the work has been done by the plumber in accordance with blue-prints furnished him. All meters are sealed after setting. In considering the size of the meter to be furnished by the department, all combination of business and residence property, if one or more floors are devoted to business, is classified as business premises.

All fire lines must be metered, the cost of the meter being borne by the owner of the premises served. An up-to-date record, by means of a card system, is kept of all meter applications and installations.

Acknowledgment—The foregoing is taken from a "descriptive survey," published by the Department of Water Supply of Detroit, Mich.

Dry Square Braided Hemp for Yarning Joints

By OTTO S. REYNOLDS
Traveling Representative, The Leadite Co., Kansas City, Mo.

The merits and economy in the use of dry square braided hemp are so evident at this time that many water works engineers and superintendents specify it on all bell and spigot work. There are several hemp manufacturers who carry it is a regular item. There are many water works supply houses throughout the country who also stock this material in 50 and 25-lb. reels. The material is made up principally in three sizes. The ½-in. square is the standard size, which is designed to fit all diameters of bell and spigot pipe from 4 to 16 in., inclusive. The annular clearance in the bells is designed to be uniform for the same class of strength and weight pipe. The ⅜-in. square is furnished to meet the requirements when a spigot of fitting is entered into a pipe bell, the clearance being close. Likewise the ⅝-in. square is furnished to meet the requirements on reverse conditions.

Braided hemp for the water works field should be purchased of a good quality. The standard ½-in. size, free from any treating compound, should run about 16 ft. to the pound, the undersize, ⅜-in., 25 ft. to the pound, and the over size, ⅝-in., 10 ft. to the pound. The material should be of a reasonably long fiber hemp. Like a rope, the longer and better grade of the fiber, the better the hemp. It should be strong to withstand the punishment of the yarning tool when being forced into the bell and not shear in two or break allowing an opening for the molten jointing material to run through into

the inside of the pipe. This incident causes delay in the progress of the work. Besides it is an unpleasant thing to overcome. There is little difference in the cost of a short fiber hemp from a long fiber. Therefore, the longer fiber hemps are recommended.

In the use of square braided hemp the hemp is cut to length allowing a lap of about 2 in. for 4 and 6-in. pipe; 2½ in. for 8, 10 and 12 in.; and 3 in. for 16 and over. On account of the various makes of pipe, specific lengths to cut hemp would be numerous and difficult.

In application, a length of hemp is held on the extreme end of the spigot end of the pipe. The worker guides the spigot, holding it close to the top of the bell. At his word another man at the opposite end or leading bell end with a stick forces the entrance of the spigot into the bell, and the hemp rolls in on the bottom at the same instant. Be sure the pipe is "homed" well. Then with the yarning tool, without a hammer, push the hemp back to the bead or centering ring of the pipe on the bottom. This can be done easily, as the pipe is loose in the bell and care must be taken not to push the hemp over the bead or by the centering ring. Then with the assistance of a hammer, force the hemp in along both sides, and then on top letting the lapping end lead downward, that the molten material will not force an opening between the lap and on into the inside of the pipe. This completes the yarning. For lead, usually two raps around the pipe is taken, which leaves exactly 2 in. for the lead on standard pipe. For Leadite, but one strand is used, which leave 2½ in. depth for the Leadite.

This method of yarning does not require any special tools. No preliminary rolling or twisting is necessary. It does not require the skill of a mechanic to center it, pack it and space it for depths, as is required with the open jute. It will not burn through, as the material is very closely braided. A very nicely centered pipe is obtained, which is the success of any joint. A uniform depth is obtained for the jointing material, which effects a saving on the jointing material in that an exact amount of it is assured of being installed and little chance for an excess being used. As this method of yarning is very easily applied, greater speed is accomplished and there is very little chance of injury to occur. The pinching of the fingers, which often happens when centering up a pipe with wedges preparatory to installing open jute, is practically eliminated.

With Leadite as the jointing material, square braided hemp is highly recommended, because it is believed much better joints may be had, and, as only one-half the material is required compared with lead and open jute, it is without doubt more economical. Lastly, if a strand of open jute should be left extending outward into the bell and then the Leadite be poured into the joint, it would remain there forming a conductor for a water leak, which would require cutting out and repairing. The Leadite is not hot enough to burn up the open jute, as would be the case with molten lead.

In braided hemp there is practically no waste to the material. The hemp is cut to exact length. It is not used for a rag to clean mud from tools, the hands or shoes. It is not used to wipe out the bells or spigots of the pipe. It is not used for starting fires, nor is it used to wad up and place into the end of the pipe for over-night at the end of the day—and sometimes overlooked to be taken out the following morning. It will not drive over and into the pipe to float about and possibly clog up a service or stick up a meter, both of which are expensive maintenance charges. Lastly, if a piece of hemp is dropped along the ditch, it is recovered, which is never the case with open jute, as the latter gets full of dirt and the yarner will not use it.

Many waterworks superintendents and engineers feel that, over the older method of yarning with open jute, dry square braided hemp is well worth its additional first cost, and that very good economy is effected in its use.

Acknowledgment.—The foregoing is taken from the July Journal of the American Water Works Association. The matter was prepared for a subcommittee of the American Railway Engineers Association, on revising railway specifications for laying cast iron pipe. Data are based on practice in Indianapolis, Charleston, S. C., St. Louis, Fort Worth, and Independence.

Ohio Conference on Sewage Treatment

The third annual Ohio conference on Sewage Treatment will be held at Canton, O., on Tuesday and Wednesday, Oct. 22nd and 23rd. The headquarters of the conference will be at the Northern Hotel where the meetings will be held. Tuesday afternoon and Wednesday morning will be devoted to the presentation of papers and to discussions, with a dinner Tuesday evening. An inspection trip to the Canton and Salem sewage treatment plants will be made Wednesday afternoon. The Canton works comprise Imhoff tanks and trickling filters. The Salem plant is a new one of the activated sludge type and employs a number of the modern devices for sewage treatment. Salem is 32 miles east of Canton.

Papers are being prepared on the following subjects:

1. The Canton Sewage Treatment Works.
2. The Salem Sewage Treatment Works.
3. The Biological Oxygen Demand Test.
4. Operating Details of the Small Sewage Treatment Plant.
5. Sewage Disposal Litigation.
6. Discussion of the Sewer Rental Law.

The Ohio Water Purification Conference will be held at Columbus, Oct. 24th and 25th, with meetings at Fort Hayes Hotel. Those persons wishing to attend both conferences can drive to Columbus over good paved roads, a distance of about 130 miles.

Reservations at Canton should be made early at either Hotel Northern (conference headquarters), Hotel Courtland or Hotel McKinley. Reasonable rates can be secured at these hotels. For those planning to go to Columbus it is imperative that early reservations be made at Fort Hayes Hotel, there being two other conventions in Columbus at that time. In making reservations at either Hotel Northern at Canton or Fort Hayes Hotel at Columbus mention should be made of the Conference being held there.

On Saturday, Oct. 26th, Indiana plays Ohio State at Columbus. A block of seats has been reserved for those members of the two conferences wishing to attend the game. Application for tickets, accompanied by check (price $2.50 each), should be made to T. R. Lathrop, State Department of Health, Columbus, O.

A detailed program of the sewage conference will be issued later from the office of the State Department of Health. Floyd G. Browne is Secretary Ohio Conference on Sewage Treatment.

Market for Dried Activated Sludge.—The Sanitary District of Chicago has given considerable attention to the development of a market for dried activated sludge from its Des Plaines River sewage treatment works and its Calumet sewage treatment works, and in cooperation with the Milwaukee Sewage Commission the district has done a large amount of successful experimental and promotional work. According to the 1928 report of Edward J. Kelly, Chief Engineer of the Sanitary District of Chicago, the activated sludge has proved excellent for uses on golf courses, particularly on the greens, and in gardens. For 1928, the price has been set at $25 a ton, f. o. b. cars at Maywood, in small lots, and $22.50, f. o. b. cars, by the carload.

Sewerage in Wisconsin.—According to records of the Bureau of Sanitary Engineering of the State Board of Health, 211 municipalities in Wisconsin have public sewerage systems, 91 of which have provided disposal facilities through 106 sewage treatment plants. In addition there are listed 9 sewerage systems and 3 treatment plants of a semi-public nature. During 1928 plans for 34 new, modified or extended sewerage systems were approved by the bureau.

Encyclopedia Britannica's Fallacious Argument Against Water Metering

Speaking of the use of water meters the Encyclopedia Britannica says: "But the worst evil of the (meter) system, and one which must always prevent its introduction into the United Kingdom, is the circumstance that it treats water as an article of commerce, to be paid for according to the quantity taken."

This argument is perhaps the one oftenest used against the metering of domestic consumers of water. There is a subtle fallacy in it that has deceived, and continues to deceive, many a man. Since water is as necessary to life as is air, it is argued that it should be as nearly free as possible. Indeed, Britannica adds: "In the organization of the best municipal undertakings in the United Kingdom the free use of water is encouraged." Now the matter of fact is that there is no such thing as free city water, even in the case of the man who pays nothing directly for it, because he inevitably pays indirectly in the form of taxes. The water tax then becomes part of his monthly rent, and so is lost to his sight but not to the sight of his landlord. So the question resolves itself to this: "Is it preferable to pay for your water directly or indirectly?" Pay you must, in any event.

When payment is made directly and in proportion to use, men are apt to avoid waste. This is particularly true of water, electricity and gas. And, by the way, what is there about water that should cause it to be regarded differently from any other necessity that must be bought? Is it more necessary than food? As well might Britannica argue that food should be made free to the residents of a city as that water should be free. As well argue that the butcher should not weigh the meat and let the customer—and his dog—help himself ad libitum, as to argue that water should not be metered. Yet, deceived by the sophism of "Water Almost Free as Air," many a city (Chicago among the number) goes gingerly about the task of metering all its services. Why not make the sophism perfect by enlarging the slogan to read, "Food as Free as Air"?

There is a certain class of politicians who believe that it is popular to oppose universal water metering, yet where is the city that has ever adopted universal metering and afterward reverted to flat rates? The fact is that citizens are not such fools as some politicians imagine. Give them the facts about metering and their opposition soon wanes, if indeed such opposition has ever really existed on the part of the majority.

Reverting again to Encyclopedia Britannica's opposition to water metering, it should be remembered that in Great Britain there has developed a strong tendency to coddle the citizens, as contrasted with our American plan of encouraging each one to shift for himself. The British "dole" for the man out of a job is perhaps the latest evolution of that coddling policy. And what is the "dole" at bottom but an unmetered meal ticket? Just as "free water" encourages waste of water, so the "dole" encourages waste of time. To a pretty pass has this coddling policy brought that great empire. Seeing Americans marching steadily forward toward greater incomes, they attribute our progress mainly to natural resources. Well, if natural resources be the answer, they consist mainly in that part called resourcefulness—desire and ability to paddle one's own canoe.

Equivalent to a Semi-Monthly Municipal Magazine

Two of the *Gillette Construction Group* of magazines are so edited as to embrace the construction and maintenance features of municipal work, namely *Roads and Streets* and *Water Works and Sewerage.* For city engineers, superintendents, contractors and others engaged in municipal construction work, these two magazines are essentially one semi-monthly magazine, the one covering street work, street cleaning and traffic control, the other covering waterworks, sewers, and sewage treatment and disposal. The third magazine of the *Gillette Construction Group,* namely *Engineering and Contracting,* rounds out the picture for those who desire a complete view of progress in the civil engineering and contracting field.

City streets and country roads have been growing more and more alike ever since the advent of the automobile. It was perception of this fact that led us in 1916 to establish *Roads and Streets* (an offshoot from *Engineering and Contracting)* as a magazine useful alike to the city, county and state engineer engaged in highway design, construction and maintenance. As for the contractor in the highway field, the equipment

needed is the same inside as outside a city; and the methods of construction are usually identical. Indeed, were it not that those artificial boundaries known as "city limits," are often marked by signs, a motorist would usually not know when he had passed from the city street to the country road.

Roads and Streets is edited to serve those performing similar functions in the highway field, regardless of their titles. Snow cleaning, which was at one time confined to city streets, is a function that has spread to country roads. And the same is happening as to highway signalling and traffic control. Contrariwise, the cheaper forms of road surfacing (gravelling, etc.) that were formerly regarded as fit only for country roads, are being more and more used on residence streets until such time as the residents feel inclined to pay for permanent pavements. Indeed, there is no sound reason why any city or town street should ever be muddy, although many of them are no better than hog wallows in wet weather. In such cases the residents seem to think that until a permanent pavement can be afforded, they must go without any sort of surfacing. And so they wallow around for a decade, or a generation, waiting till they can afford a roadway, when they might, and should, have one somewhat short of perfection but at least smooth and solid. City engineers can often persuade residents in such cases to adopt some temporary type of surfacing that will eliminate all mud and dust; for, as to highways at least, a half loaf is far better than none.

The annual Road Show has become the mecca of city engineers as well as of county and state engineers, thus proving the community of interest of all who are engaged in highway work.

Water Works and Sewerage might be more briefly called Municipal Hydraulics, and that title was given consideration, but it seemed best to parallel the title of *Roads and Streets* by using two names that designate closely allied branches of the construction field. All consulting engineers, and nearly all city engineers, who specialize in water supply also specialize in sewage disposal. The same holds true of nearly all city contractors who engage in "ditch digging." So the wedding of these two names in the title of our magazine is merely the repetition of a wedding that has existed for generations between these two functions.

In America almost as much money is annually spent for new sewer as for new waterworks systems and betterments. And when the public has been fully convinced to the wisdom of not contaminating rivers, lakes and ocean beaches with sewage, the annual expenditures for sewerage systems will probably exceed those for waterworks.

A word in closing about *Engineering and Contracting*. We have recently added a section entitled "Nuggets of Knowledge on Methods and Costs," in which at least 50 short, nuggety articles are printed every month. This magazine aims to cover the engineering and contracting features of bridge and building construction, and of the miscellaneous structures of a civil engineering nature not covered by *Roads and Streets* or by *Water Works and Sewerage*.

The reader is referred to our advertising section for the subscription rates of these magazines when taken in combination.

The Twin Branches of Municipal Hydraulics

Without an exception consulting engineers who specialize in city waterworks specialize also in sewerage. These two departments of civil engineering are, and always have been, twin branches of one great tree —municipal hydraulics.

Water supply involves water disposal. A sewer is itself a water conduit differing hydraulically from a water supply pipe in that it does not carry water under pressure. But a sewer has the additional function of transporting refuse matter. It is perhaps the most economic conveyor of solids that man has designed, with the possible exception of the hydraulic monitor and sluice used in placer mining.

The primitive form of sewer, still to be seen in many European towns, is the gutter. Barely half a century has elapsed since our American towns began to equip themselves with sewer systems, but they have far outstripped the average European town in this respect. Our next great step will be to provide sewage treatment plants for practically all our towns, for we must not continue polluting our rivers.

The editor was much interested in seeing the ancient waterworks in Pompeii, which was destroyed by a Vesuvius eruption in 79 A. D. No sewer pipes were seen. The water pipes, which are small, are made of lead, and they look quite modern. Underground masonry aqueducts were the "supply mains." The public baths, with their devices for heating the water, are among the most interesting features of this ancient waterworks.

The early Romans solved many problems in hydraulics. Their aqueducts are remarkable engineering structures. Not less so are the massive arched sewers by which every street in Rome was drained into the Tiber. One of these sewers, 11x12 ft., is still in use.

More than 20 centuries ago men had devised and built remarkable water supply and water drainage systems in Rome; and even hundreds of years prior to that long aqueducts and reservoirs of large size had been built to supply many Mediterranean cities. The greatest handicap that the engineers of those early days had to contend with was the lack of iron or steel pipes for distribution of water and terra cotta pipes for removal of sewage. Lead was not only expensive but lacked strength. Bronze was even more expensive. They were driven to the extensive use of canals, long tunnels and masonry aqueducts. Magnificent as some of these structures were, the cost of their construction was enormous.

48th Annual Convention of New England Water Works Association

The 48th annual convention of the New England Water Works Association, held Sept. 17 to 20 at Portland, Me., while not the largest from an attendance standpoint, was one of the most interesting and successful meetings of the association. The total registration was 570, made up of 228 members, 111 associate members and 231 guests.

The opening session on Sept. 17 was devoted principally to the reading of reports of committees. The officers of the association also submitted their reports. The secretary reported a total membership of 830, of which 701 are active members. The treasurer reported that the invested fund totaled some $15,000. The Dexter Brockett medal, which is given each year to the author of the best paper presented before the association, was presented to Francis W. Dean, engineer and architect, Boston, Mass., for his paper, "Pumping Station Practice." This paper was published in the June, 1928, Journal of New England Water Works Association. An interesting feature of the session was the election of Sir Alexander Houston, the famous engineer of the Metropolitan Water District of London, England, to honorary membership in the association.

The afternoon and evening sessions were devoted to the presentation of technical papers. One paper that aroused particular interest dealt with color reduction in storage reservoirs. This was presented by Caleb Mills Saville, Manager and Chief Engineer of the Board of Water Commissioners of Hartford, Conn. Another paper of much interest was "Beauty in Water Works Structure," presented by John C. Stevens, the architect who designed some of the buildings for the Portland Water District. The other two papers dealt with the Portland Water District.

At the morning session on Wednesday two papers were presented. In one of these Percy Sanders, Superintendent of Water Works, Concord, N. H., described that city's experience with automatic chlorination. An abstract of this paper will be found elsewhere in this issue. The other paper, presented by Ralph S. Bauer, Mayor of Lynn, Mass., dealt with the financial administration of a water works. The afternoon was given up to a clam bake and sail on Casco Bay. The water works superintendents' meeting comprised the evening session. At this session the reports of the legislative committee and the committee on painting standpipes were presented. Three papers also were presented: "Test of Large Meters in the Field," by R. E. Ferguson, Assistant Superintendent Hersey Mfg. Co.; "Experiences with Diesel Engines in Water Works Plants," by A. D. Couch, Mechanical Engineer, Community Water Service, and "Diesel Pumping Units at Wayland and Wilmington, Mass. Mr. Ferguson's paper is abstracted in this issue.

At the Thursday session the following papers were presented:

"Method of Testing Cast Iron Pipe," by Wm. R. Conrad (abstracted elsewhere in this issue); "Some Uses of Aeration in Water Purification," by Malcolm Pirnie; a description of the water works improvements at Springfield, Mass., by E. E. Lochridge; "The Reconstruction of the Pumping Station of the Western New York Water Co.," by H. W. Huy; "Making of Water Works and Pressure Studies," by Herbert E. Smith.

At the morning session on Friday, Arthur E. Gorman presented a paper, "Watching the Weather in Safeguarding Public Water Supplies," and J. Frederick Jackson presented a paper entitled, "Enforcement with Other Beverages," which dealt with the control of bathing in public water supplies.

The entertainment features were as follows: Sept. 17, 1 P. M.—Maine clam chowder luncheon at new shops of Portland Water District, followed by inspection of shops and standpipe painting inspection. (Courtesy of Portland Water District.) 8 P. M.—Informal reception for ladies at Hotel Eastland. 8:15 P. M.—Theatre party for ladies. (Courtesy of Geo. F. West & Son.)

Sept. 18, 11:30 A. M.—Clam bake and sail, Casco Bay. (Courtesy of Water Works Manufacturers' Association, Inc.) 8 P. M.—Ladies' reception and bridge at Hotel Eastland. (Courtesy of Water Works Manufacturers' Association, Inc.) Sept. 19, 10 A. M.—Sightseeing trip for the ladies. (Courtesy of Portland Chamber of Commerce.) Followed by coffee at Portland Chamber of Commerce. 7:30 P. M.—Dinner dance and entertainment at Hotel Eastland. (Courtesy of Water Works Manufacturers' Association, Inc.) Golf tournament.

The officers elected for the ensuing year were as follows: Robert Spurr Weston, consulting engineer, Boston, president; George H. Finneran, superintendent water service, Boston, first vice-president; George C. Brehm, city engineer and director of public works, Waltham, Mass., second vice-president. The following continue in office: Frank J. Gifford, Dedham, Mass., secretary; Albert L. Sawyer, Haverhill, Mass., treasurer; Prof. Gordon M. Fair, Cambridge, Mass., editor.

Flume for Testing Models of Hydraulic Structure

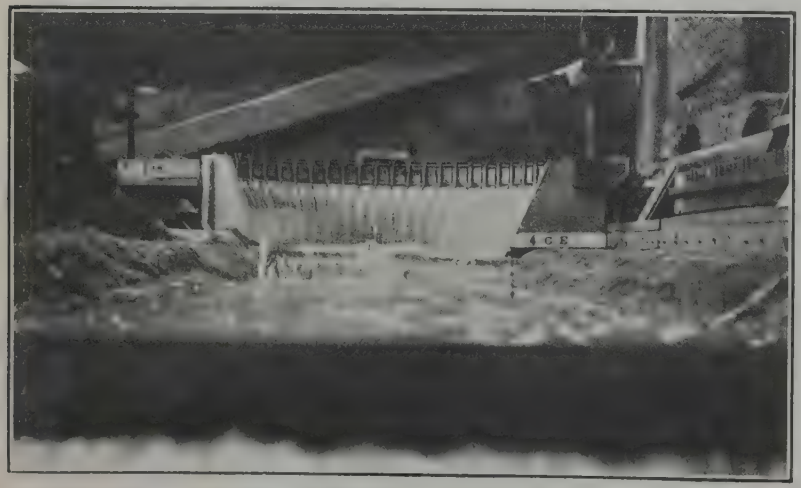
A flume for testing models of dams and other hydraulic structures has been recently installed in the new laboratories of the Carnegie Institute of Technology and experiments on a model of a commercial dam have already been made.

This flume is 72 ft. long, 13 ft. wide, and 3½ ft. deep, and is equipped with a centrifugal pump with a capacity of 3,000 gal. per minute. According to Professor Harold A. Thomas, associate professor in charge of the hydraulic department at Tech, it is probably one of the most suitable flumes in the country for testing hydraulic structures.

The flume is located in the new addition between the north wings of Engineering Hall. To the north of it is the materials testing laboratory, with its new equipment. The materials laboratory was moved from Machinery Hall to provide space for the new aeronautics laboratory.

Both undergraduate and research study will be made on models in this flume. Spillways, outlets, cushion pools and other hydraulic equipment will be tested. Model dams can be constructed and easily fitted into place and the stream of water controlled to reproduce the flow of a river on which the dam will be built according to the laws of similitude.

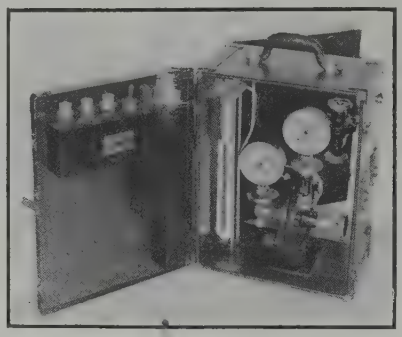
During the summer months commercial engineers have been cooperating with Professor Thomas on the model of a dam now being built in the south. The model, built on a scale ratio of 1 to 100, was constructed by Mr. William Pfouts, head instructor of patternmaking at Carnegie Tech. Every detail of the prototype was reproduced in the model. Even the topography of the river bottom was carefully reproduced with concrete. Professor Thomas states that other models will be tested in the near future.



Test Being Made on Model Dam at Hydraulic Laboratory, Carnegie Institute of Technology

A New Portable Chlorinator

The Paradon Mfg. Co. of Arlington, N. J., have recently developed an unique new portable chlorinator. The apparatus is housed in a tough fibre case,



New Paradon Portable Chlorinator.

constructed similar to a piece of hand luggage. When closed, it looks exactly like a piece of baggage, and will readily pass as such, making its transportation easy.

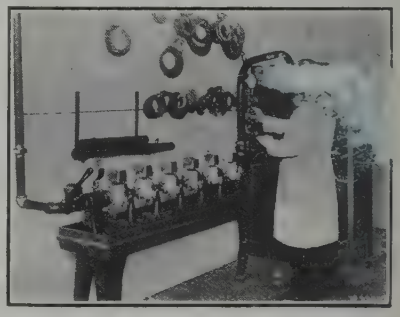
A complete standard dry feed Paradon chlorinator is used, fully equipped to the last detail. The unit is adaptable to continuous regular chlorinating service as well as occasional emergency use. A silver chlorine shut-off valve is provided, making it possible to keep the apparatus under chlorine pressure when not in use, thus preventing access of moisture and other foreign material, and allowing long periods of disuse with attendant deterioration of the unit.

No water supply is necessary for its operation. The apparatus can be supplied for any range of capacity from 1 lb. of chlorine per 24 hours to 300 lb. per 24 hours. Equipment can also be supplied that will decrease the minimum capacity to .03 lb. of chlorine per 24 hours. A chlorine testing outfit, spare parts, connection to main, and all other necessary accessories are contained in the carrying case of the apparatus. A similar fibre carrier is provided for two small cylinders of chlorine (12 lb. capacity each), and which can also be used in conjunction with the portable chlorinator.

The uses of the Paradon portable chlorinator are many, as, for sterilizing mains before putting into use, for eliminating after pollution in dead ends of mains, etc., for algae control, as a steady unit for regular chlorination, for the chlorination of emergency supplies due to broken mains, low water, etc., for the chlorination of water supplies used in connection with construction work on water sheds, for prechlorination, double chlorination, etc., also in sewage work for fly control, biological oxygen demand control, odor control; in fact, the portable chlorinator may be used to control the application of chlorine for any use that chlorine can be put to.

Testing Six Meters at One Time

The city of Bloomington, Ill., keeps close check on the revenue of its water department by regular testing of water



Meter Testing at Bloomington, Ill.

meters. The illustration shows the testing of six meters at one time with the Clark No. 622 meter tester, "weighing type." This multiple tester is stated to have effected very great savings in the testing costs of the department as well as insured accuracy of the meters —which has resulted in almost entirely eliminating complaints from consumers regarding charges.

Sewer Systems in Iowa.—Of the 920 cities and incorporated towns in Iowa, 319 have sewer systems. These systems serve 1,183,000 people, or 84.5 per cent of the total urban population. Of the 93 second class cities with populations ranging from 2,000 to 15,000 only one has no sewer system. Of the 96 incorporated towns with populations between 1,000 and 2,000, 85 have sewer systems. Of the smaller towns ranging from 500 to 1,000 in population nearly 50 per cent have sewer systems.

Water Works and Sewerage

Vol. LXXVI NOVEMBER, 1929 No. 11

Revolving Sprinkler and Dosing Chamber, Sewage Treatment Plant, Pontiac, Mich.

ow to Keep Sewage Filters in Operating Order

Successful Operation of Filters Can Be Secured Through a Complete Understanding of the Functions of the Filter and a Clear Knowledge of the Filter and Its Component Parts

By C. H. CURRIE

Currie Engineering Co., Webster City, Ia.

THE American Society of Civil Engineers and the American Public Health Association a few years ago adopted definitions of terms used in sewage treatment and define the two types of sewage filters as follows:

Intermittent Filter: A natural or artificial bed of sand or other fine grained material to which sewage is intermittently applied in doses and through which it flows, opportunity being given for filtration and also oxidation of the organic matter by bio-chemical agencies.

Trickling Filter: An artificial bed of coarse material, such as broken stone, clinkers, slate, slats, or brush, over which sewage is distributed and applied in drops, films, or spray, from troughs or drippers, moving distributors, or fixed nozzles, and through which it trickles to the underdrains, giving opportunity for organic matter to be oxidized by bio-chemical agencies.

The main purpose of each filter is the oxidization of the organic matter in the sewage, and the filters should be so constructed as to furinsh the best conditions obtainable for the bio-chemical agencies to perform their functions and to thrive.

Aerobic bacteria, upon which this oxidation depends and which is supplied by nature, require a home, which, in this case, is the surface of the sand or stone particles, and food, which is the organic matter in the sewage.

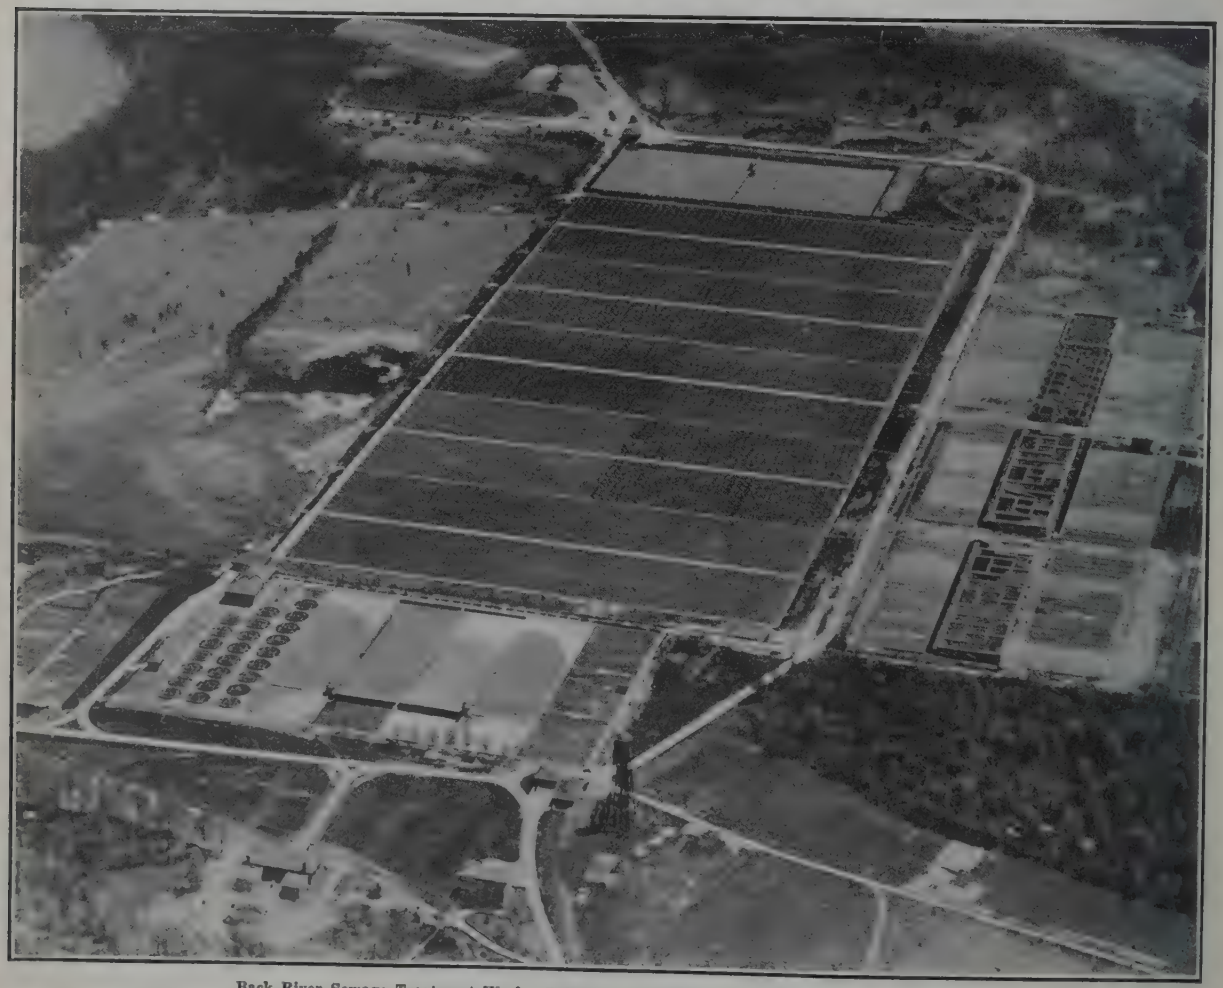
Many years of experience throughout the world have practically determined the various dimensions and capacities of both types of filter beds for various conditions, together with the most effective sizes of materials to be used in them. Granting that either type of filter bed is properly designed for the purpose intended, an equally important factor in results is the proper care in operation of these beds. No filter bed will function properly and efficiently unless it is properly cared for at all times, and the best of filters will soon be failures if neglected.

Intermittent Filter.—The artificial intermittent filter is constructed with underdrains rather close together, with a dirt ridge between each row of underdrains. The underdrain tile are covered with small gravel, the main purpose of which is to prevent the sand from washing into the underdrains. Over this gravel is spread from 18 to 24 in. of clean graded sand. The sizes of these sand grains and the cleanness of the sand are vital factors and most state boards of health specify cleanness, effective size, and uniformity coefficient permissible in this sand filter. A generally recognized dose of sewage, amounting to a 3-in. depth of liquid over the surface of the sand, is usually

designed for. This dose is conveyed onto the intermittent filters through surface pipes or troughs, carrying the liquid to all parts of the sand surface. It is important that the surface of the sand beds should be level and that the places where the liquid first strikes the sand surface should be protected from erosion by gravel or other material. After this dose occurs on any bed, it is advisable to give this bed a rest period of several hours to permit the sewage to seep on through the sand bed and provide a sufficient interval of time for the proper increase of the bacteria, which have been greatly depleted in their work of stablizing the sewage which has passed through it. It is obvious that the clogging of the surface of the sand will prevent this ideal condition; hence, the most vital operating need of the intermittent sand bed is a clean surface. No vegetation should be permitted to grow upon this sand surface and as the strainings of the solids carried over from dosage tanks are trapped in the upper thin film of sand, it is also necessary to keep this film well removed.

A small amount of work spent frequently on a sand bed is much more important than a great deal of work at infrequent intervals. In winter, it is necessary to provide ridges or piles of material at short intervals upon the sand surface, which will support a thin ice covering and permit the liquid to flow underneath this ice film during extremely cold weather. Some plant operators still build these ridges by furrowing the surface of the beds; others start in the early fall and rake up a thin amount of the upper surface with the solids attached in cone-shaped heaps, about 6 ft. apart. This latter practice would seem to be better, inasmuch as the level surface is not disturbed and when the winter is over, these heaps are easily removed without mixing any of the dirt deeper into the sand. With the furrowing system, it is necessary and important to carefully scrape all the upper dirt from the furrow before the sand is re-leveled, and even then, there is a grave danger of mixing the dirt into the upper few inches of the sand bed, which eventually will cause clogging and will necessitate the removal of this depth of dirty sand. If the operator has clearly in mind the need of maintaining a clean bed of sand at all times and never disturbs the surface below a very shallow depth, he should experience no serious difficulty in securing excellent operation. In the course of a year, some amount of the sand bed is necessarily removed from the surface and when this amounts to as much as from 4 to 6 in., the upper surface should be scraped clean and additional proper sand added.

Properly operated, the sand filter bed is probably the most efficient means of sewage purification today, although the operating cost may be somewhat higher than that of the stone beds. Neglect or other factors may cause a sand bed to become so clogged throughout its depth that renewal of the sand becomes necessary. If such a condition exists, a study should be made as to the relative economy between removing and washing the sand as against the removal of the sand and replacing the same with new sand. The tile underdrains may fail and the operator should dig down and investigate the underdrains, should they appear to be



Back River Sewage Treatment Works, Baltimore, Md., Showing Trickling Filters in Center

sluggish, and replace defective tile where needed.

The practice of some operators in by-passing their sand filters during cold weather is an admission of lack of intelligent operating ability on their part. Freezing of underdrain tile may cause many of the tile to disintegrate.

While sand filters may not perform as efficiently in cold weather as in warm, ice-covered outlet streams demand the best purification possible, if fish life is to survive.

All openings in surface distributors should be so adjusted that a uniform amount of sewage flows from each one.

Trickling Filter.—Inasmuch as the total surface area required for trickling filters is not over one-tenth that of the intermittent filter, the floor or bottom of the stone bed is generally constructed of concrete, as well as the side walls, and the expense of a superstructure over the entire bed is often justified. The underdrain tile, quite closely spaced, should drain into a common outlet and have a gallery at each end for inspection and cleanout purposes. Over these underdrains are usually placed 6 ft. or more of hard stone, generally varying from 1 to 3 in. in size, although some filters have smaller stone and others somewhat larger. The sewage is distributed over this stone bed in such a manner as to secure an even amount of liquid over every square foot of surface, if possible. The general custom in America is to accomplish this by means of spray nozzles from dosing or equalizing tanks on the lines of distribution to insure a varying head which tends to secure an even distribution over the surface. Because of the coarser material used and because of the rapidity with which the bed can empty itself of a dose, the rest period as needed in the intermittent filter, is not required with the trickling filter, and many authorities now consider that a very short cycle between doses, even as low as five minutes, may be highly desirable. The important thing in the operation of a properly designed and constructed filter is: First, keep the nozzles clean so the sewage may be distributed evenly over the entire surface. Matches, cloth, and other material may get through the clarifiers and catch in the nozzles or distributors. In keeping these clean, the operator should be careful in handling his particular distributor so as not to damage the mechanism of distribution. Screw and "key" nozzles are easily bent in removing and may seriously interfere with the distribution intended. Occasional removal of the nozzles at the ends of the distribution lines for a short flushing period may be advisable in some instances. Second, watch for ponding on the surface of the bed and stop this ponding as soon as it appears. Third, see that underdrains are clean.

There are various ways in which ponding may be relieved, some of which should be successful with any individual plant. Some operators find the use of a hose in washing down the surface stone breaks up the ponding. Others find that stirring of the upper surface of the stone stops this. Still others find that resting of the bed from dosage for a one-day period often relieves this situation; still others find that the use of chlorine in the dosing chamber for a short period of time will clear up the surface of the beds from ponding. Each operator can determine for himself the needs of his particular stone bed upon trial, and should, of course, use the easiest and most inexpensive method first until he has determined the one best suited to his particular bed.

The underdrains should be accessible for observation and cleaning, and if any of them show evidence of clogging, they should be kept clean at all times. The uniformity of underdrain flow in the underdrains may indicate the uniformity of distribution over the surface of the bed.

The writer's observation over a period of many years convinces him that those sewage plants operated or cared for by men who have a mental picture of the construction of their plant, together with an understanding of the functions of the various units of his plant, are generally the plants which produce satisfactory results, and the poorly operated plants (which are many) are generally operated by men who do not thoroughly understand what they are to do or why they are to do it.

It is to be hoped that the day is not far distant when the vital importance of intelligent sewage plant operation will be recognized by the people and laws passed to secure this much needed condition, or existing laws properly enforced.

Acknowledgment.—The above is a paper presented Oct. 23 at the 11th Iowa Sewage Treatment Conference at Iowa State College, Ames, Ia.

Advantages to Householder of Water Softening

An interesting outline of the advantages of softened water to the average householder was given in Vol. 93, 1929 Transactions of the American Society of Civil Engineers, by C. W. Foulk, Professor of Analytical Chemistry, Ohio State University, Columbus, O. He stated that the Columbus plant removes from 180 to 190 parts per million of hardness from the Scioto River water. This, if left in the water, would destroy about $6 worth of soap per year in the average household. (The household price of soap is taken at 10 ct. per pound.) On the basis of 50,000 households in Columbus, $300,000 worth of soap would be wasted each year. This waste is eliminated by the softened water.

Considering the positive gains arising from the use of soft water, attention is called to the following items in the construction and operation of a house, which are needed in a hard-water city, but not in one with a soft-water supply:

100 bbl. cistern	$110
Electric water pump	120
Installing pump	20
Extra plumbing	50
Total	$300

This means that it costs $300 less to build a house in Columbus than to build the same house under the same conditions in a hard-water city. If interest and depreciation are calculated, it is seen that there is an annual saving of from $25 to $30, because of the soft-water supply.

Long Sewer Outfalls in California

In the earlier outfalls in Southern California, the length from shore was set arbitrarily, even in the case of large outfall sewers, such as that for Los Angeles. The lengths of the more recent outfall sewers have been gauged from the behavior of B. Coli fields of pollution determined from pre-existing outfalls. The outlets are generally made to discharge from upturned ells lying on the ocean floor, in order to avoid their becoming clogged with shifting sand, and to prevent the transmission of water hammer. In a discussion in the September, 1929, Proceedings of the American Society of Civil Engineers, R. F. Goudey, Resident Engineer at Los Angeles of the California State Department of Public Health, gives the following examples of long outfalls in California that have a vertical discharge:

Long Outfalls with Vertical Discharge

City	Population, present	Treatment	Diameter, in inches	Outfall Length, in feet	Depth, in feet
Los Angeles	1,250,000	Screening	84	5,400	63
Orange County	60,000	Screening	42	2,700	40

The Consumption of Water and the Effects of Metering

Maximum and Minimum Per Capita Consumption for Various Purposes—Comparative Growth of Metering—Effect of Meters on Water Consumption—Reduction in Consumption Due to Metering

By LYMAN M. VAN DER PYL
Chief Chemist, Pittsburgh Equitable Meter Co.

THE path followed in the study of water supply systems extends far back to antiquity, and it is indeed a fascinating story to follow through the ages. Ancient wells are still furnishing water in Egypt and India; some of the water tanks at Aden in Arabia, built probably more than 2,000 years ago are still used in supplying the modern city with water. Athens, Carthage and Loadicea and other ancient cities had their collecting and distributing systems, but undoubtedly the most famous system was that of Rome which is said to have supplied according to various estimates, from 50 to 400 gal. per capita daily around 100 A. D.

From those figures to that of Paris in 1550—1 quart per capita per day—is a far cry, and the difference probably explains why the ravages of pestilence were so widespread in mediaeval days. Even in 1700 Paris was supplying only 2½ quarts of water per capita per day. Since then, with the development of modern collecting and distributing systems the increase in water consumption has helped immensely in raising the standard of living and in making possible the growth of our large cities. At the present time in the United States there are more thas 9,000 communities with water supplies and the domestic consumption ranges from 15 to 75 gal. per capita daily.

The amount of water consumed involves a statistical study of great importance to the water works man in planning future changes and enlargements, and it is the purpose of this article to give briefly an account of the influences that have bearing on the quantity of water that must be supplied to satisfy the demand.

The actual consumption of water is determined in a number of different ways. One common method is to compute it from the number of strokes of the pumps, knowing the piston displacement and applying a correction factor for pump slip. Weirs are sometimes used, especially in the case of gravity systems, but probably the best results are obtained by using some sort of a meter. Irrespective of the manner of obtaining the figure, however, this total consumption includes all the water sent into the mains, including waste and leakage as well as water actually used.

The study of water consumption naturally begins with the division of the supply according to the major purposes for which it is used. Such a classification is of course, useful in laying out different parts of a distribution system, as for instance when an extension is to be made in a manufacturing or in a residential district. For this analysis it is customary to divide the total supplies into five classes, as shown in Table I (Jour. Am. W. W. Assoc. [1915] 181) where the consumption is divided according to the actual figures of a number of cities of different sizes.

In the table are listed only cities in which the consumption of water is wholly metered or very nearly so, as obviously any other method of obtaining consumptions would result in nothing more than estimates. As may be seen there are wide divergences between the various cities in the amounts of water used by the various cities and a discussion of the various factors responsible for these differences is in order.

Table II—Maximum and Minimum Per Capita Consumption of Water

Use	Gallons Per Capita Daily Minimum	Maximum	Average
Domestic	20	50	35
Commercial and industrial	10	50	30
Public	5	15	10
Loss	15	40	25
Total	50	155	100

COMPARATIVE GROWTH OF METERING IN SEVENTEEN CITIES

City	Year	Number Meters	Year	Number Meters	Year	Number Meters

*Includes commercial use.

Domestic Consumption. — The domestic consumption of course, depends largely on the personal habits of the people of the community, and to a considerable extent the water used is an indication of the standard of living. The following figures, averaged from the statistics of 14 cities present the domestic use in different types of dwellings (Jour. N. E. W. W. Assoc. 27, [1913] 55):

	Gal. per capita per day
Apartment houses	62
First class dwellings	54
Middle class dwellings	34
Lowest class dwellings	15

It is worth noting in this connection that the amount of water used is increasing, even in metered communities.

A decidedly variable item in the domestic consumption figure is the water used for sprinkling lawns and gardens; in dry localities, of course, more water is used in this way than in places where

Table III—Effect of Meters on Water Consumption

Total	68	11,275,238	1,306.68	45–200	110	1,970,979	930,839	47

the rainfall is heavier. For sprinkling lawns 7 to 8 gal. of water are required per 100 sq. ft. of surface and inasmuch as lawn sprinklers and garden hose nozzles will pass from 225 to 660 gal. of water per home (Jour. N. E. W. W. Assoc. 28 [1914] 377), the amount of water used in this manner will be considerable; in Denver, 10 per cent of the total supply is said to be used in this way.

High distribution pressures have a very direct bearing on domestic consumption. Hartford, Conn., for instance, saved 300,000 gal. daily or approximately 4 per cent of its total demand by throttling its valves. (Eng. Rec. Feb. 5, 1916, p. 184.) The introduction of sewers will increase the use of water in some instances as much as 100 per cent; incidentally it has recently been suggested that the cost of extensions to sewer systems be apportioned among the properties using them according to their respective water consumptions as determined by meter readings.

Industrial Consumption.—Industrial requirements for water vary with the nature of the industries served; tanneries, laundries, chemical works, and paper mills are large consumers, while water for steam generation is a considerable item in most industrial demands. In some localities industries draw their own water from rivers or from their own wells and there is practically no industrial demand, while in some cities the industrial load is more than half the total water consumed. Commercial users of water embrace not only stores and hotels but also rooming and apartment houses.

Water for public uses is generally furnished free and unmetered though often the amount of water so used is considerable—13.6 per cent of the total consumption in San Diego, Cal., and in Lexington, Ky., in 1914 (Proc. Am. W. W. Assoc. [1915] 191-195). It includes water for schools, public buildings, parks, street sprinkling, road construction and fire fighting.

The last item, "loss," is sometimes called "unaccounted for" or perhaps more aptly "waste." It covers leakage from mains and fixtures, under-registration of meters and careless or wasteful use for purposes legitimate in themselves. Metering will minimize the last named waste and any persisting waste will be metered and paid for. In a meter system, the total loss should not be greater than 20 per cent of the whole consumption; the loss then would be largely due to leakage from mains and careful inspection will keep this at a low figure.

As averages of the above figures, Turneaure and Russell (Public Water Supplies p. 22) give the figures shown in Table II, applying to supplies having good metering systems.

Minimum or maximum sizes for all purposes are not likely to occur at the same time, so that the totals of minima or maxima are extreme figures. Probably a normal minimum could be 60 gal. per capita daily while a normal maximum would be close to 125 gal.

In unmetered system the normal total consumption would not be far from 150 gal. per capita daily as against an average 100 gal. per capita in metered systems. Under especially favorable conditions, the consumption in the unmetered system might use as high as 300 gal. per capita daily; for example, Chicago in 1921 was using 276 gal. per capita daily while Coeur d'Alene, Idaho, used 316. (Flinn, Weston and Bogert, Waterworks, Handbook, p. 578.)

Variations in Consumption.—The figures given above show the average daily demands over a long period of time, but there are variations, sometimes of considerable magnitude, existing over short periods. Of course, all parts of the supply and distribution systems must be made large enough to supply the greatest demand that will be imposed on them and it is consequently necessary to study these variations.

The usually accepted figures are that the maximum monthly rate will be 125 per cent of the average, while the maximum daily rate will be 150 per cent of the average; for smaller cities, however, the maximum daily rate is likely to be over 200 per cent of the average rate. Further, the maximum hour will draw water at 150 per cent of the rate of the maximum day. Consequently the system should be capable of delivering 150 per cent of 150 per cent, or 225 per cent, of the average consumption. If the system is also to be used for supplying water for fire fighting, it should be capable of handling in addition 150 to 200 per cent of the average. In large cities, incidentally, the fire consumption should be about 50 per cent of the average, while in very small towns it may be as high as ten times the average rate.

REDUCTION IN CONSUMPTION DUE TO METERING IN CITIES THAT HAVE ADOPTED A UNIVERSAL METERING PROGRAM

City	Universal Metering Adopted Date	Per Cent of Services Metered				Per Capita Consumption				Population Time of Adoption	Estimated Population July 1, 1925	Per Cent Increase	Maximum Rate Per 1,000 Gallons Cents

METERS MANUFACTURED 1910-25
(five manufacturers)

Year	No. Meters	Year	No. Meters
1910	295,000	1918	340,000
1911	310,000	1919	330,000
1912	340,000	1920	410,000
1913	325,000	1921	390,000
1914	365,000	1922	490,000
1915	375,000	1923	560,000
1916	410,000	1924	575,000
1917	385,000	1925	640,000

Finally, in making provision for future demands on the water supply system, the future increase in population must be estimated; this is done by interpolating past rates of growth of the city and by comparing with the growth of other cities of similar size

making allowances, of course, for the different characteristics of the two cities. Cognizance should be taken as well of the fact already noted, that the average rate of legitimate water consumption is increasing. As systems become more nearly completely metered, however, the rate of decrease of illegitimate consumption will more than compensate for the rate of legitimate increase until the rate of meter installation drops down.

Despite the prejudice against water meters in certain sections and notwithstanding the objections to their installation raised as political expedients it is worth noting that of the municipalities that have adopted them not one has ever gone back to the old system. (Eng. News Record, Feb. 7, 1918, p. 269.)

Reduced Waste with Meters.—Countless numbers of cases where water meters have reduced the waste of water may be cited, and in every case the reduction is very marked. Table III from the report of the Engineering Board of Review to the Board of Water Commissioners of Denver shows clearly that water consumption decreases as the percentage of services metered increases. Another tabulation by Hill (Eng. News-Rec. 79, 1917, 312) groups 68 cities with a total population of more than 11,000,000 according to their per capita consumption, as shown in Table IV; as may be seen the percentage of meters to total services falls rapidly as the consumption rises. As a specific instance the case of Boston shows a rapid decrease in the rate of consumption as the number of meters increases.

With such practical unanimity of opinion as exists on the value of metering and with a realization of the axiomatic equity of the system of paying for water actually received, it is difficult to class those approving the installation of meters as anything except proponents of an antiquated and unfair method of taxation. Just as the gas industry was forced for its own protection to turn from flat rates to meters, so will the water supply industry, both public and privately owned, turn eventually and completely to meters, and that far before the millenium is reached.

Acknowledgment.—The foregoing is reprinted from October Water and Light, the journal of the southeastern section of the American Water Works Association.

Cost of Pumpage at Dubuque, Ia.—The following taken from the 29th annual report of the Water Department of Dubuque, Ia., shows the average cost of pumpage for the year ending March 31, 1929:

	Per 1,000 Gal.
Operating and maintenance only	$0.0662
Operating, maintenance and depreciation	.0914
Operating, maintenance and interest	.0770
Operating, maintenance, depreciation intercst	.1062

Some English Notes on Activated Sludge Process

By ARTHUR J. MARTIN

Whenever a new and promising process for purifying sewage makes its appearance people are apt to jump at the conclusion that existing methods are doomed to be discarded. We had an instance of this 30 years ago on the advent of the septic tank, and history is repeating itself in the case of the activated-sludge process. This process has undoubtedly come to stay, but it is far more likely to supplement the older methods than to supersede them.

In the first flush of enthusiasm, too much was expected of the process, and it has been asked to do work for which it was not really suited. A common mistake was to rush the sewage into the aeration tank without adequate preparation. It is now realized that a preliminary settlement is desirable, and our old friend the sedimentation tank is accordingly coming into its own once more.

And it is by no means certain that it is always wise to dispense with filters. An activated sludge tank is very sensitive to change in the composition of the sewage. A sudden rush of liquid trade wastes may kill the organisms in the sludge, in which case it may take months to get it back into condition. The bacterial films in a trickling filter are hardier, and, as Mr. Whitehead, the engineer to the Birmingham, Tame and Rea Drainage Board, points out, the margin of aeration in a filter, and consequently its ability to cope with exceptional states of the sewage, is infinitely greater than given by any activated sludge plant.

Mr. Whitehead's predecessor, Mr. Watson, has drawn attention to another very significant point. The purification effected by the activated-sludge process is at first very rapid, but it soon slows down. Sixty per cent of the impurities of the Birmingham sewage are removed in the first hour; it takes five hours to remove another 30 per cent. A trickling filter would do it in an hour.

Sewage which has been treated for an hour with activated sludge is free from colloidal matter, and is much more readily oxidized than sewage which has merely passed through a sedimentation tank. As a result of this improvement, the quantity which can be purified by each cubic yard of filtering material is more than doubled.

Owing to the rapid growth in the population of the drainage district, the board was faced with the necessity for laying down an additional acre of filters each year to keep pace with the increased volume of the sewage. To obviate this need the board have laid down aeration tanks, or, as Mr. Watson prefers to call them, "flocculation tanks," between the sedimentation tanks and the filters. By so doing they increased the capacity of the filters twice or threefold, and the need for laying down any more beds has been indefinitely postponed. Not only so, but the nuisance which has been experienced from smell and from flies has been absolutely done away with.

Purification Standards.—Before designing works to purify sewage, we must know how far the purification will have to be carried. No question in connection with sewage has given rise to keener controversy than that of the standard of purity which should be aimed at. Opinions differ widely as to the nature of the tests which should be applied to effluents, their severity, and more particularly as to whether the standard should be enforced in all cases.

Various chemical tests have been proposed, framed, we may suspect, with more regard to the convenience of the chemist than to their actual value in practice. The rivers boards which have been set up in certain watersheds have adopted standards of their own, mostly different, which they apply to the effluents discharged into their rivers.

Too often these standards have been regarded as an end in themselves, instead of as a means for safeguarding the purity of the river. Little regard has been paid to the circumstances of individual cases, such as the character of the stream and the relative volumes of the diluting water and the effluents.

Lord Iddesleigh's Commission made an earnest attempt to put an end to this confusion, and recommended a common-sense standard to be applied in ordinary cases. In order to comply with this standard, the effluent must not contain more than three parts per 100,000 of suspended matter, nor absorb in five days more than two parts per 100,000 of dissolved oxygen. This standard, however, was not to be applied indiscriminately, for, as the Commissioners pointed out, the dilution afforded by the stream is the chief factor to be considered. When the volume of the stream, as compared with that of the effluent, is great, the standard should be relaxed, and with the dilution exceeding 50 volumes, all tests might be dispensed with.

All the standards now in force or proposed relate solely to the chemical qualities of the effluent. No one has yet ventured to advocate a biological standard. But it should never be forgotten that a sewage effluent, however highly it may be purified, is not suitable for use as drinking water. For the danger from sewage lies not in its chemical impurities, but in the possible presence of the germs of disease, and these are not destroyed nor removed with certainty by any of the processes in ordinary use. The effluent from a sewage works, however efficient, must therefore be regarded as potentially dangerous.

Sanitary Aspect of Lake Michigan Diversion Case at Chicago, Illinois

A Non-Controversial Discussion of Chicago's Problem: Historical, Present Sewerage System—Efficiency of Sewage Treatment—The Water Supply—What Filtration Will Accomplish

By L. R. HOWSON

Alvord, Burdick & Howson, Consulting Engineers, Chicago, Ill.

FOR many years, the diversion of water from Lake Michigan by Chicago for sewage disposal purposes has been the subject of bitter controversy, culminating in a suit in the United States Supreme Court started about three years ago. The importance of the issue may be judged by the fact that about two-thirds of the people of the United States are parties in the litigation. The Supreme Court appointed Charles Evans Hughes as special master to take evidence which extended over a two-year period. In January, 1929, the Supreme Court made its initial findings, which required the Chicago Sanitary District to dispose of its sewage by means other than lake water diversion. This decree, when effective, will result in the discharge of part or all of the sewage plant effluents into the lake from which the water supply is taken. The practicability of safeguarding the public health under this program has been the subject of much debate. It is this phase of the case to which this discussion is directed.

A brief historical outline of Chicago's sewage disposal and water supply problems may assist toward an understanding of sanitary problems which the court's finding imposes upon the Chicago district.

Historical.—Chicago and the industrial region adjacent to it occupy the southwestern shore of Lake Michigan. The topography is comparatively level and most of the ground lies at an elevation less than 20 ft. above Lake Michigan. The city started near the mouth of the Chicago River, which was a small sluggish stream with a total drainage area of approximately 307 square miles, being made up of two branches, known as the north and south branches, which unite about one mile west of the mouth of the river.

The first sewers, as well as the first municipal water system, were built in 1856, at which time the city had a population of about 80,000 people. The occupied area was then so located that most of the sewers naturally drained directly to the main branch of the Chicago River and thence discharged directly to the lake. As the growth of the city increased, the expansion took place to the west, north and south, the natural drainage of which was either to one of the branches of the river or directly to the lake. The water supply has been taken from the lake from 1856 to date.

By 1890, the population had increased to 1,209,000 people and at the present time, exceeds 3,500,000 in the Sanitary District.

The discharge of the sewage into the lake within close proximity of the water works intakes resulted in high rates of water-borne disease in the Chicago district, the typhoid death rate reaching a peak figure of 173.8 per 100,000 in 1891.

In 1886, a drainage and water supply commission, known as the Hering, Artingstall and Williams Commission, was appointed to make a complete investigation of the subject of water supply, sewage disposal and drainage for the City of Chicago. This commission advised the construction of the drainage canal with a capacity of 10,000 cu. ft. per second and the construction of intercepting sewers which would divert the entire sewage from the lake and discharge it mixed with water drawn from Lake Michigan into the upper Des Plaines and thence into the Illinois and Mississippi water sheds.

As an outgrowth of this report, the legislature of the state of Illinois in 1889 passed the Sanitary District act and shortly thereafter the people of the district voted affirmatively on the creation of the Chicago Sanitary District.

Plans were prepared for the construction of a channel extending from a connection with the south branch of the Chicago River at Robey St. to a connection with the Des Plaines River near Lockport, a distance of some 28 miles. Construction was undertaken and the canal completed and placed in service in 1901 and since that date, the flow of the Chicago River has been from rather than into Lake Michigan.

The Calumet District to the south and east of Chicago continued to drain into Lake Michigan. In 1911, the construction of a channel known as the Calumet-Sag channel was started to divert the normal flow of the Calumet River from Lake Michigan to a connection with the drainage canal at approximately mid-distance between the Robey St. and Lockport ends of the canal. This channel was designed with a capacity of 2,000 cu. ft. per second. It was completed in 1922 and since that date, the flow of the Grand and Little Calumet Rivers has been away from rather than into Lake Michigan at such times as the stream flow did not exceed the carrying capacity of the canal and its connections.

The construction of the main drainage canal and the Calumet-Sag branch effected a remarkable improvement in the Chicago death rate from water-borne disease and to a large extent removed the sewage nuisance from the streams themselves. This result has, however, been accomplished by transferring the bad conditions in the Chicago and Calumet Rivers to the Des Plaines and Illinois Rivers in which nuisance has been created, all fish life killed and other damage resulted for more than 100 miles downstream. The Des Plaines and Illinois Rivers today are practically an open sewer for 150 miles distance from Chicago.

The important facts with respect to the typhoid death rate in Chicago are as follows:

Average for five years prior to opening of canal reversing flow—34 per 100,000.

Average for five years after opening of canal reversing flow—28.4 per 100,000.

Average for five years after completion of intercepting sewers diverting sewage from the lake—12.1 per 100,000.

Average for five years after the pasteurization of milk and the start of water chlorination—5.9 per 100,000.

Average for five years after complete chlorination of water supply—1.2 per 100,000.

The upper part of the diagram (Fig. 3) shows the typhoid statistics for Chicago for the period from 1890 to date. In this diagram are indicated the dates at which sanitary improvements were placed in service so that their effects may be visibly indicated.

The lower half of the diagram shows for comparison another important typhoid death rate reduction accomplished by water filtration, to which reference will be made later.

On Jan. 14, 1929, the Supreme Court of the United States delivered an opinion with regard to the diversion of water, which denied the right of diverting water at Chicago except that negligible quantity, if any, which might be required for navigation in the Chicago River as a part of the Port of Chicago.

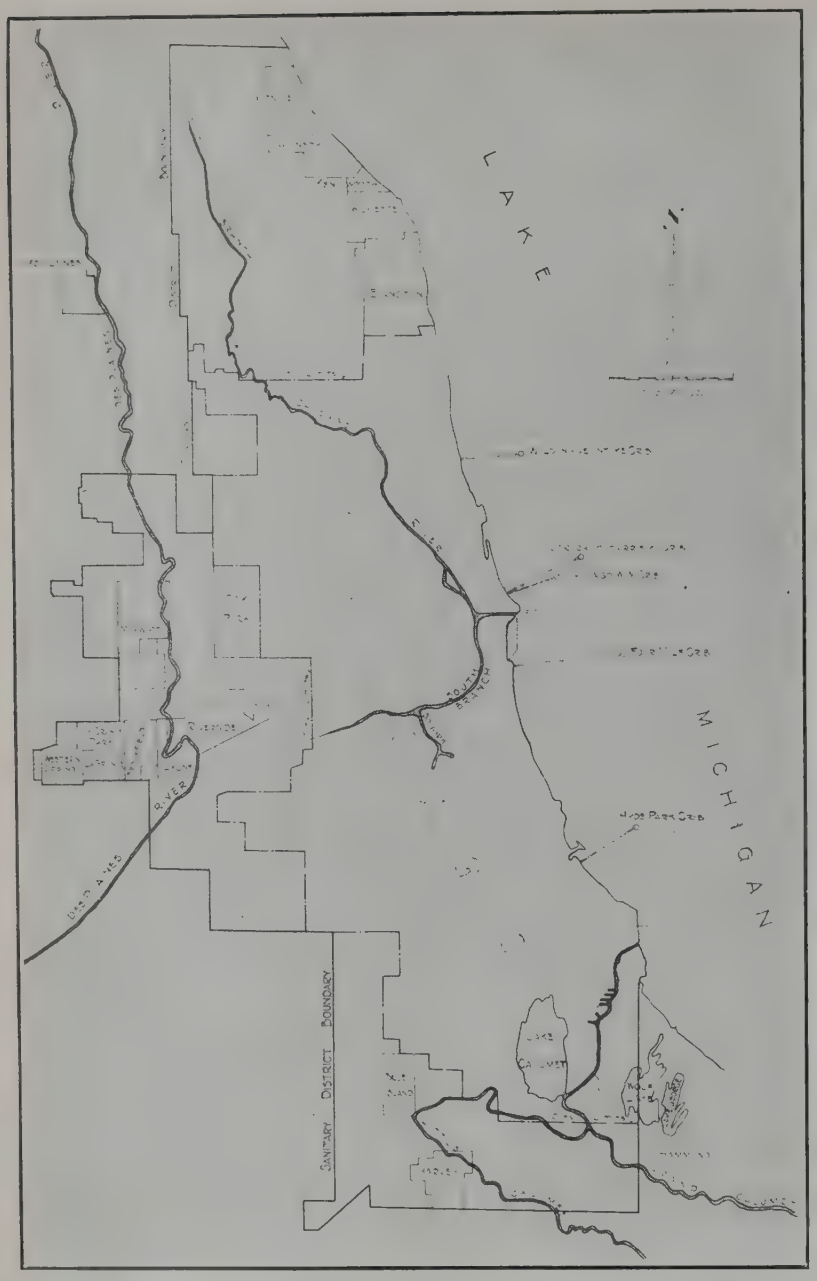

Fig. 1—Drainage Channels in the Chicago Sanitary District Prior to Diversion

In keeping, however, with the principles on which Courts of Equity condition their relief and by way of avoiding any unnecessary hazards to the health of the people of the Chicago section, the Supreme Court decided to so frame its decree as to accord to the Sanitary District a reasonably practicable time in which to provide some other means of disposing of the sewage, at which time there shall be a final permanent operative and effective injunction. The special master, Mr. Charles Evans Hughes, was instructed to take such further evidence as would enable him to advise the court as to:

1st: What negligible amount, if any, of diversion was necessary for navigation in the Chicago River as a part of the Port of Chicago.

2nd: What sewage disposal works would be necessary to care for the sewage of the Chicago district by means other than diversion.

3rd: What period would be required for the construction of such works.

This decree, when effectively carried out, will result in a part or all of the sewage plant effluent and storm water overflow being discharged into Lake Michigan, from which the water supply is taken. The water supply and sewage disposal problems at Chicago are and always have been one problem, though administered by two governmental agencies.

Present Sewerage System.—Sewerage in the Chicago Sanitary District is almost entirely on the combined system, although the Hering, Artingstall and Williams report, made in 1887, recommended separate sewers for the then outlying areas. Had that recommendation been adopted, nearly 80 per cent of the present sewer mileage would have been on the separate system and over 50 per cent of the population would have been tributary thereto. The problem of building intercepting sewers and of caring for storm water overflows would have been much simplified.

The Sanitary District now has under construction a comprehensive sewage disposal program including four major and several minor projects.

The North Side sewage treatment works have been finished. This is an activated sludge plant designed to serve approximately 800,000 people.

The West Side project, to serve 1,915,000 people as of 1945, has been started, originally as Imhoff tank treatment only, later to be followed by sprinkling filters, but since the Supreme Court decision, the Sanitary District has modified its plans for this plant so as to make it an activated sludge plant.

The Southwest side plant, which is to be located directly across the main drainage canal from the West Side plant, has not as yet been started. It is now planned to be an activated sludge plant to serve 1,320,000 people in 1945. The large stockyards organic load will be handled at this plant.

The Calumet project has been designed as an Imhoff tank and trickling filter plant to serve approximately 400,000 people. The tanks have been in operation approximately seven years. The sprinkling filters and secondary sedimentation are now included as a part of the Sanitary District's program to comply with the requirements of the United States Supreme Court.

Efficiency of Sewage Treatment.—While there has been some divergence of opinion, as reflected in the testimony, as to the quality of an activated sludge plant effluent, the operation of the Milwaukee plant, the largest yet in full operation, has demonstrated that the effluent from such an activated sludge plant in the sizes contemplated for Chicago, will be practically clear, odorless, colorless and stable and that the process will have removed at least 95 per cent of the suspended solids, at least 95 per cent of the bacteria, 98 per cent to 99 per cent of the b. coli and 96 per cent of the biochemical oxygen demand. It will contain 5 to 7 p.p.m. of dissolved oxygen and oxygen in the form of nitrates and nitrites up to 15 p.p.m. Based upon the Milwaukee operating experience, the remaining B. O. D. will be about 10 p.p.m. or less. It will be

permanently stable, that is, it will not again putrefy if stored in an open vessel or discharged into a water course in which it constitutes the total flow.

With a combined system of sewers, all of the sewage flow cannot be passed through the disposal plant on account of the relatively high ratio of storm water to sanitary flow. This necessarily results in the by-passing of some sewage during storms. It has been estimated that approximately 1½ per cent to 2 per cent of the sewage flow may reach the river channels untreated during the year, the exact percentage depending quite largely upon the capacity of the interceptors and the proportion of first storm flows which are carried through the plant.

The amount of storm water which could be discharged into the various water courses if all of the sewers were running full is approximately 12,000 c.fs. The interceptors are capable of taking about 4,000 c.f.s. to the disposal plants so that in extreme conditions 8,000 c.f.s. of mixed storm and sanitary flow would reach the streams.

The effluents from the various plants could be chlorinated so as to effect practically 100 per cent of b. coli removal if desired. It is somewhat more difficult to chlorinate the storm water overflow from over 300 separate outlets. All of this flow which may reach the lake, however, has to pass out through either the main Chicago River or the Calumet River and while the applying of chlorine to such large volumes has not been attempted to date, the results obtained in chlorinating raw sewage in large volumes would indicate its practicability. At the Cleveland Easterly plant, where the raw sewage from over 500,000 people is chlorinated, b. coli reductions have averaged over 96 per cent for the past three years and have exceeded 99 per cent when a chlorine residual of about .3 p.p.m. was carried.

So far as the sanitary aspect of the water diversion case is concerned, the question becomes one of the effect of activated sludge plant effluent and storm water overflows primarily upon the water supply and to a lesser extent upon the bathing beaches.

The Chicago Water Supply.—The Chicago water supply is drawn through four intake cribs located from three to four miles off shore and connected by tunnels to the 12 major pumping stations. The water receives no treatment other than chlorination.

About two-thirds of the time, the water drawn from the Chicago cribs is clear. It is often quite pure for short periods. However, its sanitary quality cannot be depended upon and for a considerable portion of the time at all of the intake cribs, it is distinctly bad. The water as delivered to consumers is often decidedly turbid for weeks at a time.

During 1927, the turbidities varied from 1 to 115 p.p.m. with a yearly average of 11.5 p.p.m. for all stations and 17.8 p.p.m. at the 68th St. crib. The water from the 68th St. crib had an average turbidity for a month of 50.4 p.p.m.

The net result from a sanitary standpoint is that the water as chlorinated has been good. The taste is frequently objectionable and the turbidity exceeds 10 parts per million on the average approximately 30 per cent of the time.

Filtration of the present water supply has been recommended by all conversant with the problem for a number of years. Filtration, however, carries with it the prerequisite of metering, for at the present time Chicago is pumping approximately 300 gal. per capita per day and the cost of filtration plants, sufficient to care only for the water wasted, would approximate $30,000,000. It has been estimated that if Chicago were to install meters on all services, in a 10-year period, there would be saved in the next 25 years $233,000,000 in operation and construction costs. In addition, it has been estimated that approximately $50,000,000 would be saved in the cost of intercepting sewers and sewage disposal plant construction. With complete metering, the quantity of water pumped, which it is assumed

Fig. 2—Drainage Channels in the Chicago Sanitary District After Diversion

is substantially the same as the sewage flow, will be approximately 1,000 cu. ft. per second between 1935 and 1940.

What Filtration Will Accomplish.—Filtration has demonstrated its ability to treat highly polluted waters satisfactorily. Among the notable examples are Niagara Falls and the Ohio River cities (Fig. 3).

Niagara Falls, whose water supply is polluted by the fresh sewage of Buffalo and environs, was one of the most important typhoid centers of the country, prior to filtration in 1913. The typhoid death rates were as high as 185 per 100,000 and averaged 125.8 per 100,000 for the 14 years preceding filtration. Following the start of filtration there were 18 months with no deaths from typhoid and the average typhoid death rate since filtration has shown a reduction of over 95 per cent from that prevailing prior thereto.

On the Ohio River city after city, from Pittsburgh to Cairo, takes its water supply from the river, returning the sewage again to the stream, the water being used again and again by the cities downstream after filtration. The b. coli index of the raw Ohio River water frequently exceeds 100,000. Filtration and chlorination produces from it a safe water supply.

In addition to the bacterial removal filtration will, of course, remove the turbidities now prevailing in the Chicago water supply.

Filtration will insure a clean water for Chicago 365 days in the year. Filtration should be installed at Chicago regardless of whether the diversion from the lake is zero or 10,000 c.f.s.

Chicago's Problem.—The Supreme Court having already decided that all diversion, except such negligible amount, if any, as may be required for navigation in the Chicago River, shall cease, the Chicago district is confronted with the necessity for devising such means of caring for its sewage and of protecting and purifying its water supply as will adequately safeguard the public health.

Among the measures available to accomplish this result, are the following:

1. The treatment of all sewage other than storm water overflow through the most efficient type of treatment plants which experts on both sides have agreed to be the activated sludge process.

2. The chlorination of the sewage disposal plant effluents.

3. The chlorination of all storm water overflows by carrying a residual chlorine content of approximately .3 part per million in the liquid flowing into the lake through the Calumet and Chicago Rivers.

4. The metering of the water supply which will make filtration practicable.

5. The filtration of the public water supply utilizing the present intakes and standard filtration methods.

6. The abandonment of those intakes nearest to the mouth of the rivers and the substitution therefor of a super-intake located approximately 20 miles to the northeast of the mouth of the Chicago River.

7. The modification of the standard filtration processes by double coagulation as is extensively practiced on the highly polluted Ohio River supplies or the adoption of excess lime treatment.

8. Sanitary control and sterilization of the bathing beaches.

9. Should the Supreme Court allow a diversion from the lake for navigation purposes in the Chicago River equivalent to the water supply and the run-off from the Chicago River watershed, it would be practicable through the operation of controlling works located at the river mouth or at the head of the canal to prevent any outflow of either sewage plant effluent or storm overflow to the lake.

Opinion as expressed in the hearings before Mr. Hughes has differed as to the measures or combination of measures which might be necessary to adequately safeguard the public health and the writer does not intend in this paper to discuss these controversial matters. It must, however, be apparent that if sanitary engineering science has not sufficently developed to safeguard the health of the Chicago community through a combination of sewage treatment and water purification works, a large part of the population of this and other countries is destined to live under unsanitary conditions. Chicago, in contrast to Milwaukee, Cleveland, Toledo and other important lake cities, is the only one at which diversion from the lake was a practicable possibility. Can anyone successfully argue that Cleveland or Milwaukee must cease to exist because of the necessity for living under conditions which are now to be imposed upon Chicago? The facts are that Cleveland's typhoid death rate with water filtration but with only 10 per cent to 15 per cent sewage treatment and Milwaukee's with complete sewage treatment, but with chlorination only of its water supply, are substantially the same as Chicago's under the present conditions of diversion from Lake Michigan. Certainly, Chicago with proper treatment of its sewage and with adequate purification of its water supply can continue to function and expand without detriment due to the decision of the Supreme Court.

Recreational Use of Reservoirs

Practice of the Department of Water and Power of the City of Los Angeles, California

By CARL WILSON

Laboratory Director, Department of Water and Power, City of Los Angeles, Calif.

AMONG the numerous phases of sanitation in connection with water supplies the question of recreational use of reservoirs impounding water intended for domestic consumption is one of perennial recurrence, seemingly incapable of final solution, at least for certain social elements.

From Cloud to Kitchen Tap.—First of all, as waterworks men and public officials, we are pledged to protect our consumers and to serve them with water which is not only safe, but which is made appetizing to thinking people by a history of clean antecedents all the way from cloud to kitchen tap. Can we afford to ignore this obligation in order to gratify the selfish instincts of a small proportion of the population? The demand to open our lakes does not proceed from a real necessity which must be satisfied—rather it is a luxury, to be indulged as becomes a luxury, certainly not at the expense of others.

We are told by those who advocate recreational use that fees can be imposed for the privileges granted, and the money so raised employed in police measures to prevent pollution of the water. Insofar as the majority of hunters and fishers are concerned the writer likes to believe such measures would be completely effective, but he has had too much experience with self-styled sportsmen to think we can depend upon patrolmen for the high degree of protection we require, and this statement is not to be considered in any degree as impeaching the integrity of these guardians of public safety.

The Advance of Sanitation.—Sanitary engineers tell us it is not only possible, but practicable, to convert the sewage of a city into pure and safe drinking water. Under the stress of circumstance this is already being done, while such procedure will probably become commonplace in the future, yet the thought of drinking reclaimed sewage is repugnant to most people. They want their drinking water kept clean all the time. It is true that purification methods have been so developed that it is possible to convert a grossly polluted river water into a safe supply for human consumption, but to accomplish it the works must be carefully designed and built and constantly watched by highly intelligent and thoroughly trained operators. Even then we find only too frequently that an outbreak of disease occurs through failure of some unit in the process in an unexpected manner. Where only a grossly polluted supply is available reliance must be placed upon purification, but in Southern California, where our raw waters are exceptionally pure, is it not better to maintain their purity than to run the risk of polluting them through human contact?

Recreational Use of Least Importance.—A committee on "Sanitary Conservation of Streams," reporting to the Eighth Annual Conference of State Sanitary Engineers at Chicago, states: "Strenuous efforts must be made to preserve the cleanliness of streams now in that wholesome condition."

The same report, when discussing the order of precedence of use of water resources, states:

"There can be no question that the use of water resources as the source of public water supplies is the first and highest use." Other uses, in order of precedence as set forth by this committee are, sewage disposal, navigation, manufacturing, industry, power, irrigation, agriculture, fishing, or recreation, as may be dictated by local circumstances. Recreational use seems to be regarded as of least importance. Is it wise to wilfully and knowingly run the chance of adding pollution of the most dangerous type to our water just because we think we can take it out? The writer does not believe such practice can be justified by any argument.

The Aesthetic Side of the Question.—Behind the questions of technology, and perhaps of greater effect upon the public mind, is what may be described as the aesthetic reputation of our water. Most people are fastidious in matters pertaining to food, and the present world-wide campaign to popularize knowledge in sanitary and hygienic matters is making them more exacting in this respect. Can we afford to ignore the demand of particular people that the public water supply shall not only be safe, but surrounded by such a clean and inviting environment as to create the belief that it is wholesome and appetizing.

Los Angeles Prohibits Recreational Use of Reservoirs.—For the last eight years Los Angeles has prohibited recreational use of her reservoirs, and we believe the results attained prove the wisdom of our action. Filtration is not practiced, reliance being placed upon natural purification during storage, supported by chlorination. Of course, natural purification in an impounding reservoir is not compatible with recreational use, for it demands at least thirty days' storage amid surroundings where re-pollution cannot take place. We depend upon and benefit through such natural processes to some degree, even in our terminal reservoirs, all of which store water for significant periods, and we cannot afford to sacrifice this advantage, which is really our margin of safety. Without filtration we have an enviable record for a safe water supply—not a single case of typhoid has been ascribed to our water since it has been municipally owned, a period of 27 years. Would our record have been as good had we permitted recreational use of our lakes? Perhaps, but the chance is great that the story would have had a different ending.

The Situation at Los Angeles.—The proposal is frequently made that remote reservoirs might be thrown open to public use, leaving those nearer the point of consumption completely protected. Under some circumstances it might be proper to adopt such a policy, but the Los Angeles system does not lend itself to such a compromise. Our Haiwee reservoir is 200 miles away from the city, in the midst of a practically desert region, but it is, biologically speaking, the key to our system. For more than a hundred miles to the north and west the Sierras send their creeks to feed Haiwee, and natural purification processes in this unique reservoir are depended upon to remove all pollution which may have occurred upon the catchment area, 3,300 square miles in extent. This immense drainage basin is one of California's greatest playgrounds, and no restriction of its use is required or contemplated. The public may hunt, fish, camp and otherwise enjoy this wonderland to the utmost, and Haiwee reservoir will function as a natural barrier to prevent the ill effects of intimate human association with the lakes and creeks from going beyond. But this will be true only if we prevent all pollution of the water in the reservoir. There must be an unbroken period of not less than 30 days during which natural purification can proceed to completion, hence we feel we must also deny recreational use even on our most remote lakes.

During the course of talks to clubs and schools in Los Angeles the writer has frequently put the question as to whether those present preferred recreational use of our reservoirs, and the response has always been overwhelmingly in favor of prohibition. Frankly, I believe this to be a true reflection of public preference in the matter and it has, at least in part, influenced our policy of restriction. Certainly those officials who are held personally responsible for the protection of over a

million and a quarter of human lives against the ravages of water-borne disease are not anxious to wilfully incur any risk, but must always err, if they err at all, upon the side of safety. We must be too strict rather than too lax, and it seems to me that we can conscientiously do nothing less than prohibit recreational use.

Acknowledgment.—The above is an abstract of a paper presented Oct. 25 at 10th annual convention of the California Section of the American Water Works Association.

Meter Testing and Adjusting Bills

By V. E. PERRY

Manager Water Sales Department, Spring Valley Water Co., San Francisco, Calif.

It has been the custom of the Spring Valley Water Co. ever since September, 1918, when San Francisco became 100 per cent metered, to test meters upon the request of a consumer who has a large bill and for which we have been unable to locate the cause.

Let us take, for example, a consumer who has had an increase of about 25 per cent or more in his bill and has received our usual letter (see Fig. 1) calling his attention to the increase and offering to make an examination if the excess has not been accounted for. If, after a careful examination of all the plumbing fixtures and check-up of the house piping, we are unable to account for the increase, we then order the meter tested. We use either of two methods of tests—one is an official test in which the city light and water inspector supervises the test, and the other is an unofficial test. The only difference in these tests is that the light and water inspector is present only in the official test. The test consists of measuring the water through the meter into a tank holding 10 cu. ft. Should a meter test within 2 per cent of 100 per cent efficient, we do not change the instrument, but for all meters that are either fast or slow 2 per cent or more we order a change for a new shop tested meter. As a rule, no increases are made for slow test meters. Our rules governing meter tests, copy of which has been accepted for filing by the Railroad Commission of the State of California, are as follows:

Rule 2. "If a consumer questions the accuracy of a meter supplying his premises, the Company will, upon the request of the consumer, cause an official test to be made at its own expense, provided the meter had not been tested within the period twelve (12) months prior to the date of said request. The consumer shall be notified of the time and place of such test, and may be present if he so desires.

(a) "In case the meter is found to be registering more than two per cent in excess of the actual quantity of water passing through it, another meter shall be substituted therefor, and the Company shall refund to the consumer the overcharge, based upon the correct meter readings, for a period of not more than twelve (12) months last past, unless it can be shown that the error was due to some cause, the date of which can be fixed. In the latter case the overcharge shall be computed back to, and not beyond such time.

(b) "Should more than one test during the year be demanded by a consumer, he shall deposit one (1) dollar with the Company and the test be made as provided in the preceding paragraph. Should the meter be found to register not more than two per cent in excess of the actual quantity of water passing through it, the deposit shall be retained by the Company. Should the meter be found to be registering more than two per cent in excess of the actual quantity of water passing through it the deposit shall be returned to the consumer and adjustment made as provided in the preceding paragraph."

We go a step further than the rules call for by making our adjustments for all meters that are 2 per cent or more fast. Our rules state "more than 2 per cent fast."

During 1928 out of 102,413 active metered services we tested only 494, or about ½ of 1 per cent. Of these 494 meters tested, 217, or 43.9 per cent, were found to be 100 per cent efficient; 193, or 39.1 per cent, were found to be slow; and only 84, or 17.0 per cent were fast. Of the 84 fast meters, 42, or 50 per cent, were 1 per cent fast; 21, or 25 per cent, were 2 per cent fast; 16, or 19 per cent, were 3 per cent fast; and 5, or 6 per cent, were 4 per cent fast.

In accordance with our rules, we refunded for the above fast meters the sum of $71 as follows: for 2 per cent fast $22.18, for 3 per cent fast $31.91, for 4 per cent fast $16.91.

As our gross revenue for 1928 was $6,565,450, our refunds account of fast meters of $71 were only about 1/1000 of 1 per cent of our 1928 revenue. This we believe to be a very favorable showing.

Acknowledgment.—The above paper was presented Oct. 24 at the 10th annual convention of the California Section of the American Water Works Association.

Recarbonation Equipment Installed at Manhattan, Kan.—With a view to facilitating softening and eliminating troubles due to after-precipitation, the city of Manhattan, Kan., has recently installed recarbonation equipment, the first in the state, as an adjunct to its water-softening plant. The equipment burns natural gas to produce the carbon dioxide.

SPRING VALLEY
WATER COMPANY

Safeguarding Public Water Supplies

How Weather Conditions Affect Quality and Safety of Supplies

By ARTHUR E. GORMAN
Wallace & Tiernan Co., Newark, N. J.

DURING the last few weeks many New England cities and towns have sought permission from their respective state boards of health to use water from secondary and possibly doubtful sources due to shortage in their regular supply caused by prolonged drouth. Still how many of the officials in charge of these waterworks had kept sufficient data relative to deficiency in rainfall on their watersheds to enable them to predict this shortage and the approximate time the emergency would have to be depended on? And what is more—in how many instances had definite plans been made in advance as to the procedure to be followed when forced to use the emergency supply?

Planning for Emergencies.—A shortage of water for a public supply is a potential health hazard. Every water works system has its one or more weak points regardless of how well it was designed, built and is operated. It is encumbent on the directing waterworks officials to know these weak links when tested by every strain which may be brought on them by those elements called "weather" or any combination of them. He must know his factors of safety under normal conditions, under the extreme conditions which occur seasonally each year and under the most extreme conditions which may be expected every five years and every decade. Not only should he know this, but he should have developed a plan of action to be followed out during emergencies. A plan not housed in a vague way in his own mind but a plan which has been discussed carefully with his assistants and still better practised and put in writing for ready reference.

The average water works operator properly trained will carry on satisfactory under normal conditions and probably do reasonably well under somewhat unusual circumstances. But, these are not the conditions which precede outbreaks of typhoid fever and other water borne diseases. Sharp outbreaks or epidemics come as the result of a collapse in the fabric supposed to exist for public safety. They usually follow a simultaneous combination of circumstances which in accordance with the laws of probability will not be repeated in many years. It therefore behooves the careful water works officials always to be on the alert for emergencies.

One Emergency Problem.—Let us take up one emergency problem and some of its possibilities.

As practical water works men what would happen at your plants if it should rain at an excessive rate of precipitation for say three consecutive hours? Would your dam hold? Would flooding of sewers or sewage polluted streams affect your reservoir, clear well or tunnel shafts? Would water short circuit through your reservoir and cut your theoretical storage of forty days down to forty hours, thereby losing your factor or safety due to storage? Would your supply become turbid, necessitating the use of chemical coagulants? These are all possibilities at the more common type of water works in New England.

Chlorination Control System at Chicago.—During the four years that the writer was charged with the safety of Chicago's water supply, a control system for chlorination was developed which was based largely on a program of "watching the weather." Chicago's intakes in Lake Michigan are fixed. The sources of pollution of the lake are known. Therefore from a control standpoint it became necessary to learn all we could about those factors which would bring this pollution to our intakes. Our studies involved rates of rainfall and the effect of run off into the lake, the time and probable duration of river reversals, the effect of dispersion, the rate of drift of pollution in the lake and the influence of prolonged winds and barometric pressures on the lake levels. Automatic recording rain gauges at four places in the city made it possible to predict—even while the rain was falling—the probable affect the run off would have on the direction of flow of the rivers. Flow vanes at key points in the river equipped with alarm lights and bells gave warning of reversals; recording gauges showed river elevations while automatic recording instruments for wind direction and velocity told the story of what might be expected in the way of drift of pollution toward the intakes once it entered Lake Michigan. In other words, we studied our weak points, planned our campaign for control so that it might be put into operation while the emergency was brewing. Without such a system there would have been four or five occasions each year when we had no real factor of safety and would have operated on a wide margin of chance with the health of 3,000,000 as the stakes.

In the writer's opinion any unusual change in weather conditions, such as—excessive rainfall, high winds, prolonged drouth, excessive heat or cold—warrants the application of emergency operation pending investigation. No harm can come from playing safe. In Chicago with a predicted southerly wind the orders for increase in the chlorine to be used for sterilizing water from intakes exposed to potential pollution were always given. During the periods of rainfall the chlorine dosage was always raised at least ½ to 1 lb. per million gallons at all pumping stations as a safety factor against possible pollution of water in tunnels from sewers located near land shafts. Whenever emergency orders were issued they were not withdrawn until the results of bacterial examination of special samples collected during the emergency had indicated it was safe to do so.

Checking Special Measures Important.—From an operating standpoint it is highly essential that every water plant keep regular routine records of operation. But for protection it is of the utmost importance that whatever special measures are taken during emergency periods be checked for results obtained. Special raw water samples at the height of an emergency, supported by equivalent samples of the water delivered to consumers during the emergency and while your precautionary program is functioning, are of inestimable value. They not only tell you the story of the extent of your emergency by means of which you may be guided in the future should similar circumstances develop, but they serve as your protection in case of controversy resulting from the emergency itself. At Chicago we prepared for these emergency samples by storing special sterile bottles at all sampling points and having emergency sampling equipment on hand at the laboratory for immediate use at any time.

Weather Conditions Should Be Studied.—It is obvious that the smaller water works cannot afford to have the expensive equipment considered necessary at large cities. But still there is no reason why the officials of smaller water works cannot apply fundamental precautions indicated as desirable through a keen study of weather conditions and their relation to the peculiar conditions at their respective plants. Make it a point to study the affect and influence of every unusual period of weather on the operation of your plant and the quality of the water delivered therefrom. Watch for the unusual with that unceasing instinct which makes the experienced Yankee sailor put into port with the first threat of a so' easter.

The water works official who is always on the alert for the unusual rarely has to meet with serious emergencies. He instills into his men that element of watchfulness and carefulness which prepares them to meet the more than average emergency with calm. He steels them to a degree of efficiency and discipline which makes it possible for him to get prompt and effective response to his directions when the real emergencies arise.

Emergencies of any kind in supplying safe water to consumers have a distinct public health aspect. For this reason it is the part of wisdom for the water works officials to take into their fullest confidence the health officers charged with supervision over public water supplies. The weak points in any water works should be known to the health officer. His advice should be sought in establishing a control program. He should be notified of emergencies as they develop or threaten. Your experiences reported to him may save the day for some other water works at a later period; or conversely a warning from him based on a report from some other operator may be just in time to permit you to take the proper control measures. An outstanding example of this is the cooperative program developed through the Ohio River Interstate Stream Pollution Agreement for notification through the state departments of health of water works operators of spills of phenol wastes on the Ohio river watershed.

In conclusion, this paper is a plea to the water works officials to "watch the weather"—that they may know its relations to the weak features of their respective plants; that they may work out an effective plan of action when emergencies arise; and that they may work in full harmony and cooperation with the proper health authorities in producing for the consuming public at all times, clean, safe, wholesome water.

Acknowledgment.—The foregoing is an abstract of a paper presented Sept. 20 at the 48th annual convention of the New England Water Works Association.

Leakage and Wastage at Cambridge, Mass.—The report of the Water Board of Cambridge, Mass., for the year ending March 31, 1929, contains the following:

In 1919, a pitometer survey was made on the system. The City was divided into twenty-two sections and a careful inspection was instituted for leakage and wastage. This year the city was again surveyed, and in seventeen sections the consumption was practically the same as noted in 1919. But in five sections the consumption had increased from 50 per cent to 100 per cent. This increase may be traceable to the additional population due to the construction of apartment houses, of from 20 to 30 suites, which replace the demolished old houses formerly containing one or two families.

Electrically Illuminated Fountain for Filtration Plant

An electrically illuminated fountain, having a number of unusual features, has been installed recently in the park at the filtration plant at Peterborough, Ontario. The installation was described by R. L. Dobbin, General Manager of the Utilities Commission of Petersborough in a recent issue of the Contract Record, from which the notes following are taken.

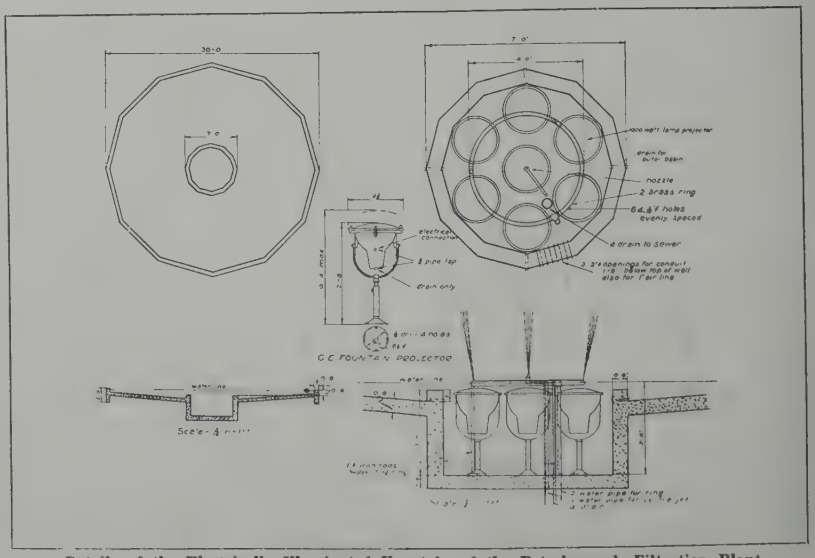
The fountain was designed and installed by the staff of the Petersborough Utilities Commission. It is designed along somewhat unusual lines specially for night illumination purposes.

The fountain itself consists of a shallow pool, dodecagonal in shape, with a center well which houses the lighting projectors and water jets. This is indicated in the detailed drawing. When the fountain is not operating, the only thing visible in the 30-ft. pool is the center nozzle and the top of the 4-ft. spray ring which is half submerged in the center. When in operation the spraying apparatus, of course, is not visible.

The seven projectors, supplied by Canadian General Electric Co., are of the submerged type, each containing 1,000 watt lamps. The one in the center, immediately under the central nozzle, contains a clear lens and the six others arranged on the points of a hexagon (in alternate corners of the dodecagonal wall) under the spray ring are red, green and amber—two of each color.

Current at 110 volts, a.c., is supplied to the projectors through underground lead cables from a flasher that is located in a manhole at a short distance from the fountain. With this arrangement, various combinations of colors are obtained and the flasher may be adjusted while the fountain is in operation. The central jet of water attains a height of 35 ft. and the outer 4-ft. ring of fine spray a height of 10 ft.

During the summer the ever-changing colors against a background of green trees and shrubs have attracted a host of visitors to the park and filtration plant.



Details of the Electrically Illuminated Fountain of the Peterborough Filtration Plant

State and Municipal Bond Election Results During September

New state and municipal bond authorizations reported during September broke all previous records for this year, according to The Daily Bond Buyer, of New York, whose regular compilation shows authorizations by 83 states and municipalities totaling $84,308,700. This compares with $16,870,199 in September last year, $13,372,949 in September, 1927, and $36,164,949 in 1926.

The unusually large total of authorizations last month is largely accounted for in the $55,000,000 program of the city of Philadelphia and $16,200,000 for the state of Maine. Other large items were $3,500,000 Hidalgo and Cameron Counties, Texas, Water Control and Imp. Dist. No. 9, and $1,000,000 Spartanburg, S. C., Sanitary Dist.

Issues defeated amounted to $10,182,600, as compared with $9,707,500 in September last year, $12,292,250 in September, 1927, and $4,178,500 in 1926. Among the larger projects defeated by the taxpayers of 34 communities were $4,070,000, Jefferson County, Texas; $3,000,000, Tacoma, Wash.; $800,000, San Augustine County, Texas, and $453,000, Falls County, Texas, Road Dist. No. 4.

A 22.4-Year Cycle in Rainfall and Its Cause

Analysis Employs Tree Growths, Clay Varves and Sunspot Records Guided by Electromagnetic Whirl Theory

By HALBERT P. GILLETTE

THE accompanying chart shows a rainfall cycle of about double the so-called 11-yr. sunspot period. It is particularly interesting in that the supernormal rainfall of one 11-yr. period is almost exactly offset by the subnormal rainfall of the succeeding 11-yr. period. This chart was recently sent to me by Mr. Burt Harmon, Hydraulic Engineer of the Water Department of Long Beach. I have inserted the dates of the Jupiter sunspot cycle, showing both its date of maximum and minimum effect. It will be noted that Mr. Harmon's 11-yr. periods should be shifted about a year to the right to correspond with the Jupiter sunspot dates; but that doing so does not appreciably alter his calculations of excess and deficient rainfall for each of the 11-yr. periods.

In an article published in "Municipal News and Water Works," October, 1928, I had shown that it is sunspots of south polarity that cause barometric lows, and that it is their preponderance over sunspots of north polarity that largely determines the amount of rainfall. Coupling this fact with Hale's discovery that the leading sunspots have opposite polarities in the sun's two hemispheres and reverse their polarity about every 11.2 years at about the time of sunspot minimum, I had indicated the reason for a 22.4-yr. rainfall cycle; but none the less I was surprised by the striking character of Mr. Harmon's chart. I decided, therefore, to test my theory more fully by taking the data of radial growth of pine trees for 500 years, as given by Douglass, checking the quantitative facts derivable therefrom against my theory. Table I shows the result of this analysis, which yields an almost perfect check of theory against fact for 43 out of 45 cycles of 11 years each. Had all 45 cycles checked the theory as did the 43, such an occurence could happen by mere chance only once in 35 trillion times. However, taking only the 30 cycles subsequent to 1570, in which not one departs from the theory, the probability ratio is ½ raised to the 30th power, making the odds about one billion to one that this coincidence is not fortuitous. Since the theory is thus shown to be in accord with the facts, by odds that are overwhelmingly against the accordance being accidental, it may be regarded as being established as true in so far as it explains the phenomenon in question.

Briefly reviewed, the theory of this phenomenon is as follows: The sunspots, as Hale has proved, are electromagnets, often of tremendous power. Any magnet causes free electrons to rotate around the magnetic lines of force, as laboratory experiments have shown. Electrons thus rotating themselves constitute an electromagnet, as is clearly seen in the case of solenoids. The earth itself is an electromagnet and so is the air above it, for both contain free electrons that are carried around by the earth as it rotates on its axis. Hence, these two magnetic fields must give rotation to free electrons in the air, that is, they must generate cyclonic whirls of electrons in the air. But such whirls in turn are electromagnets and tend to migrate under the action of the magnetic fields. The fields that may effect such migration are numerous, including certainly the earth's two great fields, the sun's great field, the fields of the sunspots and the fields of the planets.

The fact that cyclones rotate in opposite directions in the earth's two hemispheres is in accordance with the theory that the two magnetic poles of the earth would produce opposite rotations of the cyclones. If an ascending cyclonic whirl of air bends backward, it will tend to descend as an anticyclone. The alternation of lows and highs where storms travel across a continent and several other facts bear out this influence. Sunspots commonly occur in pairs that rotate in opposite directions, showing close analogy with our cyclones and anticyclones. But whereas our cyclones never reverse their polarity (or direction of rotation), sunspots reverse it about every 11.2 years.

The magnetic north pole of the sun lags behind the rotation of the photosphere, or moves relatively westward, as Hale has shown. Let this also be the case with the planets and let their magnetic fields be sufficiently powerful, and it follows that they must produce magnetic disturbances in the sun's atmosphere, by causing changes in the density of the free electrons in different parts of that atmosphere. These changes must be most pronounced when the magnetic axis of a planet points most nearly toward the sun, which will be oftener than the orbital period of the planet. This gives an explanation of the difference between Jupiter's orbital period of 11.86 years and the great sunspot period of 11.2 years.

I have found that Uranus produces a sunspot cycle of 81.15 years (its orbital period being 84 years), its last maximum being July, 1870. Uranus is far more powerful than Jupiter in its sunspot effect, probably because its rotative axis is so greatly inclined that its magnetic axis points much more directly at the sun than does that of Jupiter.

Uranus and Jupiter are two great sunspot generators, the latter being exceedingly important because of its relatively short cycle of 11.2 years. Its last well-established maximum sunspot effect was Aug. 12, 1917, or 1917.6; and I have counted backward from that date to establish the 11-yr. cycles in Table I. The last year of each of the cycles in that table is the year in which a Jupiter sunspot maximum effect occurred. This does not mean that there was invariably a maximum of spots in that year, for Uranus, Neptune and perhaps a trans-Neptunian planet at times submerged Jupiter's effect. It is noteworthy, however, that of the 28 recorded sunspot maxima from 1615 to 1917, 17 occurred within a year of the dates that I have assigned to Jupiter maxima, and that 6 others are fully explained by the Uranus and Neptune dates of maxima, leaving but 5 not explained with great precision.

Neither Jupiter nor Uranus produces a sunspot maximum oftener than once during an orbital revolution, which indicates that only one end of its magnetic axis is effective in causing sunspots.

The total number of spots in the sun's two hemispheres is seldom even approximately equal during any two successive 11-yr. periods. Prior to about 1850 the number of spots in the sun's northern hemisphere exceeded those in the southern hemisphere, but since then the contrary has been the case. If cyclonic storms are more numerous and intense the greater the preponderance of sunspots of south polarity and if the polarity reverses every 11.2 years, it follows that so long as there is a preponderance of sunspots in the sun's southern hemisphere, then there must tend to be alternate 11.2-yr. periods of wet and dry weather, provided only that the spots of the new cycle wax rapidly while those of the old cycle wane rapidly in number. Whether this order of waxing and waning occurs or not may be readily ascertained by comparing the average percentages of spots in the two hemispheres, thus:

Period	Per Cent N. Hemisphere
1874-84	43
1885-95	38
1896-06	48
1907-17	45
1918-28	56

The percentages above given are average annual percentages of spotted area (Greenwich data) deduced from a

table given by Clough in "Monthly Weather Review," July, 1928, p. 262. The alternate increase and decrease in percentage for the 11-yr. periods confirms the inference above made.

On the other hand if we take 11-yr. periods from minimum to minimum (instead of from maximum to maximum) of Jupiter sunspot effect, we get the following results:

Period	Per Cent N. Hemisphere
1880-90	38
1891-01	42
1902-12	42
1913-23	57

For the first three of these periods we have an almost exact equality of spotted area in the two hemispheres. Then follows a sudden marked increase, the duration of which is problematical.

In the light of the results shown in Table I, it is very clear that for many 11-yr. periods, there has been alternate rapid and slow growth of the Arizona pines, just as during the 5 cycles from 1874 to 1928 there was an alternation in the percentage of spotted area.

Study of Table I shows that there have been three times since 1403 when the cycles of wet and dry periods of 11 years reversed themselves, namely, the periods of 1515-25, 1638-48 and 1862-72. This indicates that about these times the percentages of sunspottedness in the sun's hemispheres reversed themselves. The earliest accurate records of percentages of spottedness in the two hemispheres are those of Carrington and Spoerer, which are given in Clough's article above mentioned, from 1854 to 1890. For the year 1854 there were 61 per cent of the total number of spots in the sun's northern hemisphere; in 1855 it had dropped to 49 per cent; in 1856 to 37 per cent and from 1856 to 1873, inclusive, it averaged 47 per cent. The data subsequent thereto, but using areas instead of numbers of spots, are given above. It appears, therefore, that about 1856 the spottedness of the sun became greater in its southern hemisphere; and it is to be noted that the 11-yr. cycle that followed this date is marked in Table I as one in which a reversal of cycle occurred. So the only quantitative record of change in relative spottedness in the two hemispheres agrees with the evidence of such a change as derived from the growth of the Arizona trees.

The date of the next reversal of cycle is problematical, for Table I shows two different lengths of time between reversals, namely, 123 years and 224 years.

The cause of the shifting of the majority of sunspots from one hemisphere to the other seems to be the positions of the slower-moving planets relative to the sun's equator.

Huntington (pp. 211 and 216) states that Stewart, Maunder and Pocock independently found that sunspots are either more numerous or larger on the sun's face that is more remote from Mercury, Venus and Earth. In his "Astronomy" (p. 35) Chambers says that Stewart (in his investigation of the effect of Venus) found that spots tend to break out on the face of the sun nearest Venus, but attain their maximum when they are on the face farthest from Venus. It follows, therefore, that a slow-moving planet having an orbit considerably inclined to the sun's equator would probably cause more sunspots north of the equator during one-half of its orbital period, and the converse during the second half. I am inclined to think that one or more unseen planets beyond Neptune are mainly responsible for the greater changes in the sunspot preponderance in the sun's two hemispheres.

If I have spoken with a good deal of assurance about the length and constancy of the Jupiter sunspot cycle, it is not merely because the data in Table I very strongly support such an inference.

Long before this table was prepared, I had found just as convincing evidence

Table I.—45 Periods of 11 Years' Growth of Arizona Pines Showing Alternating Cycles

11-Year Period	Average Yearly Growth m. m.	Theoretical Relative Rainfall	
1403-13	1.94	Wet	(Uranus peak, year 1384)
1414-24	1.40	Dry	
1425-35	1.41	Wet	
1436-46	1.05	Dry	
1447-57	1.25	Wet	
1459-69	1.19	Dry	(Uranus peak, year 1465)
1470-80	1.25	Wet	
1481-91	1.04	Dry	
1492-02	1.08	Wet	
1504-14	.90	Dry	
1515-25	.92	Dry	(Reversal of Cycle)
1526-36	1.18	Wet	
1537-47	1.22	Dry	(Uranus peak, year 1546)
1548-58	1.61	Wet	
1560-70	1.56*	Dry*	
1571-81	1.15*	Wet*	
1582-92	1.06	Dry	
1593-03	1.30	Wet	
1604-14	1.22	Dry	
1616-26	1.31	Wet	(Uranus peak, year 1626)
1627-37	0.79	Dry	
1638-48	0.79	Dry	(Reversal of Cycle)
1649-59	0.83	Wet	
1660-70	0.73	Dry	
1672-82	1.00	Wet	
1683-93	.90	Dry	
1794-04	1.04	Wet	
1705-15	1.05	Dry	(Uranus peak, year 1708)
1717-27	1.08	Wet	
1728-38	0.67	Dry	
1739-49	0.77	Wet	
1750-60	0.65	Dry	
1761-71	0.76	Wet	
1773-83	0.54	Dry	
1784-94	0.71	Wet	(Uranus peak, year 1789)
1795-05	0.63	Dry	
1806-16	0.61	Wet	
1817-27	0.49	Dry	
1829-39	0.67	Wet	
1840-50	0.49	Dry	
1851-61	0.70	Wet	(Uranus peak, year 1870)
1862-72	0.71	Wet	(Reversal of Cycle)
1873-83	0.46	Dry	
1885-95	0.43	Wet	
1896-06	0.40	Dry	

*Only 2 of the 45 periods fail to agree with the theory and this is one of the two.

Note: These annual tree-growths are averages deduced from a table given by Douglass for trees at Flagstaff, Arizona, without adjustment for a declining rate of growth with increasing age of trees. In determining the relative rainfall (whether "wet" or "dry"), the contrast should always be made between the 11-yr. periods that are close together; and if it is desired to ascertain whether a given 11-yr. period is "wet" or "dry" compared with the 11-yr. periods before and after, add the average annual rate of tree-growth immediately before the given 11-yr. cycle to the rate of immediate growth following, and divide by 2. If the quotient is a rate of growth in excess of that shown for the given 11-yr. cycle, then that cycle is relatively "dry."

of the stability of the Jupiter sunspot cycle. Take, for example, the fact above mentioned that by assigning a length of 11.2 years to the Jupiter cycle, 17 of the 27 known sunspot maxima from 1615 to 1917 fall within a year of the calculated Jupiter maximum period. Deduct 5 of the 27 known specks because they were caused by Neptune and Uranus, and there are left 22 of which 17 fall within a year of a calculated Jupiter maximum. Since the Jupiter cycle is 11.2 years; if a spot maximum occurs within 1 yr.., on one side or the other of a Jupiter maximum, we have $2 \div 11.2 = 0.18$, which is the probability ratio of its occurrence purely by accident, or about 1 chance in 5. That 17 of 22 such coincidences occurred could have happened purely by chance only once in 88,414,400 times.

Between the sunspot maxima of 1615.5 and 1917.6 there are 27 cycles of 11.19 years. It is admitted that Wolf's determination of the 1615.5 date is approximate. But fortunately there are two very early dates when very large sunspots were seen by the Benedictine monk Adelmus, namely, Mar. 17, 807, and May 28, 840. These dates are 33.195 years apart, or 3 cycles of 11.065 years, which is close to the Jupiter cycle as to leave little doubt that they were both near the times of a Jupiter sunspot peak. From Mar. 17, 807, to Aug. 12, 1917, is 1110.4 years. If 99 cycles intervene, they average 11.216 years; if 100 intervene, they average 11.104 years. So many other facts indicate that the cycle is about 11.2 years that the 11.216 is probably very nearly correct. If we divide the 1077.2 years between May 28, 840, and Aug. 12, 1917, by 96 we get 11.22 years. According to Chambers (p. 44) Hakluyt saw "a great black spotte" Dec. 7 to 16, 1590, or 326.3 years prior to Aug. 12, 1917, which divided by 29 is 11.248 years. It is significant that the Douglass table of Arizona (Flagstaff) pines shows an exceptionally great growth in 1589, only a year earlier than the Hakluyt observation; and the Douglass table of California sequoia growth likewise shows a peak in 1589. This last-named table furnishes many excellent opportunities to test the theory that there is a cycle of about 11.2 years. I will mention only 3 of scores of similar calculations that I have made, using the sequoia growth tables. In 1157 B. C. and again in 1146 B. C. (11 years later), there were extraordinarily great thicknesses of wood deposited in these trees. From 1157 B. C. to 1917 A. D. is 3074 years, or 274 cycles of 11.215 years. An exceptionally great growth occurred in 663 B. C., which is 2580 years prior to 1917 A. D., and 230 cycles make the average 11.217 years.

Table II gives the years of sunspot maxima as far back as sunspot counts have been accurately made. It also gives the dates that I have assigned to Jupiter's maximum sunspot effect, the Jupiter cycle being 11.21 years.

See an article in the October, 1929, issue of "Water Works and Sewerage," on Five Important Weather and Earthquake Cycles.

The table shows that for the last 8 sunspot maxima, there has been an alternation of high and low numbers of spots. During this period of 80 years, Jupiter has not been seriously interfered with by any planet, except when Uranus produced the peak of 1870.5. The previous peak period of Uranus in 1789 and that of Neptune in 1778 seriously interfered with Jupiter effects. In fact neither in 1783 nor in 1794 did Jupiter cause many sunspots, because of the effects of the magnetic fields of Neptune and Uranus upon Jupiter's field. Because their axes lie almost in the planes of their orbits Neptune and Uranus produce very powerful magnetic effects on the sun, Jupiter and earth.

Although Jupiter causes its maximum sunspot effect only once in 11.2 years, when its north magnetic pole points most directly sunward, it usually causes pronounced weather disturbances when its south magnetic pole (as well as its north magnetic pole) points most directly earthward.

I am inclined to think that sunspots change their polarity every 11.2 years, because there are two magnetic fields on the sun (corresponding to the two on the earth) which alternate in their control of the rotation of sunspots. If electrons are carried aloft as a result of the action of the lower field during one 11.2-year period, then the upper field is closer to the most highly electrified intermediate atmosphere of the sun, and during the succeeding 11.2 years the upper field gives rotation in an opposite direction to the sunspots and discharges streams of electrons back toward the lower fields. A similar effect could be secured by the periodic warping of the two fields under the magnetic attraction and repulsion of the sunspots.

If one of the two fields is stronger than the other, it follows that the 11.2-year sunspot peaks would alternate in intensity.

Sunspot Peak Year	Average Number of Sunspots	Date of Juipter's Max. Sunspot Effect	
1706	49	1704.6	
1718	50	1715.8	
1727	90	1727.0	
1739	85	1738.2	
1750	83	1749.4	
1761	85	1760.6

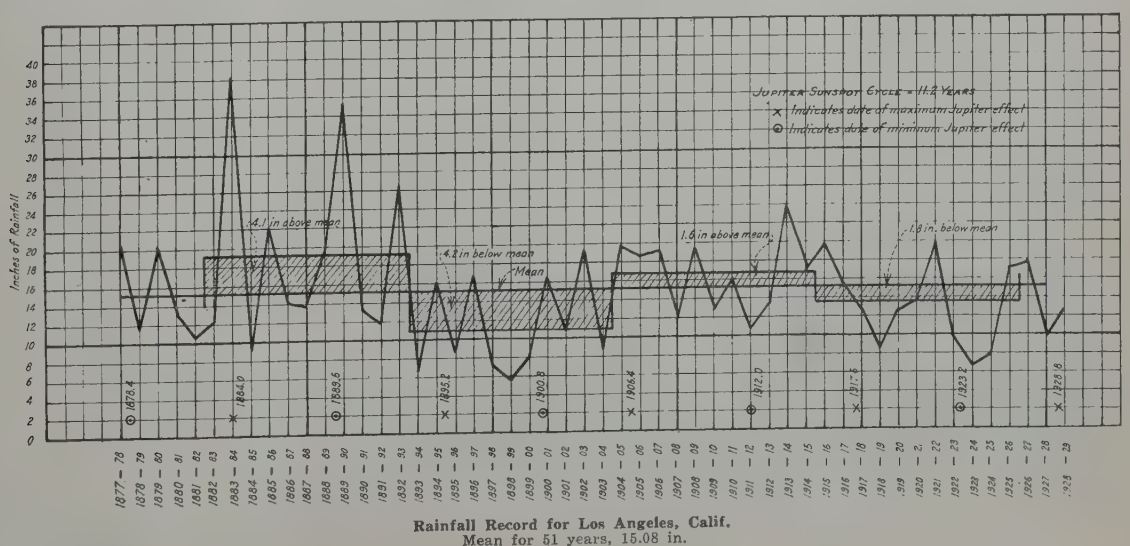
Note: The sunspot numbers prior to 1750 are those given by Fritz (Monthly Weather Review, October, 1928, contains a translation of his paper). The dates of Jupiter's maximum sunspot effect are based upon a sunspot period of 11.21 years deduced by the author. See "Water Works and Sewerage," October, 1929, for a discussion of Jupiter's cycle and those of 4 other planets.

Although the sequoia trees furnish a very long chronology of weather changes, a much longer one is to be found in Baron Gerard de Geer's clay varve charts, given in his great article, "On the Solar Curve as Dating the Ice Age, the New York Moraine and Niagara Falls," "Geografiska Annaler," 1926, H. 4. An English translation of this article was received from Baron de Geer (whose address is Sveavagan 32, Stockholm, Sweden), and its charts have enabled me to calculate the length of the Jupiter sunspot cycle with great precision. Baron de Geer had, of course, seen that there is a frequently recurring cycle of 11 years in the thickness in the clay varves, or layers of clay annually deposited in ancient glacial lakes. The zero year of his varve time scale is about 6800 B. C. From 1077 to 1580 on his time scale is 504 years, and there are peaks in his chart at those dates that are clearly peaks in an 11-yr. cycle; $504 \div 45 = 11.200$ years.

On his chart in the year 6975 of his scale there is a peak that is also clearly one of a series of 11-yr. peaks; hence, from 1077 to 6975 is 5,898 years which divided by 526 gives 11.213 years, and divided by 525 gives 11.234 years. Judging by the sunspot data and the tree-growth data, the proper division is 526. If so, Jupiter's sunspot cycle is very nearly 11.213 years.

This seems to be the acme of accuracy attainable at present until it is remembered that Baron de Geer has stated that he feels very sure that his zero year is within a century of being 6800 B. C. If so, it becomes possible to tie his clay varve chronology to our Christian chronology with accuracy, if we know quite closely two sunspot cycles. As above stated the Uranus spot cycle is very clearly marked both on the sunspot curve and on the tree growth curves. I had found it to be 81.15 years, its last peak being in July, 1870. Study of the clay varve chart indicated Uranus peaks in 1185 and 6784, to name only two extreme years that were clearly defined. Those years are 5,599 years apart, and 69 cycles, give 81.145 years as the Uranus cycle. Using this Uranus cycle and a Jupiter cycle of 11.214 years, I was able to show that de Geer's zero year is 6766 B. C., provided his 6806 B. C. estimate is within 200 years of the correct date.

Table I clearly shows the effects of 7 sunspot peaks due to Uranus; the first one in 1384 is foreshadowed in the great growth of 1403-13. The next one, in 1465, finds full expression, for although the decade of 1459-69 shows an average growth below that of the preceding and the following decades, that is because it lies in a dry period. If we take the 3 periods (11-yr.) that center around each of the 6 Uranus peaks of



Rainfall Record for Los Angeles, Calif.
Mean for 51 years, 15.08 in.

1465, 1546, 1626, 1708, and 1789, and 1870, and the 3 periods that center around each of the 6 Uranus valleys of 1425, 1506, 1586, 1668, 1749 and 1830, we find that there was 21 per cent greater tree growth during the 6 Uranus peak epochs (of 33 years each) than during the 6 Uranus valley epochs (of 33 years each); this calculation being based on data of growth equated for declining growth with increasing age, as per the Douglass chart. The six 11-yr. periods nearest a Uranus peak show a 29 per cent greater growth (equated) than do the six periods nearest a Uranus valley.

Douglass found that the tree growth at Prescott correlated with the rainfall at Flagstaff, 12 miles away, in 70 per cent of the year during which rainfall records had been kept. There is thus established a very satisfactory agreement between Arizona tree-growth and rainfall.

Earth Dam and Spillway, Mango, Ill., Impounding Reservoir on the Edgewood Cut-Off of the Illinois Central

Horseshoe Spillway Solves Problem of Limited Space

Among the many problems incidental to the building of the Edgewood cut-off of the Illinois Central System was the development of a complete water-supply system having a capacity adequate for the needs of future years. The line, which extends from Edgewood, Ill., to Fulton, Ky., has a length of 169 miles and the total annual volume of water required, estimated at 336,000,000 gal., was divided among eight water stations. Aside from the major aspects of the problem of obtaining a suitable supply, many of the details of the project furnished an outlet for the ingenuity of the designers.

One such instance occurred in connection with the Mango, Ill., supply station. Here the water station is supplied from a reservoir having a storage capacity of 109,000,000 gal. and covering an area of 33.8 acres. The total annual runoff draining into the reservoir is estimated at 125,880,000 gal., a quantity which is far in excess of the estimated maximum annual consumption of 40,000,000 gal. The water is impounded by an earth-fill dam, paved with concrete on the reservoir side to prevent erosion. The unusual feature of this dam is the spillway. Space was limited and, in order to secure a length of crest sufficient to care for the excess runoff, the spillway was built in the form of a horseshoe. Dam and spillway are shown in the accompanying illustrations. The spillway has a length of 88 ft. The dam is 523 ft. long and 30 ft. high, and contains 38,300 cu. yd. of earth. A concrete toe wall and a cut-off wall of Wakefield sheet piling are provided at the toe of the fill. The downstream slope is sodded.

Horseshoe Spillway of the Mango Dam. This Design Was Made Necessary by Limitations on the Space Available

The water development along the Edgewood line was under the direction of C. R. Knowles, Superintendent of Water Service for the Illinois Central.

Cleaning Rusty Pipes with Steam

Recent experiments in the removal of rust incrustations from steel pipe with steam are declared to have been successful. The pipe is filled with steam for about 15 minutes and then flushed with cold water, which carries away the loosened scale. These operations are repeated until flushing brings down no more of the oxide, indicating that the inside of the pipe is clean. Steam pressures from atmospheric up to 150 lb. per sq. in. have been used. Since a pipe treated in this manner must be free to expand throughout its length, the process apparently has a somewhat limited application.

This scheme was originated by C. W. Poulson, chief engineer of the Equitable Building in New York City. To date, about 2500 ft. of pipe have been cleaned in lengths varying from 250 to 500 ft.

Long Distance Transportation of Water

An Outline of the Main Factors to Be Considered, Particularly in the Solution of This Phase of the Water Supply Problem in the Semi-Arid Southwest

By E. A. BAYLEY

Assistant Engineer, Department of Water and Power, Los Angeles, Calif.

MANY important elements must be taken into consideration in making the preliminary investigations for the transportation of large quantities of water over long distances by means of an aqueduct system. Among these, may be mentioned.

1. The determination of the definite point of intake for the aqueduct and its location with relation to any initial storage which may be provided.
2. The location of its terminus and the minimum terminal storage required.
3. The character of the country which the aqueduct is to traverse.
4. The type of aqueduct suitable for the country through which it is to be built, and the material to be used in its construction.
5. The quantity of water to be transported.
6. Whether or not pumping along the route will be necessary.
7. The possibility of generating power along the aqueduct route.
8. The most suitable rates of gradient for its several parts.
9. The estimate of construction costs.

In the case of several routes being available, a comparison of the construction and operating costs of one route with another must be made, in order that the most economical one may be selected.

Location of Point of Intake.—In locating a definite point of intake for an aqueduct, there are two major factors —topographic and hydrographic—which enter into the problem. The topographic factor includes the elevation of the river itself, the possibilities for reservoir sites and the elevations of these sites with respect to the proposed aqueduct. The suitability of the intake for the elimination of silt and other suspended matter such as brush and trees often carried in flood flow, is also a topographic matter of importance.

A proper consideration of the hydrographic features shows that the intake should be placed where there is a certainty of obtaining an ample quantity of water at all times. If taken too far upstream, the requisite supply might not be available due to the small contributing drainage area above. On the other hand, if taken too far downstream, evaporation and seepage losses might increase at a greater rate than the gain from tributaries. This would reduce the stream flow and possibly affect the supply available.

Both the topographic and hydrographic features were given careful attention in locating the point of intake of the Los Angeles Owens River Aqueduct. From a topographic standpoint, the aqueduct had to be so located that water could be discharged into the city's Haiwee Reservoir on the divide between the Owens Lake Basin and the arm of the Mojave Desert known as Indian Wells Valley. From a hydrographic standpoint, it was deemed advisable to place the grade of the aqueduct sufficiently low that a gravity flow from some very large springs, known as Black Rock Springs, could enter the canal. These springs are located about 60 miles beyond the Haiwee Reservoir, and at a slightly higher elevation. With the grade fixed by the relative elevations of Haiwee and Black Rock Springs, the aqueduct location was prolonged northerly to an intersection with the Owens River, where a suitable intake was constructed.

The Colorado River in its lower reaches is situated at an elevation not greatly above sea level. Many cities of the coastal plain of Southern California to be supplied with water from this source, are relatively higher in elevation. Therefore, any intake in this portion of the river would require an aqueduct of a non-gravity type, that is, one through which the water is pumped over at least a part of its length. If a gravity aqueduct from the Colorado River is constructed, the intake would have to be placed far up the river in order to deliver water to the coastal cities.

Storage Requirements.—A liberal amount of terminal reservoir storage is needed when an aqueduct system is operating at its maximum capacity. The storage required by the city of Los Angeles to operate the Owens River Aqueduct system for the year 1928, is given as an example of relative amounts.

During that year, in caring for its domestic demand, approximately 7 per cent of the annual quantity of water transported, was stored during the winter months for use during the following summer. For irrigation in the San Fernando Valley within the city limits, about 40 per cent of the annual quantity used for this purpose had to be stored. In hillside home areas, roughly 17 per cent of the annual demand was likewise taken from storage. During the whole year, the total terminal storage required to provide for the combined domestic and irrigation demands on the Owens Valley Aqueduct system, was approximately 19 per cent of the entire quantity of water transported.

Storage facilities should be located as near the territory to be served as is practicable, and if possible at a higher elevation.

Character of Country to Be Traversed.—In order to determine the nature of the country through which an aqueduct is to pass, it is necessary to have accurate topographic information concerning the territory. If topographic maps of the Geological Survey are available, it is possible to get at once a general idea of the topography of the country to be traversed. If such maps are not yet made, it becomes necessary to make a detailed survey of the area. This topographic survey usually consists of the making of contour maps, showing a contour interval sufficient for the purpose at hand. These can be made either by the transit and stadia method or by the plane table method. In either method, a system of horizontal control must be installed prior to the actual mapping of the ground. If the transit and stadia method is used, the system of control is usually a chained traverse; while if the plane table method is adopted, triangulation is generally best. The plane table method is used by the United States Geological Survey in all of its mapping for the topographic atlas of the United States, and is also the one used on the Colorado River Aqueduct Project. The information gained from the contour maps, supplemented by field examinations, discloses the several kinds of structures of which the aqueduct will have to be constructed. Mountainous areas indicate that tunnels must be used; conduits or canals are the most suitable for level, plain or desert country; and deep canyons require inverted siphons as a part of the system.

In the case of the Colorado River Aqueduct Project, careful studies of the territory involved show that a complex situation of desert, mountain and valley topography exists. Much of the country through which construction work will have to be carried, is vast desert waste land scattered with rugged ranges acting as barriers. There is, however, a stretch of territory near the western end of the proposed aqueduct which is highly cultivated, where orange groves and vineyards abound. This illustrates that there are many complicated problems which must be solved in the lo-

cating of an aqueduct with relation to the varied topographic conditions.

Type of Aqueduct Construction.—Aqueducts have been constructed of stone, wood, brick, concrete and other materials. The most recently constructed aqueducts have been built mainly of concrete. Where valleys intervene, either reinforced concrete or steel inverted siphons have been used. Tunnels are usually lined with concrete, though this lining is sometimes omitted where the rock is exceptionally firm.

The most suitable type of aqueduct for desert country which is subject to cloudbursts, is probably one that is covered, except in the case of inverted siphons, constructed wholly of concrete, and buried throughout its length. This permits torrential surface flows to pass over the aqueduct without damage to its structure. Modern practice varies in the case of inverted siphons of steel or iron. Some have been buried throughout their length, while others have been supported on piers where they may be inspected and repaired from time to time. The latter case is equally satisfactory with respect to cloudburst conditions.

In the case of Catskill Aqueduct for the New York water supply, a type known as "cut and cover" was built. It is constructed of concrete, horseshoe in shape, and only partially buried. The excavated material was used to make the embankment over the structure. While this type of aqueduct is no doubt suitable for Eastern conditions, it is obvious that on our Western deserts, where no definite stream channels exist, and any section of the desert may be subject to extreme erosion from torrential floods, the better practice would be to bury the aqueduct throughout.

Quantity of Water Transported.—In designing an aqueduct to carry an exceptionally large quantity of water, it is necessary to exercise unusual care in determining its correct cross-sectional dimensions. It must have the best hydraulic properties consistent with good constructional design. The construction quantities per unit of length should be a minimum and still obtain an enduring structure. The subject of hydraulic design must be carefully considered in order that the aqueduct when completed and placed in operation will have the required capacity. When properly designed, the flow should closely approximate the theoretical flow indicated by the formulas used.

The amount of water which can be transported in an aqueduct, is dependent upon its velocity. There are various formulas for the computation of the velocity of flow in conduits, canals, tunnels, inverted siphons, flumes, force mains and penstocks such as make up a complete aqueduct system. These formulas are largely based upon experimental data found to exist in other similar structures. Formulas derived by Ganguillet and Kutter, Williams and Hazen, Scobey and others, give satisfactory results. Likewise, good results can be obtained from other exponential formulas derived from the known flows of constructed aqueducts similar to the one proposed.

In the design of the Los Angeles Aqueduct from the Owens River, the Board of Consulting Engineers who reviewed the plans in December, 1906, suggester the use of the Kutter formula with a value of "n"=0.014 for the design of covered concrete conduits, and the Chezy formula with a value of "C" = 90 for riveted steel pipe lines. Since that time, a number of large conduits and pipe lines, notably those of the Catskill and our own Los Angeles Aqueduct, have been built, and numerous measurements of the actual flow in such conduits have been made. Careful examination of these experiments lead to the valuable conclusions as to the best formulas to adopt in the design of any large aqueduct. In applying such formulas, engineers generally use conservative factors. However, the use of factors which are too conservative, in order to insure the rated capacity, may result in far greater cost than necessary.

Necessity for Pumping.—The ideal method of transporting water long distances is by means of a gravity aqueduct, or one which is constructed on a continuous down-grade from its intake to its terminal point. However, in cases where a gravity aqueduct cannot be built within economic limits of cost, pumping must be resorted to, and a non-gravity aqueduct constructed. In such a case, in order to pump the water economically, ample power available at a low cost is indispensable.

The idea of a gravity aqueduct has an appeal to the popular mind, due largely to prejudice brought down from the past. When pumping plants were small and machinery unreliable, there was a lack of dependability in pumping projects. Additional sums were then properly spent to assure a supply by means of gravity, as pumping methods proved unsatisfactory. All this is now changed. This is a mechanical age, and machines have been perfected so they are about the most dependable things in existence. A pump is little more subject to derangement than a tunnel.

Generating Power.—In the building of any aqueduct, gravity or non-gravity, topographic conditions along the route sometimes make feasible the generation of power. The value of power, increasing year by year, justifies a very careful study of the location of an aqueduct to determine this possibility, and may warrant an additional expenditure to obtain it. If the estimated cost of construction, then, is found to be less than the warranted expenditure, the power plants should be built and operated.

In the building of Owens River Aqueduct, the City of Los Angeles took advantage of the difference in elevation between the Fairmont Reservoir and the Lower San Fernando Reservoir for the generation of power. The city has built three large power plants along this section of the aqueduct. These have been operated for a number of years and the net revenue derived from them has more than warranted their construction.

Along the proposed Colorado River Aqueduct, there is also a possibility of generating some return power near its western terminus. Whether this possibility is economically feasible or not depends upon the result of studies now in progress by the Department of Water and Power of this city.

Most Suitable Gradient.—The cost of constructing any aqueduct is largely dependent upon the hydraulic grade used. Any change in gradient will have its effect on the velocity of the water in the conduit. By flattening the slope, the velocity will be reduced and the cross sectional dimensions must be correspondingly increased in order that the carrying capacity will be unaltered. Conversely, by steepening the grade, the velocity will be increased, and the cross-sectional area can be similarly reduced.

When the points of intake and delivery are fixed, it is often possible to obtain the minimum total cost by balancing the gradients between the several types of structures which vary greatly in cost. In this case, the minimum cost is obtained when the gradients are so established that a change in any one affecting its cost will produce an equal and opposite change in the cost of any other.

It is usually considered sufficiently accurate to balance grades graphically. Curves are plotted showing costs in relation to head, for the various sections of the aqueduct under construction. If tangents are drawn to these curves in such a way that the sum of the heads to be consumed is equal to the total available head, the sum of the costs will be a minimum. Dividing the resulting head for each section by its linear length will give the proper gradient for that section. The results are, of course, subject to limitations in that balancing the gradients must not affect the aqueduct location sufficiently to place it in ground more difficult of construction.

In the location of the Los Angeles Owens Valley Aqueduct, the method of balancing grades outlined was used with considerable success. Between Haiwee and Fairmont, a distance of 135 miles, the saving shown between the estimated cost of the aqueduct having balanced grades and that of one without balanced grades, was considerable.

Where an aqueduct is designed with pumping plants along the line, any change in the hydraulic gradient will effect a change in the head pumped against, and consequently will alter the cost of operating the pumps. The cost of pumping is also dependent upon the demand for water by the consumers.

Therefore, in such a non-gravity aqueduct, the cost of pumping must be balanced against interest and other charges on the cost of construction. This balancing of operating costs against interest and other charges for construction must be studied carefully in order to arrive at the most economical combination of grades and lifts. Due to these variable factors, the estimated capital investment in a non-gravity aqueduct may vary within wide limits.

Estimating Construction Costs.—In long distance transportation of water, the product transported is generally delivered to the user at a price which, if computed on the basis of a price per ton, would be but a few cents as against many dollars for all other commodities. In order to accomplish this remarkable feat, the cost of construction to be carefully estimated, and in actual construction, must be kept within reasonable bounds. A difficulty is found in making comparisons, in the lack of finished works of large size, which can be used for guides as to costs. This is particularly so for projects built within the last decade, when labor and material cost have advanced so rapidly. Study must be made of the laws enacted within recent years bearing on compensation and hours of labor, camp sanitation, safety and other similar matters, all of which must be considered in making estimates. The greater use of mechanical equipment offsets to some extent the higher cost of labor, and there must be careful balancing between the greater use of machinery and manual labor. In preparing an estimate, it becomes necessary to analyze each piece of construction and develop costs step by step, taking care that no essential element is omitted. Certain assumptions must be made, and there the designer has to draw upon all available information and decide according to his best judgment as to what plan of operation should be used.

In considering the relative costs of conduit and tunnel, it will be found in ordinary construction for equal capacities, that the cost of tunnel will be about double that of conduit. In general, the items making the total cost may be expressed in terms of labor, material and equipment, freight and hauling, energy and general expenses such as roads and trails, water supply for construction, camp sanitation, hospital and first aid and communication.

Acknowledgment.—The foregoing is an abstract of a paper presented before the Water Supply Section in the Short Course in Public Administration held June 17 to 21 at the University of Southern California.

Household Leakage.—An inspection by employees of the Water Board of Cambridge, Mass., during the past year located the following leaks:

On basins	171
On bath tubs	142
On set tubs	78
On faucets	2,198
On toilets	1,402

Gate Valves and Fire Hydrants

Notes on Their Maintenance and Operation

By CARL A. HECHMER
Department Engineer, Washington Suburban Sanitary District, Hyattsville, Md.

IT IS surprising, especially in small towns and villages, how little attention is given the maintenance of gate valves and fire hydrants on their water systems. The need of good engineering advice and design is recognized and is compulsory in almost every state. Practically every state health department has a law compelling the submission of plans for approval before a water system can be built. The question of good materials is also generally given the utmost consideration and the best valves and hydrants obtainable, in the judgment of those in charge, are purchased and put into the water system. In many instances they are promptly forgotten until an emergency arises and quick, sure operation is necessary. Unless valves and hydrants are given regular attention and properly maintained, the water works superintendent has no assurance that they will function properly. This fact applies to any make of valve or hydrant or to any other mechanical device or piece of machinery. Unfairly the failure reflects on the designing engineer or the manufacturer of the material and the local department is given a clean bill of health.

Valves.—All valves on a water distribution system should be inspected once each year. This is the minimum requirement of the Fire Underwriters' Association. However, semi-annual inspection is advisable, if finances will allow it. Not only will the mechanical condition of the valve be assured, but valve boxes covered by paving material or earth will be located and reset ready for immediate operation in emergency. This is especially true in rural and suburban sections with a large percentage of unpaved streets. When a large leak occurs, excitement prevails and considerable time may be lost locating a valve box. Occasionally a large stone or stones are found down in valve boxes and these conditions are revealed on inspection and removed. In case the valve has to be dug up, uncovering the valve, it is advisable to install new packing in the packing gland which will prevent digging it up for a repacking for a long time. Always repack a valve when it is uncovered for any repairs. Packing is cheap and easily installed while the valve is exposed. To dig up a valve just to stop a packing leak is an expensive operation. Inspection also brings out valves which were carelessly or accidently left closed. Any water distribution system is weakened by gate valves being closed when they should be open.

How a Valve Inspection Should Be Made.—In addition to the box inspection, a valve inspection should proceed as follows: First set the valve key on the valve nut preparatory to turning the stem. Pour a small quantity of kerosene or diluted automobile crankcase drainings down the valve key stem. The oil will run down the key to the operating nut, thence to the valve stem and lubricate the valve stem against the packing gland. Finding its way into the packing gland, the packing will be softened and revived. Then operate the valve up and down several times, bringing the gate down into the groove hard each time and then opening the valve about one-quarter way. Valve troubles, preventing complete shut down, are usually caused by the accumulation of sediment under the seat. Each time the gate is pushed down into the groove a small portion of this sediment is pushed out the sides. The high velocity of the water through the partly opened valve removes what is pushed out and the operation is repeated until the groove is sufficiently cleaned to allow the gate to seat properly. This procedure is especially recommended when valves fail to hold when attempting a shut down. Of course, if the groove is filled with large stones or jointing material, the valve must be dug up and taken apart for repairs. The writer once operated a 16-in. valve up and down thirty times and secured a perfectly tight shut down. The valve had not been operated for a long time, having been declared worn out, since it always allowed a large volume of water to pass with the gate turned down hard with levers on the key.

In operating the valve a check should be made of the number of turns on the stem. Generally for the same size and make of valve the number of turns to close or open the valve completely is the same and a check can be made to see if the stem is bent preventing the valve from completely closing or opening. Either condition should be corrected, as partly open valves weaken the system and, obviously, partly closed valves will not shut off the water.

If the valve stem can be turned around and around with no apparent effect on the gate, the stem is broken and must be repaired.

Geared valves, usually set in manholes, must be given special attention on inspection. The gears should be cleaned with a wire brush and greased with a light clinging grease. The stuffing box should, of course, be examined and by the by-pass valve should receive the same attention as the smaller valves on the distribution system.

Fire Hydrants.—Proper care in the installation of a fire hydrant is necessary and makes maintenance less expensive. Proper drainage of the hydrant barrel after the main valve is closed is essential to prevent freezing of the hydrant in northern climates. The best method is to provide a bed of crushed stone or gravel around the bottom of the hydrant. The amount of stone necessary is dependent on the nature of the soil. In loose sandy soils a much smaller drainage bed can be provided than in a clay soil that absorbs water very slowly. A safe margin is to provide sufficient area to allow the drainage of an amount of water equal to twice the contents of the hydrant barrel. Connections are often made direct from the hydrant drain valve to the sewer. However, there are two serious objections, first the cost and second the direct connection between a sewerage system and a domestic water supply, even though the possibility of contamination reaching the water in the mains is remote. Generally water mains are laid on one side of the street and sewers on the other. Hydrants are installed at the curb on the same side as the water mains to shorten the length of the lead. To connect each hydrant drain across the street to the sewer would prove much more expensive than providing a stone drainage bed.

Fire hydrants must be inspected at least twice each year, in the spring and fall. Four inspections annually should be made, if possible, and this number of inspections is advocated by the Fire Underwriters' Association. In high value districts, weekly inspections are often made during extremely cold weather. Arrangements should be made between the water department, the fire department and any other possible users of hydrants to report to the water department immediately after using a hydrant during freezing weather and an immediate inspection made to insure the good condition of the hydrant. Use of hydrants by private individuals or contractors should be allowed only by special permit and the daily charge made high enough to permit daily inspection during freezing weather. During mild weather the inspection charge can be reduced as weekly inspections are sufficient.

Valuable data may be secured by the fire hydrant inspection by measuring the static pressure, the residual pressure with one nozzle open and the flow of water from the hydrant. Weak points on the distribution system can thus be determined and improvements due to new installation readily noted. System weakness due to unknown closed valves is also discovered and can be corrected.

Procedure for Making a Hydrant Inspection.—The following procedure is suggested for making a hydrant inspection:

First make a physical examination of the hydrant, noting the condition of the operating nut, the nozzle caps and chains and the general appearance of the hydrant. Then listen for leakage with an aquaphone placed on the operating nut. Then with the nozzle caps on tight open the hydrant valve. If static pressure readings are to be taken replace one of the nozzle caps with one connected to a pressure gauge. Note if all the nozzles are tight in the hydrant and whether the drain valve has closed properly. If the drain valve has not closed water will appear around the barrel of the hydrant on the outside. Then close the main hydrant valve and take off one of the nozzle caps. Observe the rate of drainage of the barrel to determine whether any obstruction has entered the drain valve. To clean the drain valve replace the nozzle cap and crack the main valve. As it requires about three full turns open on the main valve to completely close the drain valve on most makes of fire hydrants, the latter is still open on two turns. The full pressure of the water in the hydrant generally will push out any obstruction in the drain hole and the jet effect of the water through the hole will cut away the stone or earth which has packed around the outside. This simple remedy will eliminate the necessity of digging up the hydrant in most cases to correct drainage troubles.

With one nozzle cap off open the hydrant and thoroughly flush out the water in the lead. At this time the observation of residual pressure and rate of flow should be made. Then close down the hydrant slowly. If the hydrant fails to close off entirely, the trouble is probably being caused by an obstruction under the main valve. Do not put extra leverage on the hydrant wrench, but open the hydrant up again and then close it, repeating the operation several times. Do not attempt to close down beyond the point where the obstruction prevents the main valve from seating properly, as the obstruction will become embedded in the main valve and cannot be flushed off, or the valve seat will be damaged. Both valve and valve seat are damaged by attempts to force closing against obstructions. Foreign matter can generally be dislodged by flushing and it is then not necessary to dismantle the hydrant.

After the hydrant is closed and the rate of drainage checked, the stem should be oiled and the nozzles greased with a graphite grease. This kind of grease will not wash off and it prevents the nozzle caps from sticking.

Inspection Records.—Record of the inspection should be kept on a field sheet. The location of the hydrants to be inspected can be entered on the sheet in the office. These will allow correct routing and prevent skipping any hydrants. The information on the field inspection sheets can then be transferred to a permanent record card in the office. A card should be in the file for each hydrant, stating the size, make of hydrant and information regarding pressure at the hydrant. The date of each inspection should be entered on the card together with the observed pressures and rate of flow. Necessary repairs and their costs can also be recorded on the card and a history of each individual hydrant is easily obtained.

For quick reference the following is suggested: Use a map of the water system mounted on wall board with a push pin to denote the location of each hydrant. The color of the pin can show the condition of the hydrant as reported daily by the hydrant inspectors and the repair foreman. Use a blue pin for a hydrant in good condition, a black pin for a hydrant in need of minor repairs but not out of service, and a red pin for a hydrant out of service. Then when an inspector reports a hydrant out of service it is possible to tell at a glance whether the hydrants around it are in good condition. If several makes of hydrants are in use it is an advantage to know the make of hydrant before sending out a repair gang so the proper parts can be carried along. By using a small round colored disc under each push pin it is possible to determine at a glance the make of each hydrant, a different color being used for each make of hydrant.

For the sake of appearance and to protect the metal, hydrants, should be painted once every two years and if possible annually. Use a good grade of paint and care should be exercised to prevent getting paint on the nozzle threads or operating nut. The grooves on the nozzle caps which hold the chain links must be thoroughly brushed out as excess paint will harden and retard the fire department in removing the nozzle caps to connect fire hose.

Acknowledgment—The foregoing is taken from the July Journal of the American Water Works Association.

National Parks Cover 12,113 Miles.—In the last year the area of the national park system has been enlarged to 12,113 square miles, an increase of nearly 200 square miles, through the addition of lands to existing parks and the establishment of new ones, according to the records of the Department of the Interior. The greater portion of the new territory was added through legislation enacted at the second session of the Seventieth Congress. An area of about three square miles of spectacular scenic beauty was recently added to the Acadia National Park on the coast of Maine through the acceptance by the Secretary of the Interior of deeds covering this land.

Financing the Operation of Sewage Disposal Plants

A Discussion of Sewer Service Charge or Sewer Rental Charges Plans

By N. T. VEACH, JR.
Black & Veatch, Consulting Engineers, Kansas City, Mo.

IT is possible that every plant operator and city official in cities having a sewage disposal plant, is interested in its proper operation, even though at times from outward appearances at least, his interest may seem to be dormant. He, she or they, as the case may be, may be ever so interested, and still be unable to do anything about it. While it is true that there is at present a decidedly awakened "sanitary conscience" on the part of the public generally in connection with municipal sanitation, the fact remains that taken by and large the sewage disposal plants throughout the country hold a position somewhat like that of an unwelcome orphaned child. Some acquaintance with them is necessary, but it is not to be cultivated. The country is literally covered with disposal plants not giving results easily obtained with just a reasonable amount of maintenance and operation. In many cases, the stream or water courses into which the effluents from the plants discharge, is in no better condition than before the plant was installed. The expenditures for sewage disposal plants throughout the country run into many millions of dollars, which means a tremendous economic waste if they are not properly maintained and operated. There is probably no other line of endeavor either public or private where vast sums are expended, and then allowed to go without attention or maintenance, let alone operation. What is the matter with sewage disposal?

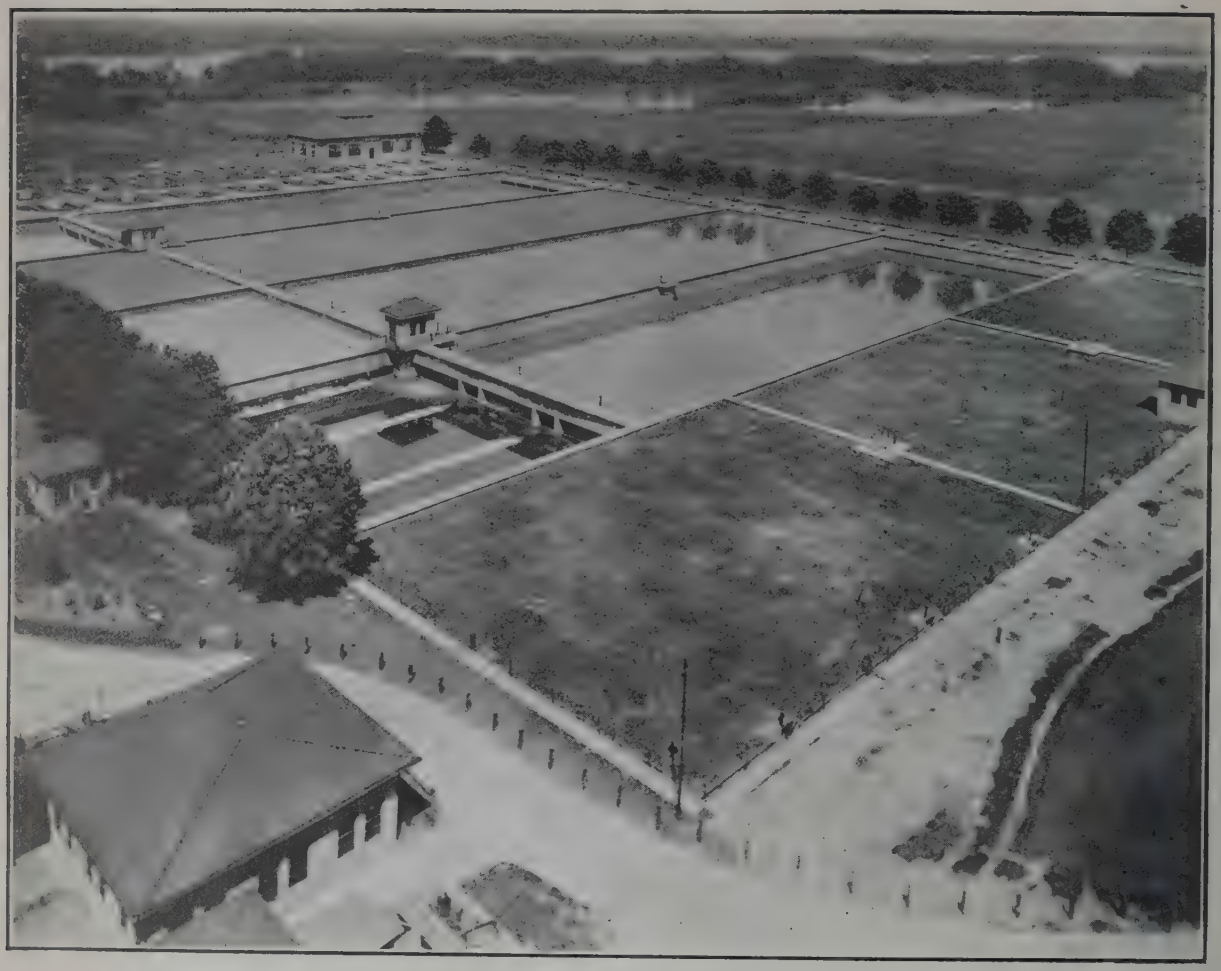
Contributing Causes for Neglect of Sewage Disposal Works.—There are several contributing causes for the general feeling of apathy toward the average disposal plant. Quite a number have been installed under orders from state boards of health, in order to protect water supplies or prevent nuisances. Others have been built on account of threatened or actual damage suits filed by owners over or through whose land the effluent is discharged. In either of these cases the plant is forced upon the city, and is not built on account of any real desire on the city's part to clean up pollution or nuisance caused by its wastes. Such conditions do not create a sympathetic feeling at least on the part of the public at large. It is interesting to note here, that in practically every case where the public interest is aroused, even though perhaps selfishly, excellent operation and maintenance is usually obtained. Reference is made to cities where lack of proper operation would effect those same cities, such as the ones along the Great Lakes, where effluents discharge into waters used for water supply; where sewer outlets are upstream from water intakes; or where effluents flow through the city, etc. Improper design is perhaps another contributing cause for neglect of plants. While sewage disposal is one branch of sanitary science that calls for the highest skill and knowledge to obtain proper design for each problem, and undoubtedly a large number of plants do not reflect engineering excellence, it is doubtful if poor design can be justly used as an excuse for poor or no operation. It is probable that the great majority of plants with improper design, could with technical guidance in operation, be made to function at least satisfactorily. This of course excludes plants that are heavily overloaded, or that have gotten into such a state of repair that operation is impossible.

Lack of Funds Handicap to Proper Operation.—The factors mentioned above as effecting operation of sewage disposal plants adversely are only contributory. There is one outstanding and in fact universal handicap to proper operation, i. e., lack of funds. The plants themselves are built with funds raised by bond issues or by special assessments, but generally speaking no arrangements are made for financing the maintenance and operation. Of course, every city has its "General Fund" to fall back upon, but it is the rule rather than the exception that this fund is already carrying all the burden possible. In some states the amount that can be raised by general taxation is limited by statute, and back of that is the usual desire on the part of the city officials to reduce rather than increase taxes, a very worthy and proper desire when it can be done.

The urban population is increasing steadily and practically and all cities are increasing in size each year. Additional demands are constantly being made for more and better municipal service, such as water, light, garbage removal, sewerage, etc. It is indeed a fortunate group of city officials that can keep taxes from raising, let alone reduce them, assuming of course that extravagance and waste is not practiced. Therefore, it is perhaps natural that the need of funds for operation of sewage disposal plants has been shoved into the background. It is the purpose of this paper to discuss a means of solving this financial embarrassment in which the sewage disposal industry finds itself.

Financing Sewer Rental Charges.—The plan has been styled "Sewer Service Charges" or "Sewer Rental Charges" and is in actual operation in at least two states, namely Ohio and Michigan, and is being considered seriously by health authorities in many of the other states. The plan is made possible by an enactment of the state legislature, authorizing cities having sewerage, sewage disposal plants, etc., or contemplating acquiring or building any or all of such improvements, to levy a service charge against all property connected to the system. In the two states mentioned, the statutes give the governmental authorities great power in assessing and collecting these service charges or rentals. Attention is called here to the two statutes mentioned, copies of which are given elsewhere in this article. The statutes authorize the governing bodies of municipalities to assess a sewer service or rental charge, and gives the power to collect such charges in the same manner as other taxes. The assessment can be levied along with the other taxes if desired. The Michigan statute has been amended several times, the copy given herewith being the present law. It goes somewhat further than the Ohio law, in that it authorizes the issuance of bonds for construction purposes in excess of the amount authorized by statute and includes garbage as well as sewage. In other words, there is no limit for such issues, but the bonds are not a direct obligation on the city. The bonds would be similar in character to the "Utility Bonds" that are authorized in some states. With such bonds, the property mortgaged is the sewers and disposal plant only. The purpose of this law no doubt was to give financing power to cities already bonded to the legal limit, and to small cities where the amount that could be raised under statute would be insufficient. It is questionable whether it would not be better to authorize additional bonding power for sewers and sewage disposal, issuing general obligation bonds, as their market value would be higher than the so-called "Utility Bonds," and thereby give a more economical means of financing. At any rate, quite a number of cities in each of the above mentioned states have enacted ordinances establishing schedules or rental charges, and have or will have funds to properly operate and maintain their disposal plants.

It seems that there can be little question about the desirability of having laws passed in all states, making the charging of sewer rentals possible.



Tanks and Sludge Beds at Back River Plant, Baltimore, Md.

Plants that are now neglected because of lack of funds, could be given proper attention. It is also probable that sewage disposal and general sanitation will receive more consideration, as the importance and need of such improvements will be constantly brought to the attention of the public, by the potent means of a bill for rental. The system of charging for service rendered will put sewage disposal, garbage collection and disposal, and other sanitary measures on the same general plane of respectability as other public utilities.

Rental Details Left to Governing Body.—The Sewer Rental laws in Ohio and Michigan leave the details of the rental charges to the governing body in each particular case, with the exception of privately owned systems in Michigan, which is wise. Rental charges for privately owned systems in Michigan are to be determined by the Public Utility Commission. The question of what rentals to charge is one that will require considerable thought and study in each particular case. Most of the charges that have been established so far are based on the amount of water consumption. This is probably a fair basis in small cities where the sewage is strictly domestic. In larger cities, especially those having a number of industrial plants, the situation is different. Here some industries may have a large water consumption and still contribute a small amount of sewage, also two industries may contribute the same amount of sewage with the sewage from one being four or five times stronger than the other. Also, certain industrial wastes may have a very destructive effect on sewers and operation of the disposal plant due to chemicals. It is possible that the use of water consumption data, tempered by a study of the bio-chemical oxygen demand of the different industrial wastes will give a fair basis for establishing rentals. As stated, the question of proper rentals will require considerable study, as most cities are urging industries to come to them, and great care will have to be exercised to avoid discrimination between the "wet and the dry" industries, although it is probably just that a wet industry contributing a difficult sewage to purify should include an extra item in production costs to cover its disposal. With properly adjusted rates it will be possible to obtain enough revenue to properly operate and maintain any disposal plant, without imposing a hardship on any one. In fact, the rentals required, compared with other utilities, will be in most cases ridiculously small.

Operators or city officials can render a real service to their cities, and to health and sanitation in general by using their influence in the passage of a sewer rental law in their respective states. There should be no legal limits to bonding power of any city for the construction of necessary sanitary works, and the raising of funds for their maintenance and operation.

MICHIGAN STATUTE

STATE OF MICHIGAN, 55TH LEGISLATURE
REGULAR SESSION OF 1929
Senate Bill No. 329 (File No. 350)
Introduced by Senator Woodruff
SENATE ENROLLED ACT No. 99
Ordered to be known as the Dykstra Act

An act to amend the title and sections one, two, three, four, five, six, seven, eight, nine and ten of act number three hundred twenty of the Public acts of nineteen hundred twenty-seven, entitled "An act authorizing cities and villages to provide a sanitary means of disposing of the sewage and night soil thereof; to charge owners or occupants of premises therefor; to raise money and issue bonds to erect and maintain sewage disposal plants, and to repeal act number two of Extra Session of nineteen hundred

twenty-six, and any other acts or parts of acts inconsistent herewith," and to add three new sections to said act to be known as sections twelve, thirteen and fourteen.

The People of the State of Michigan enact:

Section 1. The title and sections one, two, three, four, five, six, seven, eight, nine and ten of act number three hundred twenty of the Public Acts of nineteen hundred twenty-seven, entitled "An act authorizing cities and villages to provide a sanitary means of disposing of the sewage and night soil thereof; to charge owners or occupants of premises therefor; to raise money and issue bonds to erect and maintain sewage disposal plants, and to repeal act number two of Extra Session of nineteen hundred twenty-six, and any other acts or parts of acts inconsistent herewith," are hereby amended, and three new sections are hereby added to said act, said amended title and sections and added sections to read as follows:

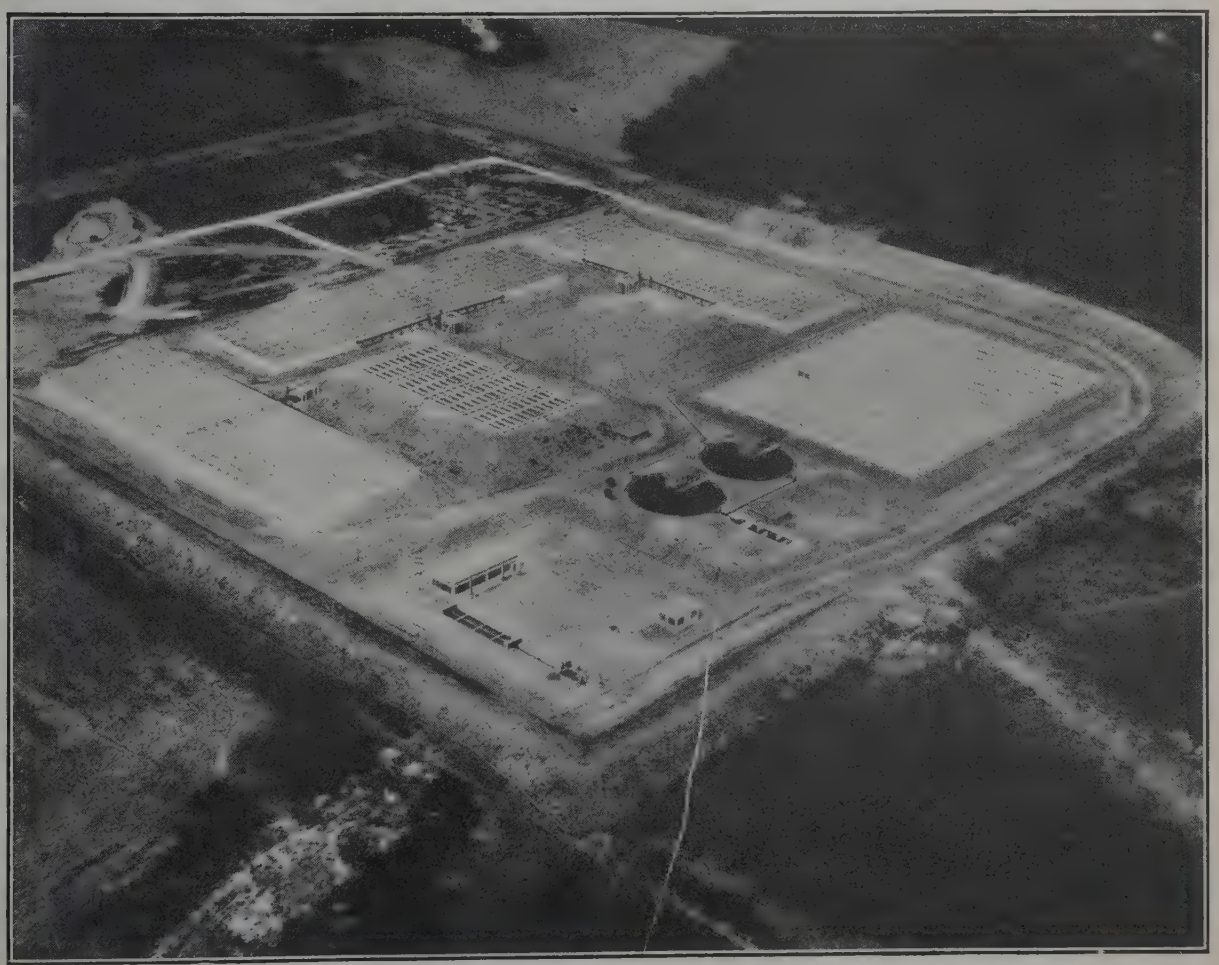
TITLE

An act authorizing counties, cities and villages, either individually or jointly by agreement, to provide a sanitary means of disposing of the garbage, sewage and night soil thereof; to charge owners or occupants of premises therefor; to borrow money and issue bonds to own, acquire, construct, equip, operate and maintain intercepting sewers and sewage disposal plants, and garbage disposal plants, and to repeal act number two of the Extra Session of nineteen hundred twenty-six, and any other acts or parts of acts inconsistent herewith.

Section 1. Any county, city or village in this State, either individually or jointly by agreement, is hereby authorized to own, acquire, construct, equip, operate and maintain either within or without the statutory or corporate limits of such governmental agencies or municipalities, intercepting sewers, including pumping stations, a plant or plants for the treatment, purification and disposal in a sanitary manner, approved by the State Department of Health, of the liquid and solid wastes, sewage and night soil and garbage of such governmental agencies and municipalities. They shall have authority to acquire by gift, grant, purchase or condemnation necessary lands therefor, either within without the statutory or corporate limits of such governmental agencies or municipalities. For the purpose of acquiring property for the uses herein mentioned such governmental agencies or municipalities may invoke and shall have all the rights, powers and privileges granted to "public corporations" under the provisions of act number one hundred forty-nine of the Public Acts of nineteen hundred eleven, being sections three hundred fifty-three to three hundred seventy-three inclusive of the Compiled Laws of nineteen hundred fifteen as amended, and which shall be in addition to any powers granted by such governmental agencies by statute or municipalities by their charters.

Section. 2. Such intercepting sewers, pumping stations, sewage disposal plant and system, and garbage disposal plant and system, shall be considered a public utility within the meaning of any constitutional or statutory provision for the purpose of acquiring, purchasing, owning, operating, constructing, equipping and maintaining such intercepting sewers, pumping stations, sewage disposal plant and system, and garbage disposal plant and system. Governmental agencies or municipalities may issue faith and credit bonds or mortgage bonds therefor beyond the general limits of the bonded indebtedness prescribed by law except as hereinafter provided. Such mortgage bonds as provided in this section shall not impose any general liability upon the governmental agencies or municipalities but shall be secured only on the property and revenues as hereinafter provided of such utility including a franchise, stating the terms upon which, in case of foreclosure, the purchaser may operate the same, which franchise shall in no case extend for a longer period than twenty years from the date of the sale thereof on foreclosure. Such mortgage bonds shall be sold for not less than par, bear interest at a rate not to exceed six per cent per annum, and the total amount thereof shall not exceed sixty per cent of the original cost of the utility except as hereinafter provided. No bonds shall be issued as general obligations of the governmental agencies or municipalities except upon a three-fifths affirmative vote of the qualified electors of such governmental agencies or municipalities and except as hereinafter provided, not in excess of three per cent of the assessed valuation of the real and personal property of such governmental agencies or municipalities as shown by the last preceding tax roll. No bonds shall be issued as faith and credit bonds or mortgaged bonds of the utility except upon a three-fifths affirmative vote of the legislative body of such governmental agency or municipality.

Section 3. The legislative body of any such governmental agency or municipality or the respective legislative bodies of such governmental agencies and municipalities, who may have agreed to jointly own and operate intercepting sewers or sewage treatment plants, may create a separate board or may designate certain officials of the governmental agencies or municipalities, to have the supervision and control of such intercepting sewers or sewage and garbage disposal plants. The legislative body, respective legislative bodies, or such board may make all necessary rules and regulations governing the use, operation, and control thereof. The legislative body or respective legislative bodies may establish just and equitable rates or charges to be paid to them for the use of such disposal plant and system by each person, firm or corporation whose premises are served thereby. If the service charge so established is not paid when due, such sum may be recovered by the governmental agencies or municipalities in an action of assumpsit, or it may be certified to the tax assessor and assessed against the premises served, and collected or returned in the same manner as other county or municipal taxes are certified, assessed, collected and returned.



Aerial Photograph of Sewage Disposal Plant, Fort Worth, Tex.

Section. 4. Bonds which are issued and secured by a mortgage on the utility as hereinbefore provided shall not be a general obligation of the governmental agencies or municipalities, but shall be paid only out of revenues received from the service charges as provided in the preceding section, or from a sale of the property and franchises under a foreclosure of the mortgage. If a service rate is charged, to be paid as herein provided, such portion thereof as may be deemed sufficient shall be set aside as a sinking fund for the payment of the interest on said bonds, and the principal thereof at maturity.

Section 5. Governmental agencies or municipalities as herein mentioned instead of owning and operating a sewer system and sewage disposal plant, garbage collection and disposal system, as herein provided, may grant a franchise for a period not to exceed thirty years to any private corporation organized under, or authorized by the laws of this State to engage in such business, to build, construct, own and operate a sewage or garbage disposal system for the purpose of receiving and treating sewage and night soil and garbage as hereinbefore mentioned from such governmental agencies or municipalities. Such franchise may authorize the corporation to charge each person, firm or corporation owning property from which such sewage or garbage is received such a fee therefor as may be determined to be reasonable by the Public Utilities Commission of this State, upon proper application made either by such corporation, governmental agencies or municipalities and after a hearing thereon. Such franchise may also grant to the corporation the right and privilege to lay all such necessary intercepting and other sewers and connecting pipes in the streets and public alleys of the governmental agencies or of the municipalties as may be necessary to receive and conduct the sewage to the disposal plant and under such reasonable rules, regulations and supervision as may be established by the governmental agencies or the municipalities. Any such franchise shall be void unless approved by three-fifths of the electors of such governmental agencies or municipalities voting thereon at any general or special election.

Section 6. Any such governmental agencies or municipalities may enter into a contract with any corporation organized under or authorized by the laws of this State to engage in the business herein mentioned, to receive and treat in the manner hereinbefore mentioned the sewage, night soil and garbage thereof. Such contract may authorize the corporation to charge the owners of the premises served such service rate therefor as the Public Utilities Commission of this State may determine to be just and reasonable, or the governmental agencies or municipalities may contract to pay the said corporation a flat rate for such service, and pay therefor out of their general fund or assess the owners of the property served a reasonable charge therefor to be collected as hereinbefore provided and paid into a fund to be used to defray such contract charges.

Section 7. Whenever a court of competent jurisdiction in this State shall have ordered the installation of a sewage or garbage disposal system in any of the governmental agencies or municipalities herein mentioned, and the plans therefor shall have been prepared, and approved by the State Commissioner of Health, the legislative body or the respective legislative bodies thereof shall have authority to issue and sell the necessary bonds for the construction and installation thereof, including the disposal plant, and such intercepting and other sewers as may be necessary to permit the effective operation of such system; such bonds to draw interest at not to exceed six per cent per annum, and payable in not to exceed thirty years from the date of issuance; the legislative body or the respective legislative bodies to determine the denomination of said bonds and the date, time and manner of payment. The amount of such bonds either issued or outstanding shall not be included in the amount of bonds which the said governmental agencies or municipalities may be authorized to issue under any statutes of this State or charters. Governmental agencies or municipalities issuing bonds hereunder in excess of the limit of the authorized bonded indebtedness fixed by statutes or charters, the principal and interest of which are not to be paid out of funds created from service charge, as hereinbefore provided, may raise such a sum annually by taxation as the legislative body or respective legislative bodies may deem necessary to pay interest on such bonds, and to create a sinking fund to pay the principal thereof as it falls due. Such annual amount may be in excess of the authorized annual tax rate fixed by the statutes or charters. Except as otherwise provided in this act, all bonds issued hereunder shall be issued and sold in conformity to the provisions of act number two hundred seventy-three of the Public Acts of nineteen hundred twenty-five or as it may hereafter be amended.

Section 8. Whenever an order shall have been made by any court of competent jurisdiction, as hereinbefore provided, the fact that such order was issued shall be recited in the official minutes of the legislative body or the respective legislative bodies. The said body or bodies shall thereupon require that plans and specifications be prepared of such sewage or garbage disposal system, including the necessary storm and sanitary sewers, which plans when submitted and approved by the legislative body or respective legislative bodies shall be submitted thereafter to the State Commissioner of Health for his approval. If such plans are so approved, the legislative body or respective legislative bodies shall thereupon authorize the issuance and sale of the necessary bonds to establish the proposed system.

Section 9. The authority hereby given shall be in addition to and not in derogation of any power existing in any of the counties, cities or villages under any statutory or charter provisions which they may now have or may hereafter adopt.

Section 10. Proceedings under this act shall be taken only in a court of competent jurisdiction in the county in which the proposed interceptors sewage or garbage disposal plants are to be constructed.

Section 12. Whenever it is deemed expedient for the safety and health of the people, governmental agencies and municipalities are hereby authorized to enter into agreement with each other to raise money, issue bonds to erect and maintain intercepting sewers and sewage treatment plants.

Section 13. Whenever governmental agencies and municipalities shall desire to act under the provisions of this law, the relationship established between such governmental agencies and municipalities shall be fixed by contract, and such contracts may be made by governmental agencies and municipalities under the provisions of this act in a manner and to the extent that natural persons might make contracts for like purposes. Such contracts before becoming operative shall be approved by a vote of the majority of the members elect of each of the respective legislative bodies of the governmental agencies and municipalities operating under the provisions of this act.

Secton 14. If any clause, sentence, paragraph, section or part of this act shall for any reason be adjudged or decreed to be invalid by any court of competent jurisdiction, such judgment or decree shall not affect, impair or invalidate the remainder of this act, but shall be confined in its operation to the clause, sentence, paragraph, section or part hereof directly involved in the controversy in which said judgment or decree shall have been rendered.

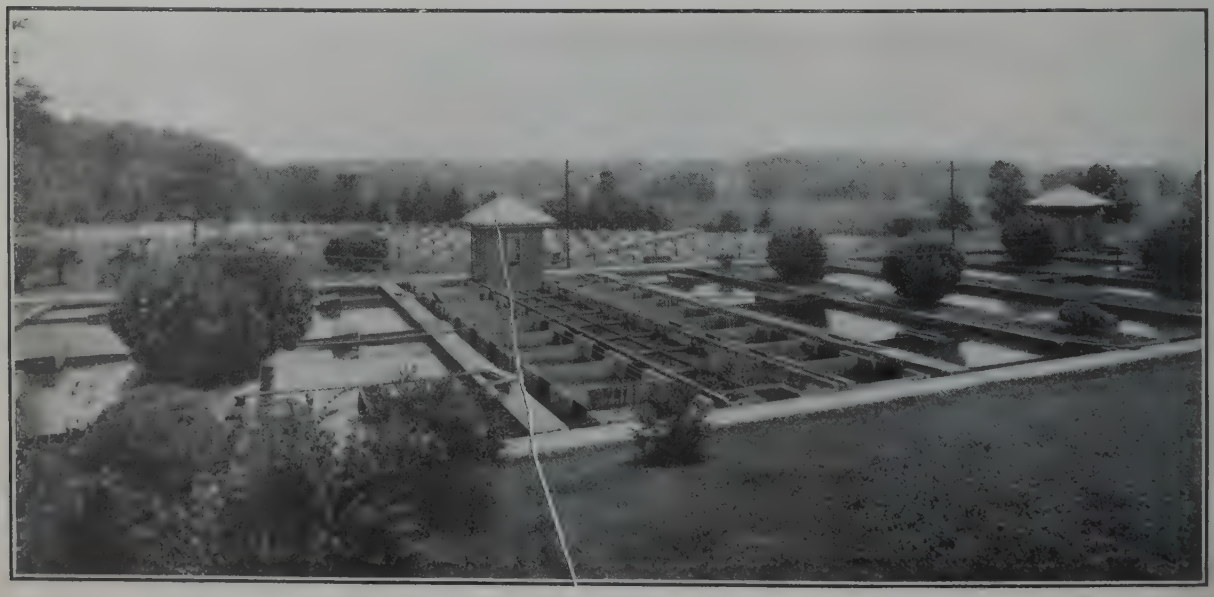
This act is ordered to take immediate effect.

OHIO SEWER RENTAL LAW

(Section numbers, Ohio General Code. Effective July 30, 1923.)

Sec. 3891—1. The council of any city or village which has installed or is installing sewerage, a system of sewerage, sewage pumping works or sewage treatment or disposal works for public use, may by ordinance establish just and equitable rates or charges of rents to be paid to such city or village for the use of such sewerage, a system of sewerage, sewage pumping works or sewage treatment or disposal works by every person, firm or corporation whose premises are served by a connection to such sewerage, system of sewerage, sewage pumping works or sewage treatment or disposal works. Such charges shall constitute a lien upon the property served by such connection and if not paid when due shall be collected in the same manner as other city and village taxes. The council may change such rates or charges from time to time as may be deemed advisable. Provided, however, that in a municipality operating under a municipal charter the council or other legislative body may establish the schedule of rates herein authorized and provide for its administration by designating the department or officer of the municipality to be charged with the enforcement of the provisions of this act. (110 v. 370.)

Sec. 3891—2. In a city the director of public service shall manage, conduct and control the sewerage system and sewage pumping, treatment and disposal works and when the council has established a schedule of rates or charges of rents for their use shall collect sewer rentals, and he shall appoint the necessary officers and agents for such purposes. (110 v. 370.)



Sewage Disposal Plant, Peach Creek, Atlanta, Ga.

Sec. 3891—3. When the council of a village has established a schedule of rates or charges of rents for the use of the sewerage system and sewage pumping, treatment and disposal works, the board of trustees of public affairs shall manage, conduct and control such sewerage system and sewage pumping, treatment and disposal works and shall collect sewer rentals and shall appoint necessary officers and agents for such purposes; and shall assume all duties, in relation to sewers, imposed upon the street commissioner by Section 4364 of the General Code, whereupon the street commissioner shall be relieved of such duties. (110 v. 370.)

Sec. 3891—4. The director of public service and the board of trustees of public affairs may make such by-laws and regulations as may be deemed necessary for the safe, economical and efficient management and protection of the sewerage system and sewage pumping treatment and disposal works; and for the construction and use of house sewers and connections to the sewerage system. Such by-laws and regulations shall have the same force and effect as ordinances when not repugnant thereto or to the constitution or laws of the state. (110 v. 370.)

Sec. 3891—5. The funds received from the collection of sewer rentals shall be deposited weekly with the treasurer of the corporation. Money so deposited shall be kept as a separate and distinct fund and shall be known as the sewer fund. When appropriated by council, it shall be subject to the order of the director of public service of a city or board of trustees of public affairs of a village. Such director or board shall sign all orders drawn on the treasurer of the corporation against such fund. This fund shall be used for the payment of the cost of the management, maintenance, operation and repair of the sewerage system and sewage pumping, treatment and disposal works and any surplus in such fund may be used for the enlargement or replacement of the same and for the payment of the interest on any debt incurred for the construction of such sewerage system and sewage pumping, treatment and disposal works, and for the creation of a sinking fund for the payment of such debt, but shall not be used for the extension of a sewerage system to serve unsewered areas or for any other purpose whatsoever. (110 v. 370.)

Acknowledgment.—The foregoing is a paper presented Oct. 23 at the 5th annual Missouri Water and Sewerage Conference.

Water Filtration Plants in Pennsylvania

Some interesting information on the purification of water in the state of Pennsylvania was given by H. E. Moses, Assistant Chief Engineer, Pennsylvania Department of Health, in a paper presented at the 33rd annual meeting of the Pennsylvania Water Works Association. The notes following are taken from his paper.

The first public water works in the United States were those of Boston, and built in 1652. Eighty-four years later the first Pennsylvania water works was installed at Schaeffertown in 1736. In this state, at Bethlehem, in 1754, there was put into operation the first water works pumping plant in the United States. One hundred and fifty-three years after the installation of the Schaeffertown works, Pennsylvania saw its first filter plant.

Records of the early water filtration plants are meagre, but it appears that in 1889 one was built at New Bethlehem, Clarion County. This was a single unit of the rapid sand type with a daily capacity of 150,000 gal. Three years later the next plant was built at Beaver Falls, Beaver County, replaced by a new plant in 1924, while the Gettysburg plant was installed in 1893.

Table I—Summary of Filtration Plants in Pennsylvania as of June 1, 1928

Type plant	No. plants	No. units	Million gals. daily Rated capacity	Water filtered	Population in district	No. of Consumers
Rapid	164	685	487.50	270.67	2,139,731	1,856,910
Slow	10	38	41.60	34.30	223,829	220,365
Slow and rapid	5	106	119.50	90.80	627,898	585,000
Preliminary and slow	4	91	258.50	238.50	1,543,500	1,393,400
Pretreated and slow	1	56	200.00	121.00	690,000	640,000
Coke and rapid	1	1	0.20	0.20	62,327	1,800
Pressure	9	27	12.13	6.44	88,950	69,950
Total	194	1,004	1,119.43	761.91	5,376,135	4,767,425

The growth by years is shown in the following table:

Record of Filtration Plants Installed According to Year First Built to June 1, 1928

Year	Plants No.	Year	Plants No.	Year	Plants No.
1889	2	1903	5	1917	8
1890	..	1904	6	1918	4
1891	..	1905	7	1919	4
1892	1	1906	8	1920	7
1893	..	1907	2	1921	9
1894	1	1908	8	1922	2
1895	3	1909	5	1923	8
1896	3	1910	11	1924	6
1897	2	1911	7	1925	9
1898	2	1912	7	1926	5
1899	..	1913	7	1927	7
1900	2	1914	16	1928	6
1901	2	1915	6		
1902	6	1916	5	Total	194

The growth by periods is well shown in the table below. It will be noted that the greatest number of plants were built from 1910 to 1919, but in terms of rated capacity the previous decade totaled three times the amount with only slightly more than one-half as many plants. However, this period includes the Pittsburgh and all of the Philadelphia plants, except Queen Lane. It means that 1910-1919 witnessed the extension of filtered water to many of the smaller communities outside the largest centers of population. This, likewise, was true, although to a lesser degree, from 1920 to 1928.

Installation of Plants by Periods

Type of plant	Period—Years exclusive 1889 1899	1900 1909	1910 1919	1920 1928 (June 1st)
Rapid	11	33	60	58
Slow	1	4	8	....
Slow and rapid	....	2	....	....
Preliminary and slow	....	4	1	....
Pretreated and slow	....	1	....	....
Coke and rapid	....	....	1	....
Pressure	2	2	5	1
Total plants	14	46	75	59
Rated capacity million gallons daily	38.35	559.11	199.32	104.21

NOTE: In above table plants are listed according to first year in which plant is built—new plants only.

As a contrast to the slow growth at the beginning, only 14 plants in the first 10 years, 16 plants were built in the last two years having an aggregate rated capacity of 60 m.g.d.

A summary of filtration plants as of June 1, 1928, is shown in Table I.

On June 1, 1928, there were in Pennsylvania 194 filtration plants, almost all of which are in daily operation, serving four and three-quarter million people and producing in round figures 760,000,000 gal. of water every 24 hours. These plants combined have a rated capacity of slightly more than 1,100 mil. gal. daily. In addition to being filtered the water is, with very few exceptions, also chlorinated.

Cost of Ice Water Drinking Fountains.—The Water Board of Cambridge, Mass., maintains nine ice water drinking fountains during the summer months. The average cost per day per fountain of furnishing the ice was $1.75 in 1928; $1.63 in 1927 and $1.75 in 1926.

Accounting for the Water Pumped at Dubuque, Ia.

The percentage of salable water and pumpage accounted for by the Water Works of Dubuque were as follows for the year ending March 31, 1929:

	Gal.	Per Cent
Salable	620,689,500	63½
No revenue	357,398,500	36½
Accounted for	713,516,500	73
Unaccounted for	264,572,500	27

The following table from the 29th report of the Water Department, of which John W. McEvoy is Superintendent, shows the uses of the water pumped during the year:

	Gal.
Salable water	620,689,500
General flush of distribution system	6,500,000
Flushing 1,218 hydrants at 7,500 gal. each	9,135,000
Extension and plumbers' ditches	2,000,000
Service leaks, 96 to 100,000 gal. each	9,600,000
Eight hydrants broken (30 min. at 1,000 gal. per min.)	240,000
Cleaning level reservoir (3 times)	1,500,000
Draining West Third St. Reservoir	4,000,000
Known leakage in West Third St. storage reservoir (24,000 gal. per day)	8,760,000
Meters tested at 35 gal. each	200,000
Eagle Point Station	2,000,000
By Pass from Low Pressure to Level Reservoir	2,592,000
Flushing city streets and sewers	20,000,000
Two horse fountains and 8 bubblers	8,800,000
Fire department	8,500,000
City parks (120 days at 10 hours)	3,000,000
Bathing beach and athletic field	1,500,000
Ice rinks (seven)	4,500,000
Free water furnished the city	46,300,000
Total accounted for	713,516,500

Pumpage accounted for divided by the actual pumpage equals the per cent of pumpage accounted for; 713,516,500 divided by 978,088,000 equals 73 per cent.

Control of Filter Washing

Studies Show That 2.7 Ft. Vertical Rise Most Economical

By EDWARD S. HOPKINS
Principal Sanitary Chemist, Bureau of Water Supply, Baltimore, Md.

DUE to the serious clogging of sand filter beds in different parts of the country there is an opinion among many plant operators that the accepted standard wash of 2 ft. vertical rise per minute is not sufficient to keep the beds in proper condition.

This study was undertaken for the purpose of learning, if possible, some relation between washing characteristics and maintenance of clean beds with subsequent long periods of operating service. It being assumed that clean beds would minimize the possibility of mud ball clogging.

Clarity as Criterion of Cleanliness.—When washing filters it is the usual practice to utilize the clarity of the final wash water as the criterion of the cleanliness of the bed. This clarity being determined solely by visual inspection of the operator as the water passes into the drain troughs. Testing 7 experienced filter operators it was found that the turbidity of such wash water varied from 25 to 150 p.p.m., depending upon individual psychology and light conditions. Since it is logical to expect the period of filter operating service (filter runs) to be more or less controlled by the cleanliness of the bed, therefore the cleaner the bed, the longer the "filter runs" with other conditions being equal, due to a minimum initial mud load. This assumption is confirmed by a study of the curves in Fig. 2. Using a constant filtration rate (125,000,000 gal. per acre per day) with the applied water properly coagulated, having a turbidity between 4 and 7 p.p.m., it is shown that a minimum final wash water turbidity gives a maximum period of operation.

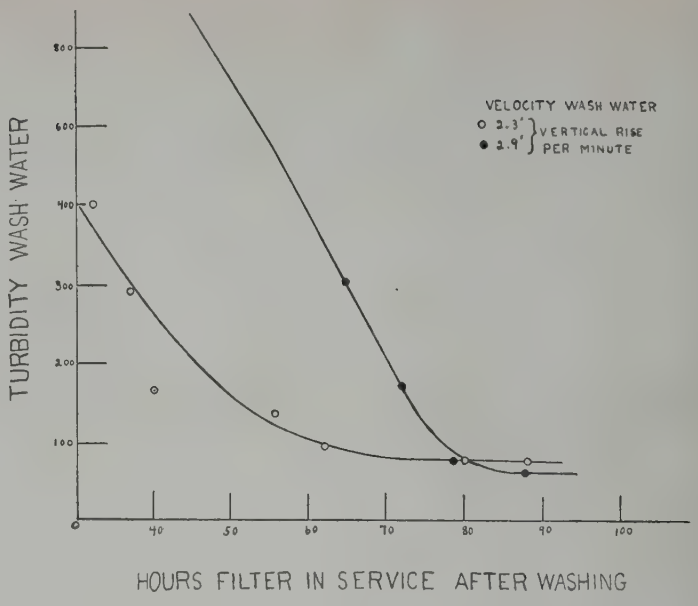


Fig. 2

Velocity a Factor.—These curves also indicate that the velocity of wash water is a factor in obtaining clean beds. When washing with a velocity of 2.9 ft. vertical rise per minute it will be noted that with a 1 minute wash and final wash water turbidity of 800 p.p.m. it was possible to obtain a filter run of 50 hours. Using a velocity of 2.3 ft. vertical rise, giving a turbidity of 400 p.p.m. for a similar period, a run of only 35 hours was obtained.

Further inspection of these curves show that the "filter runs" are practically constant for a final wash water turbidity of 75 p.p.m., thereby indicating that the bed is clean, with this condition existing for all velocities of wash water applied. Any increase in filter operating time greater than indicated, is due to the characteristics of the applied water rather than to washing conditions. These results confirm the belief that filters should be washed with the highest velocity comparable to plant design.

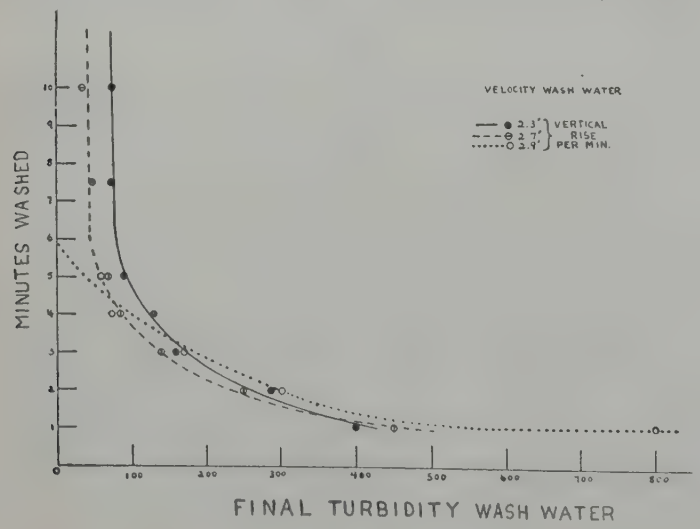

Fig. 1

Simple Control Method.—Since it is not practicable as routine procedure to make turbidity determinations of the wash water during the restricted washing period a simplier control method must be utilized. Such a control can be easily maintained by regulating the time of wash in relation to the velocity of wash water applied as shown in Fig. 1. Inspection of these curves will show that the maximum cleanliness of bed (75 p.p.m. final wash water turbidity) does not require prolonged washing. Filters washed in accordance with these curves would be in this ratio:

2.3 ft. vertical raise per minute, requires a 6-minute wash,
2.7 ft. vertical raise per minute, requires a 4-minute wash,
2.9 ft. vertical raise per minute, requires a 4-minute wash.

A 4-minute wash at 2.7 ft. vertical rise is, therefore, the most economical rate, thereby giving an easily controlled cleanliness of bed, with assurance that the maximum "filter runs" are being obtained. These results would indicate that the present accepted standard of 2 ft. vertical rise is inefficient and if plant design will permit the use of these higher velocities, without loss of sand, increased "filter runs" will be obtained.

Acknowledgment.—The above is a paper presented at the 1929 Conference of the Maryland Water and Sewerage Association.

Methods and Costs of Day Labor Construction of Water Mains and Sewers

Organization, Equipment and Methods Used by a Sanitary District in Maryland, and a Comparison of Cost of Machine and Hand Work in Trenching

By H. ROLAND DEVILBISS

Department Engineer, Washington Suburban Sanitary District, Hyattsville, Md.

THE Washington Suburban Sanitary District lies partly in Prince George's and partly in Montgomery County, Maryland, adjacent to the District of Columbia, and has an area of about 94 square miles. In addition, Gaithersburg and Washington Grove, lying in the central section of Montgomery County and embracing an area of about one square mile, form a detached part of the Sanitary District.

Organization.—The office of the chief engineer, who has charge of all engineering activities, is divided into two main departments, construction and maintenance and operation, and four divisions, design and drafting, surveys, plumbing, and accounts. Each is under a department or division engineer, responsible to the chief and deputy chief engineers.

The construction department engineer has direct charge of the construction of all water and sewer lines, filtration plants, water and sewage pumping stations, sewage disposal plants, water and sewer connections, purchase of construction equipment, small tools and supplies, and the inspection and handling of all construction material. Working directly under the department engineer are two resident engineers, one in charge of the eastern district and the other the western district, who supervise the work of the day labor forces on main lines and house services, and also of contract work. Assisting each of these men is a line and grade party, consisting of an instrumentman and rodman, which sets lines and grades and takes final measurements of completed work. On contract work inspectors are furnished these districts, whose duties are to see that the work is carried along in strict accordance with the specifications. An assistant engineer in the office has charge of house connection records, sketches, and the issuance of permits; and in addition looks after the office work of the plumbing division. At the warehouse is a storekeeper and an assistant whose duties are to inspect and check the receipt of all materials and their delivery to the various projects to be constructed. Working under these men are mechanics, machine operators, blacksmiths, carpenters, truck drivers and a street repair gang. Machine operators on assignment to a district work directly under the resident engineer. A final inspector and his gang report to and work directly from the department engineer's office.

The size of the day labor forces varies in accordance with the volume of work to be completed during the year. The maximum number of day labor gangs on water and sewer lines has been 11 and the minimum 2, while the maximum number of laborers employed on this class of work has been 396 and the minimum 21. On water and sewer house connections the maximum number of gangs has been 5 and the minimum 1, while the maximum number of laborers has been 79 and the minimum 13.

Work Accomplished.—During the past ten years this organization has constructed or supervised the construction of 190 miles of water lines, ranging in size from 1¼ in. to 24-in., 113 miles of sewer lines, ranging in size from 6-in. to 30-in., two water filtration plants and pumping stations, one having a capacity of 3,500,000 gal. per day, the other a capacity of 1,000,000 gal. per day, several large standpipes and elevated tanks, a sewage disposal plant having a capacity of 250,000 gal. per day, and four small sewage pumping stations, two each with a pumping capacity of 70 gal. per minute, another with a pumping capacity of 350 gal. per minute, and another with a pumping capacity of 300 gal. per minute, at an approximate total cost of $5,000,000. In addition 9,114 water services, ranging in size from ¾ in. to 8 in., and 6,368 sewer services were built.

The above figures do not include existing water lines, sewers, and water and sewer connections, purchased and incorporated into the district's systems at the beginning of operations, which amounted to approximately 53 miles of water mains, 56 miles of sewers, 1,586 water services, and 1,650 sewer house connections; nor do they include the expenses incurred in the purchase of these systems, or in the replacement of many old lines, the lowering of main services, and other incidental capital costs.

Equipment.—The hauling equipment consists of five 3½-ton trucks, three 1-ton trucks, three 1-ton dump trucks, and one 1-ton truck with dump body. In addition, four 1-ton trucks are equipped for use by the water and sewer house connection gangs.

Our excavating equipment consists of four trenching machines, two having a digging depth of 12 ft. and a maximum width of 33 in., one having a digging depth of 10 ft. and a maximum width of 30 in. and the other a digging depth of 7 ft. at 24-in. width and a digging depth of 5 ft. at 42-in. width.

Where one class of pipe line work is to be constructed and depths do not vary widely, the purchase of excavating equipment becomes a simple problem. In this district the problem is quite different. The territory is extensive and in most cases the lines authorized for construction by the commission involve both water mains and sewers in a single project. The average length of these installations is probably not greater than 800 ft.

For backfilling purposes we have four machines on full caterpillars, and equipped with boom attachments. In addition to refilling, these machines are used in lifting large boulders and rocks from trenches, unloading pipe from cars, lowering pipe into trenches, and withdrawing shoring from trenches.

We have three compressors, one having a capacity of 165 cu. ft. per minute, another a capacity of 90 cu. ft. per minute, both mounted on steel wheels, and another having a capacity of 90 cu. ft. per minute, mounted on a truck. The two mounted on steel wheels are moved from job to job on our trucks and are used where heavy rock cuts are encountered, while the one mounted on the truck is generally used in breaking concrete and macadam, and on trench work where a light rock cut is found. With the latter machine, speed of transportation is the big item and this compressor has proven valuable in breaking concrete and macadam for service connections. We are well equipped with concrete breakers, jackhammers, tampers and spades.

We have one 1½-ton crane mounted on a 7-ton truck and equipped with a ½ cu. yd. clamshell bucket. This machine is used in unloading cast-iron pipe and fittings from freight cars, loading trucks in our store-yard, unloading and handling crushed stone, gravel, cinders, coal, and in lowering large cast-iron pipe into trenches.

The crane was used successfully in excavating approximately 2,000 ft. of trench, averaging 8 ft. in depth, for a 30-in. reinforced concrete sewer. This work was in close proximity to a stream

and in marshy land. The machine was moved in while the ground was frozen, placed on a plank platform on the center line of trench, and carried on this platform throughout the work, which terminated at a paved roadway.

The tractor equipment consists of four small tractors. These are used mostly in moving construction materials and equipment to jobs which are not accessible to truck deliveries. Practically all of our trunk sewer work and some of the cross-country water lines fall into this class. In emergencies the maintenance and operating department has used the tractors in driving low-lift centrifugal and deep well pumps.

For trench pumps we have, mounted on steel wheels, eight 2-hp. gasoline-driven diaphragm pumps with 4-in. suctions, having a rated capacity of from 8,000 to 10,000 gal. per hour. We have also a number of 3-in. diaphragm hand pumps.

Type of Pipe for Water Mains.—The distribution system has been constructed of a number of different types of cast-iron pipe, among which are sand-cast, deLavaud centrifugal, sand spun centrifugal, and McWane horizontally cast, without precaulked joints. The sand-cast pipe, in sizes up to 24 in., and the deLavaud centrifugal, in sizes up to 20 in., have been in 12-ft. lengths, with the exception that during 1920 a small percentage of the sand-cast was in 5-meter lengths. The sand spun centrifugal pipe, in sizes up to 12 in., has been in 16-ft. and the McWane pipe, which we have used only in the 6-in. size, has been in 16.5-ft. lengths. Nearly all of this material is purchased under competitive bidding.

No provision is made in our contracts for a differential on 16-ft. or 16.5-ft. lengths over 12-ft. lengths. During the past year, at the direction of the chief engineer, I prepared an estimate of the average saving per linear foot in laying 16.5-ft. lengths instead of 12-ft. lengths, on sizes ranging from 6-in. to 12-in., and the results are shown in Table I.

We have recently tried some 12-in. deLavaud pipe in 18-ft. lengths. It is too early to form a definite opinion of its advantages over 12-ft. lengths, but it is not suitable for curved pipe lines and there is difficulty in handling where trenches have to be braced.

Joints.—For jointing cast-iron mains, braided hemp packing and leadite are used. On lines crossing bridges a sleeve is placed near the center of the crossing and this joint, as well as joints on lines passing under streams, is poured with lead. In the former case the lead joints make additional provision for expansion and contraction in the line, and in the latter it has been found that lead in these locations is easier to repair, if necessary, than leadite. Some of the bridges on which we have water mains are subject to considerable vibration from heavy traffic. The leadite joints on bridges, however, have shown little leakage.

Fire Hydrants Have Sliding Frost Casing.—The type of fire hydrant used was designed by Mr. Robert B. Morse, Chief Engineer of the district. It has an attractive appearance and the internal parts are adapted from the standard Mathews hydrant manufactured by R. D. Wood & Co. One of the unusual features embodied in the design of the hydrant is a sliding frost casing, which for our purposes has a maximum range of 2 ft., although if desired the casing could be manufactured to give either a greater or smaller range of adjustment. In this district, where water lines are constructed in a majority of instances in advance of permanent grading, the adjustable frost case has proven to be of untold value. Hydrants manufactured for the district with the sliding frost casing are for 4½, 5, 5½ and 6½-ft. depths of trench. If the ground surface at the time of placing the hydrant required a 4½-ft. hydrant, the casing would be in a fully collapsed position with its top just above the ground, while if at a later date a fill was made and a 6½-ft. hydrant was required the barrel of the 4½-ft. hydrant would be removed, a 6½-ft. barrel inserted, and the frost casing extended to its full extent so as to allow its top to protrude slightly above the finished grade. The operation would be reversed if a 6½-ft. hydrant was originally required and the street was graded off sufficiently to make a 4½-ft. hydrant suitable. Intermediate lengths of hydrant, of course, are used as required by conditions. Only a slight amount of digging is necessary in adjusting sliding frost casings to new grades, materially reducing the expense involved in changing other types of hydrants.

In placing fire hydrants a pocket 18 in. deep and 24 in. wide is excavated directly beneath the location of the hydrant, and this space is filled with stone, gravel or brick bats. This bedding affords a solid foundation for the hydrant and also allows proper drainage. After the hydrant has been placed and well braced back of the elbow, it is surrounded with the same class of previous material to a point well above the drip.

All hydrants have a main valve opening of 5¼ in. Hydrant leads are 6 in. in diameter and leads off from mains larger than 6 in. have a valve placed on them three feet from the face of the hydrant.

Laying Water Mains.—Water mains are laid with nearly the same precision, as to grade, as are our sewer lines. The construction department is furnished with a profile of the street, together with the elevations of the invert of the line at the various stations. Grade lines are set on the surface by the line and grade party and the foreman is furnished with a cut sheet which is followed in the laying of the main. Each pipe is graded with a rod in the same manner as sewers are graded, while the alignment of the main is generally done by eye, but with great care, nevertheless.

During the first few years the depth at which mains were to be laid was determined by the engineer in the field. Most of the streets and roadways in which mains were built were not at finished grade, and sufficient information was not available in the field to form a basis for reliable judgment as to the probable future condition. The result was that in some cases we have had to return and lower the mains, while in others we have mains deeper than necessary, due to heavy fills subsequently made. At a later date, the construction plans showed a reasonable finished street grade, as well as existing ground surface and the desired invert line for the main. The cuts from the existing ground surface to invert were scaled from the drawings in the field and the foremen attempted to dig to the required depths. Although this method was better than the crude one originally adopted, and generally used elsewhere, it was far from satisfactory and was in turn superseded by the plan first described.

Lowering Mains.—During the past ten years we have lowered 2,200 ft. of 4-in., 2,500 ft. of 6-in., 6,500 ft. of 8-in., 56 ft. of 10-in., 50 ft. of 12-in. and 550 ft. of 16-in. water main, most of which lengths, however, were in the systems purchased.

No difficulty has been experienced in lowering mains with either lead or leadite joints. A great many lead joints after lowering require recaulking, while with care very little repair has been necessary with leadite joints. Once in a great while a leadite joint will leak slightly, in which case the material is cut out at this point and the void is caulked with lead wool.

Sewer Construction.—Our specifications for vitrified sewer pipe require that all pipe shall be what is commercially known as "first quality" pipe, shall be in 3-ft. lengths, deep and wide socket, and double strength on sizes from 15 in. up. They further require that the contractor furnishing the material must submit to the chief engineer the name or names of the firm or firms which are to supply the pipe, together with the manufacture or manufacturers and location of the factory. The right is also reserved to require

Table I

Size, In.	Leadite and Jute per ft., 12-ft. lengths	Leadite and Jute per ft., 16.5-ft. lengths	Saving on Materials, 16.5-ft. lengths	Estimated Saving on Labor, 16.5-ft. lengths	Total Saving in using 16.5-ft. lengths
6	$0.032	$0.028	$0.009	$0.005	$0.014
8	0.0451	0.0329	0.0122	0.008	0.0202
10	0.0563	0.0409	0.0154	0.009	0.0244
12	0.0717	0.0522	0.0195	0.010	0.0295

the contractor to furnish an affidavit from the manufacturer that all pipe furnished is No. 1 pipe and first class in every respect.

Laying Pipe.—One of the most important things in the construction of a sewer system is the proper alignment and grading of each line constructed. In our district each length of pipe as it is laid is tested for line with a plumb bob and with a grade pole for exact elevation. After completion of an extension the lines are gone over by an inspector whose duties are to clean the lines of any sand or mud deposits that may have gathered during construction, to see if the alignment and grades between manholes are correct, and to search for leakage and other defects that may be visible in the manholes and pipe lines.

Final inspection is made of both contract and day labor work and in very few cases has it been necessary to reopen a trench to correct for alignment and grade. Occasionally a crushed pipe is found and repaired.

Y-Branches.—At first we placed Y-branches on our lines for vacant lots as well as for the existing houses. Vacant lots, however, are often not developed as originally planned and we were not a great while in learning that efforts towards making intelligent provision for Y-branches to serve vacant lots were mostly wasted. Further, the expense of placing Y-branches was considerable and much of it was lost for all time.

We now place Y-branches to provide only for existing houses and cut in on the lines for additional connections, in the manner to be described later.

Joints.—The materials which we have used in jointing sewers are cement, Hydrolene-B, Jointite and G-K.

Cement was first used and probably successfully in dry trenches and at points where no fear from root penetration need be entertained. In wet trenches, however, where underdrains are not used and where difficulties are always encountered in keeping water down, it is practically impossible for a foreman to obtain consistently good cement joints. Again, for the engineer to be assured of a proper cement joint, as generally specified, backfill certainly should not be permitted until the cement has had the opportunity of taking a fairly good set. It is generally believed, or at least stated, that backfilling over cement joints may be carried on, with care, directly after pipe laying. Care in doing this consists of refilling over the center of the pipes between joints, the backfill finally reaching a point from which it gradually rolls down and covers the joint. Refilling then proceeds in the ordinary manner. All joints may not be disturbed by this method but if some of the recently made joints are opened up after being covered by several feet of backfill you will find in a great many cases that the cement which was applied outside of the annular space has been wasted. I firmly believe that cement can be used successfully only in dry trenches, where backfilling need not proceed until the cement has become hard, and at points where there is no danger from root penetration.

Tests for Joints in Wet Trenches.—Inasmuch as a large proportion of our sewers are laid in wet trenches, and owing to some differences of opinion as to the pouring of joints which were moist and in some cases partly submerged, a few tests were conducted to determine the character of joints that could be secured under these conditions. In making these tests 6-in. deep and wide socket pipe was used, having a well-defined scoring on the spigot and the inside of the bell. The joints were packed with untarred jute and a depth of 1½ in. was allowed for the bituminous material. Water in which the tests were conducted was about the same turbidity encountered in the average wet sewer trench.

First: A number of sections of two lengths each were placed horizontally, the joints were packed and the inside of the bell and the outside of the spigot were moistened by running a wet brush around them. The joint was poured without any difficulty whatever. After pouring the joint one end of the pipe was sealed and the joint was submerged under 2 ft. of water for a period of 18 hours. Infiltration was negligible, not amounting to more than a tablespoonful in this period. The bells were broken and left the material easily, and the joint was cut and pulled from the spigot just as easily. Slight adherence existed between the two surfaces but the material was well keyed into the scoring and this undoubtedly was preventing infiltration. The joint itself showed no imperfection.

Second: A number of joints were poured by different methods with the invert of the pipe submerged 2 in. These methods were:

A. The joints were packed and the pouring gate was made directly on top of the pipe. The material was then poured and allowed to run down on both sides of the pipe. In some cases we had a joint that showed a solid face, while in most of our attempts the material failed to run on the bottom of the joint. In those that showed a solid face we found that at the bottom only a thin crust existed on the face of the joint, the material failing to fill the bell at this point. There was no adherence between surfaces.

B. The pouring gate in this case was placed slightly to one side of the top of pipe and the poured material forced the water around ahead of it. This method showed some improvement and some very good joints were obtained. All joints showed perfect on the face, but we found, on examination, a few with imperfections which would have allowed considerable infiltration.

C. In this case a small opening was left between the runner and the face of the bell at the bottom of the joint. The gate was built on top of the pipe and the bituminous material running down on each side of the pipe forced the water out at the bottom. This opening was stopped quickly with a piece of clay as soon as the compound appeared and the pouring of the joint was then completed. A number of joints were poured in this way and in no case did we fail to get a good result. The adherence in this case was about the same as obtained with the surfaces moist.

Water and Sewer House Connections.—Water and sewer house connections are built by the district as far as the property line. Table II gives the charges for the several sizes of connections which have obtained since the work started. It will be noted that these charges are gradually increasing which can be largely ascribed to the fact that increased width of streets in new subdivisions and a greater number of paved streets have caused the cost of doing the work to become materially greater.

The costs include the tapping of the water main or sewer, the necessary piping and fitting to carry the service to the property line, and on water services the meter housing and the placing of the meter.

Water.—For water services we first used galvanized genuine wrought-iron pipe. This material was superseded several years later by 1¼-in. cast-iron pipe, and during the past two years we have used copper tubing for services ranging in size from ¾ in. to 1½ in. On services larger than these cast-iron pipe is still used.

While both water and sewer connections are desired to a property the water service is laid in the same trench with the sewer connection. This is accomplished by tamping the backfill over the sewer pipe to the point at which the service is to be placed and then wedging a few pieces of timber across the trench to support the tubing. If the applicant desires water service only and the main is on the opposite side of the street from the property to be served shafts are opened on both sides of the road and the connecting channel is made by means of a 2-in. earth auger made up in sections 2 ft. long. This method has been used successfully under roadways 20 ft. wide. The copper

Table II

	Water, Size						Sewer, Size	
Year	¾ in.	1 in.	1¼ in.	1½ in.	2 in.	Over 2 in.	6 in.	Over 6 in.
1919 to 1924	$25.00	$30.00	$35.00	$40.00	$50.00	At cost but	$25.00	At cost but
1924 to 1925	30.00	35.00	42.00	50.00	60.00	in no case	30.00	in no case
1925 to 1928	35.00	42.00	50.00	60.00	74.00	less than	35.00	less than
1928 to 1929	42.50	50.00	60.00	72.00	90.00	cost of 2 in.	42.50	cost of 6 in.

tubing is easily passed through the opening made by the auger.

Water mains are tapped at an angle of 45 deg. and the end of the copper tubing is bent into the shape of a goose neck and connected to the corporation cock by means of a copper to brass fitting. Where it is necessary to joint two pieces of tubing a copper to copper coupling is used. Meters are placed outside in a housing, either between the curb and sidewalk or just back of the sidewalk. At the meter housing the tubing is bent to an angle of 90 deg. and carried vertically up through the housing and connected to the inlet side of a meter yoke by means of a copper to iron fitting. From the outlet side of the meter yoke galvanized genuine wrought-iron pipe is used to the property line.

Water services are laid at a minimum depth of 4 ft. The meter housing for ⅝-in. and ¾-in. meters consists of 18-in. terra cotta pipe 2 ft. long on which is placed a hollow concrete truncated cone 18 in. by 15 in. by 18 in. high. The frame and cover rest on this cone, making the total depth of the housing 46 in.

The meter yoke is equipped with a cut-off valve on the inlet side, which eliminates the need of curb cocks and boxes. Yokes are so placed that the inlet and outlet of the meter are 18 in. below the surface.

Water services are divided into two classes, single and double. Single water connections are mostly ¾ in. in diameter and provide service for one house. A double connection provides service for two houses and is usually 1 in. in diameter to the under side of the meter yoke where it is divided by a 1-in. by ¾-in. by ¾-in. tee, the branches of which are connected to the inlets of the two meter yokes which are placed in one housing. From the outlet sides of the yokes ¾-in. pipes are extended to the individual property lines. This type of connection, as a rule, is located near the dividing line between the properties served.

Sewer Connections.—As previously stated Y-branches are placed only to serve existing houses. As vacant lots are developed provisions for tapping the sewers must be made. For this purpose on sewers from 8 in. to 15 in. in diameter we have been using what is commercially known as a Washington Standard Thimble-Y. The Thimble-Y is an extra heavy soil pipe fitting and is made in 5-in. and 6-in. sizes. To place the Thimble-Y it is necessary to cut an opening in the side of the sewer slightly larger than the diameter of the connection to be made. The Y has a thin spigot 1 in. in depth which is placed in above-mentioned opening and is prevented from protruding into the barrel of the sewer by a flange which fits neatly against the barrel of the pipe. A concrete collar is then placed around the Y and extends one foot on each side of the tap made in the sewer. Occasionally, a length of pipe is broken in cutting the opening but the percentage of breaks, as compared with the number of taps made, is small.

Following suggestions of the chief engineer our office has recently designed a much lighter and less costly, but just as serviceable, sewer thimble, which is now being manufactured and will be used hereafter.

On 6-in. sewers the line is broken and a regular terra cotta Y-branch is inserted.

All ordinary sewer house connections are 6 in. in diameter and, when possible, are so laid as to give a cover of at least 7 ft. at the property line, except where houses are on a terrace.

Sewer connections are divided into two classes, single and double, the single connection being constructed in the ordinary manner, while the double is laid as one connection to a point between the curb and property line, where it divides by means of a Y, one branch going straight to one property and the other branch going at an angle of 45 deg. to the adjoining property.

Costs.—Perhaps a discussion of recent costs will prove more interesting than will one of the costs of several years ago when wages and prices of materials were constantly changing. During the past two years these items have been fairly stable and therefore, in Tables III and IV are shown the volume of work done and costs for the years 1927 and 1928, respectively, on both water mains and sewer lines constructed by the district's day labor forces. In addition, these tables further show a comparison of costs of machine work versus hand work.

The costs shown in these tables include every expense incident upon the work—labor, materials, supplies, small tools, equipment, transportation, repaving, maintenance of trenches for a period of three months, engineering (including surveying and designing) and administration. On water mains the costs include foundry inspection, fittings, valves, valve boxes, fire hydrant leads and fire hydrants; and on sewer lines they include manholes, manhole steps and manhole frames and covers—in other words, the lines complete. The costs per lineal foot include, therefore, every item of expense incurred from the time the project is authorized for construction by the commission until it is completed and placed in operation.

In 1927, 90 water projects were constructed having an average length of approximately 591 ft., and 58 sewer projects having an average length of 382 ft.; while, in 1928, 119 water projects were constructed having an average length of approximately 755 ft., and 66 sewer projects having an average length of 837 ft. From this one can readily see the number of times our gangs are moved during the course

Table III—Comparison of Cost Machine Work Versus Hand Work—1927

of a year, and moving from one project to another involves considerable expense, not only in the actual cost of moving, but also in the loss of time. Where possible, the move is made after working hours and the latter loss eliminated, but in the majority of cases the move, unfortunately, has to be made during hours.

On water mains our standards require a minimum cover of 4 ft. In a great many sections of the district the streets have not been cut down to the final grade and the mains consequently have to be laid at an excessive depth, anticipating that some time in the future the street will be brought to a finished grade. While we do not classify our excavation depths on day labor work, the writer feels safe in saying that the average depth of water trenches on all sizes of water mains is at least 6 ft. Naturally, these ungraded streets increase the depths of the sewers and frequently to an amount greater than our machines will excavate, thereby making it necessary to handle this deeper excavation by hand.

In the northern and western sections of the district considerable rock is encountered, while in the southern and eastern sections we have to contend with caving ground, water, silt and quicksand.

Machine Work Versus Hand Work.—Some work on machine jobs necessarily has to be done by hand; for example, the crossing of gas mains and services, culverts, tunneling of improved roadways and operations in the proximity of trees, poles, etc. This kind of hand work is included in the tabulated machine costs, while in the hand work costs no machinery whatever was employed.

In Table IV it will be noted that machine work on 2-in. mains and smaller costs $0.28 more per foot than did hand work. Only parts of these jobs could be done by machine on account of rock. This, together with the small volume of work done, caused the cost to be exceedingly high. Again, in Table III, it will be noted that the cost of a short line of 20-in. water main was $8.45 per foot. This job was located in the eastern section of the district, in an ungraded street, which required the main to be laid at an average depth of 8 ft. At a depth of 3 ft. quicksand and water were encountered, necessitating the balance of the excavation to be done by hand, tight shoring driven, and pumps operated 24 hours per day. In addition to these troubles, a rainy period of several days occurred during the course of construction. These cases are mentioned merely to show conditions frequently met with in the district. Similar cases could be cited on other sizes of lines.

Acknowledgment.—The foregoing is an abstract of a paper presented at the 1929 Conference of the Maryland Water and Sewerage Association.

A New Lining for Cast Iron Pipe

The engineers of the Wailes Dove-Hermiston Corporation, working in cooperation with the engineers of the United States Pipe & Foundry Company, have recently developed an efficient method for lining cast iron pipe with their bitumastic material. Although the bitumastic lining is not a new development in the field of pipe construction, except in cases of extreme necessity the difficulty of application of this lining to the inner surface of large diameter pipe has hitherto been a handicap to its widespread use. The old method of applying it with a brush was tedious, expensive and slow. The new method recently developed is efficient, rapid and economical.

The applications of this lining to the trade are numerous indeed. Bitumastic Lining is stated to be completely resistant to both concentrated and dilute acids, as well as to alkalis and corrosive liquids of all types and degrees. For piping systems which carry waters strongly impregnated with sulphur, and whose reaction is therefore slightly acid, the use of bitumastic lining is claimed to be ideal. When the water is alkaline, the corrosive effect on the bitumastic lining is stated to be nil.

In addition to the resistance of this lining to the various liquids which may be passed through the pipe, the smooth glossy surface is stated to present no lodging place for tubercles, barnacles or other growths with which it may come in contact. The smooth glossy surface, which resembles baker enamel, is claimed to permit the liquids to flow through the pipe with considerably less frictional loss than is the case with uncoated pipe, thus producing a greater pipe line efficiency.

The new method of applying this lining makes use of a new application of an old theory—that of centrifugal force. The bitumastic enamel is heated in a cauldron to the proper melting temperature. The pipe to be coated has previously been dipped in a priming coat and has been allowed to completely dry. The pipe is placed on rollers, driven by an electric motor, and is caused to rotate rapidly. The correct amount of bitumastic enamel, being now quite fluid, is poured into a steam-heated trough which is run into the rotating pipe and tipped over evenly, distributing the bitumastic lining along the entire length of the pipe. In a moment the material is distributed by centrifugal force over the entire inner surface of the pipe, and rotation is continued until the material has completely hardened. If a double lining is required, the second layer is put in before the first is entirely solidified. Thus, a layer of Bitumastic Enamel may be applied of any desired thickness without difficulty.

On Sept. 24th, a number of hydraulic engineers, who are especially interested in the elimination of corrosion or tuberculation on the inside of cast iron pipe lines, were invited to the Burlington Plant of the United States Pipe & Foundry Company to witness a demonstration of the application of the lining by this process. Fifty prominent engineers from New York, Philadelphia, Baltimore and points more remote responded. Two pipe were lined, both 48 in. in diameter, and both pipe were handled with ease and dispatch by the perfectly trained crew. The first pipe contained a standard lining approximately $\frac{5}{32}$ in. thick, while the second was lined with double thickness. Great admiration was expressed by all present over the efficient manner in which the work was done as well as over the excellence of the effect produced.

Due to the character of the water carried in certain sections of the country, tuberculation in pipe lines has, over a period of years, reduced the carrying capacity of these lines. Engineers are of the opinion that the use of the bitumastic lining will eliminate this trouble. An example of the efficiency of the bitumastic lining will be found in the parallel 36-in. and 42-in. lines which form the Narrows Siphons carrying the water supply to Staten Island, New York. The older of these lines has been in service over 15 years, carrying soft water. The last examination showed the bitumastic lining to be in excellent condition, and the lines have retained their full carrying capacity.

Silting of Reservoirs

In a discussion in Vol. 93, 1929 Transactions of the American Society of Civil Engineers, R. L. Meeker, Consulting Engineer, Denver, Colo., gives the following table summarizing the losses in various reservoirs in the southwest from silt deposition:

Silt Deposition, Channel Reservoirs, Southwestern United States

Reservoir	Stream	State	Drainage area in square miles	Original capacity, in acre-feet	Silt Deposition: Lost capacity, in acre-feet	Silt Deposition: Period, in years	Percentage of original capacity
Elephant Butte	Rio Grande	New Mexico	30,000	2,368,000	220,000	11-1915-1925	9

New Water Supply for Los Angeles

Surveys Now Under Way for Supply from Mono Basin

SURVEYS are being made by engineers of the water department of Los Angeles, Calif., to determine the feasibility of securing an additional water supply from the Mono Basin to tide the city over until a supply from the Colorado River is available. The plan, in brief, according to the Los Angeles Times, from which these notes and the illustration are taken, provides for collecting the water in a reservoir on Rush Creek, its transportation through a tunnel into the Owens Valley water shed and thence into the Los Angeles aqueduct system, via the Owens River. An alternative plan routes the collected water around the south end of Mono Lake, through Adobe Valley and down into the Owens Valley near Bishop, via Fish Slough. It is expected the engineers' report on the project will be completed by the first of the year.

The Mono Basin is just north of Owens Valley, being separated from the valley by a formation of volcanic hills. The water available in the basin is estimated at from 180 to 235 second feet. The streams flowing into this basin from the High Sierras include Parker Creek, Walker Creek, Leevining Creek, Rush Creek and possibly Mill Creek. All plans call, first, for the collection of the flow of the above streams into a common channel. This channel, which will start from Leevining Creek, would consist of a series of open canals and tunnels intercepting the streams. It would deliver the water into a proposed reservoir on Rush Creek, formed by the erection of a 150-ft. concrete dam.

Later the collecting channel that picks up the water from the streams may be extended north beyond Leevining Creek to tap Mill Creek if economically feasible.

An 11-mile tunnel would tap the reservoir on Rush Creek and carry the water under the divide that separates Mono Basin from the Owens Valley, emptying it into Deadman's Creek, which forms the headwaters of the Owens River. The Owens River furnishes the bulk of the flow in the aqueduct, and so once the Mono water gets into the Owens River it is a part of the aqueduct system.

The Owens River flows through Long Valley and into the spectacular Owens River gorge, a very deep chasm 23 miles long. At the head of the gorge it is proposed to erect the Long Valley dam to provide storage capacity and also control the flow of the river through the gorge. The city has an easement on all the lands in the valley that would be covered by water with the building of a 100-ft. dam. Coming through the gorge there is a possible power development of about 86,000 hp. at three possible sites.

The cost of the development is estimated roughly at $30,000,000, this figure including the following:

Water rights: Southern Sierras Power Co., $8,000,000; private holdings, $2,000,000; $6,000,000 to get the water into the Owens River water shed, including cost of tunnels, dam and the like; and another $10,000,000 to buy up the remaining ranch lands and towns in the Owens Valley. In addition, there will be cost of enlarging the aqueduct to handle the combined Owens Valley and Mono basin waters.

Sewage Discharge from Submerged Outlets

Salinity of Body of Water Receiving Sewage an Important Factor in Its Diffusion, Oxidation and Decomposition

By KENNETH ALLEN

Sanitary Engineer, Office of Chief Engineer, Board of Estimate and Apportionment, New York, N. Y.

THE phenomenon of the course and diffusion of sewage discharged from submerged outlets is one that has rarely received close study, although the general results have been long recognized.

In inland cities the phenomena accompanying the discharge of sewage from submerged outlets in lakes and rivers will differ radically from those to be observed in salt water.

The effect of salinity was brought out very clearly in experiments made by the writer for the Metropolitan Sewerage Commission of New York in 1909. Owing to the configuration of the harbor, the flow of upland water brought down by the Hudson River, and the action of the tides, the percentage of sea water was found to average 74.8 at West Bank Light in the Lower Bay and 33.7 in the Hudson River off Fort Washington Point. The extreme readings noted at those points during the year were 93.2 per cent at West Bank Light on Nov. 5, and 0 per cent at Fort Washington Point on April 8. Conditions varied, therefore, from those of fresh water to those of nearly pure sea water.

Several series of experiments were made to learn more of the action of sewage discharged into waters of different specific gravities.

Experiments on Flotation.—Croquet balls were weighed until they balanced in water of a specific gravity of 1.000, and then released in water of known specific gravity at a given depth.* The time required for the balls to rise to the surface was noted with a stopwatch. (See Table I.)

The results, while not entirely consistent, give a fair idea of upward velocities of smooth solids released in waters of different density that will not be reached by a diffusing liquid. Bottles, released in a similar way, rose even more rapidly, on account of their smoother surfaces.

Laboratory Experiments in Diffusion.—A total of 31 experiments was made to observe the action of a dyed sewage or water when discharged from a pipette, or small tube, in waters of different salinity. Alcoholic solutions of eosin and fluorescein and aqueous solutions of bluing, permanganate of potash, and uranine were tried. The dye, especially the bluing, was found to increase the specific gravity slightly, and it was feared that alcohol might affect diffusion. Permanganate of potash was likely to be decolorized by organic matter. It was finally decided to use uranine ($C_{20}H_{10}O_5Na_2$) which, in a strong solution, is a deep red, but becomes a brilliant green on dilution, readily detected in a Nessler tube in a 1:20,000,000 dilution. A dye called "Special Scarlet" was used later and was found to be a very serviceable and less expensive substitute.

These experiments indicated clearly the effect of specific gravity and the way in which a drop or a jet diffused. Some of the forms observed were beautiful as well as interesting: Waves of floc; rings like smoke rings; funnels; and cones and wavy threadlike lines, rising or falling, and diffusing rapidly or slowly. The diffusion of 2 cu.cm. of a 1 per cent solution of uranine added gently to the surface of 200 cu. cm. of waters of varying salinity in beakers and jars began in a few minutes, was complete in an hour with tap water, and took 48 hours in a mixture containing 25 per cent of sea water, while it had not occurred with a 75 per cent mixture of sea water in a week's time. (See Table II.) Salinity, therefore, was shown to have a marked effect on diffusion.

Experiments in Diffusion in the New York City Aquarium.—These experiments, twelve in number, were made to confirm the results obtained in the laboratory before conducting others on a large scale in the open water. The tank was 4 ft. high, 4 ft. wide at the top, narrowing to about 3 ft. at the bottom, and 8 ft. long, with an overflow a few inches below the top. The dye and water were fed from a funnel and by a tube to a nozzle, the depth and direction of which were adjustable. Nozzles of ¼ in., ⅜ in., and ½ in. were used.

Without going into the details of these experiments, some of the results were as follows:

(a) With a horizontal jet a considerable current may be induced at a slight depth without apparent effect on the surface itself.

(b) With a ¼-in. horizontal jet of fresh water in fresh water, under a head of 1.0 ft., the axis of the jet remained horizontal, enlarging in diameter to 3 in. at a distance of 1.25 ft. from the nozzle and to 6 in. at a distance of 3.0 ft. from the nozzle, and then diffusing slowly. After substituting a jet of sewage, the diameter 3.0 ft. from the nozzle was 12 in.

(c) In the case of a ¼-in. upward jet of fresh water at a depth of 3.0 ft. in fresh water under a head of 2.5 ft., the jet formed a concave cone 5 in. in diameter 1.0 ft. from the nozzle and spread in a thin layer at the surface. By the end of 5 min. diffusion was quite uniform to a depth of 1.5 ft.

(d) With a ½-in. horizontal jet of sewage in fresh water near the bottom of the tank, 3.4 ft. below the surface and under a head of 0.15 ft., there was a gradual descent of the jet to the tank bottom which it covered with a blanket about 2 in. thick, with very little diffusion, in 3 min. The temperature of the sewage was 62° Fahr., with a specific gravity of 1.001. The temperature of the water was 61° Fahr., and its specific gravity was 1.000.

(e) With a ½-in. jet (nearly horizontal) of sewage in harbor water, at a depth of 3.3 ft. and under a head of 0.15 ft., a temperature of sewage 62° Fahr., specific gravity, 1.0015, and a temperature of water, 58° Fahr., the effluent rose promptly in an upward curving cone, reaching the surface in 1 min., where it spread out. At the end of 3 min. the supply of dye was cut off and by the end of 5 min. there remained but a thin green layer at the surface.

(f) For a ¼-in. horizontal jet of sewage in harbor water, as in Result (e), under a head of 1.0 ft., the diameter in a plane 1.0 ft. above the nozzle was 8 in. The horizontal component of the jet did not appear to affect the time taken to reach the surface.

Table I—Experiments to Determine Upward Velocity of Smooth Solids

Experiment No.	Number of tests	Specific gravity of water	Vertical distance traveled, in feet	Average velocity, in feet per second
1	13	1.0215	1.47-1.51	0.500
2	10	1.016	1.70	0.455
3	15	1.007	1.62	0.252
4	15	1.009	1.62	0.301
5	4	1.0195	10.0	0.655
6	10	1.0215	10.0	0.49

*The salinity of sea water varies in different parts of the ocean, but for this region chlorine of 18,000 parts per million, corresponding to a specific gravity of 1.025, was assumed as constituting 100 per cent.

(g) With a ¼-in. upward jet of sewage in harbor water, at a depth of 2.5 ft., and under a head of 1.0 ft., the sewage rose promptly to the surface with little diffusion and then spread in a thin layer. The diameter 2 ft. above the nozzle was 6 in.

(h) At a ¼-in. downward jet of sewage in harbor water, under a head of 1.0 ft., the jet rose as a column of greater diameter and with more rapid diffusion than in Result (g) and spread at the surface. Diffusion was increased materially by a slight agitation of the water.

The results of these experiments are generally confirmed by the work of the authors and by a similar apparatus, but their analysis has been carried to a point where the path of a jet of fresh water in sea water may be more closely predicted.

Experiments on Diffusion in New York Harbor.—Nine experiments were made by placing a dye in the surface water of the harbor, or at sewer outlets, to observe the rate at which sewage might be expected to become diffused and dispersed under different conditions. These were followed by 21 experiments to observe the result of discharging dyed water at various depths and locations in the harbor.

In three experiments at the outlet proposed at that time for the Bronx Valley Sewer, in the Hudson River, off Mount St. Vincent, dyed water was pumped at rates of 17 to 25 gal. per min., to depths varying from 5 to 25 ft. through a 1¼-in. hose. The velocity of the river water varied from 0 to 3 ft. per sec., and its specific gravity varied from 1.010 to 1.013. The detection of dye at the surface was uncertain at slack water from depths greater than 16 ft., or in a current of 2½ ft. per sec. from depths greater than 9 ft.

Nine similar experiments were made at various points in New York Bay, Gravesend Bay, and the Upper East River. These indicated that:

(a) With a difference in specific gravity of 0.004, dyed water will rise in quiet harbor water from depths of 10 to 26 ft. at a mean rate of 0.10 to 0.14 ft. per sec., and be visible at the surface.

(b) With a difference in specific gravity of 0.004½, it will rise from a depth of 18 ft. at a mean rate of 0.17 ft. per sec. and be visible at the surface.

(c) With a difference in specific gravity of 0.016, it will rise from a depth of 27 ft. in a current of 1½ ft. per sec. at a mean rate of about 0.10 ft. per sec., and be visible at the surface.

(d) In moderate currents dyed water may be expected to be visible at the surface if discharged at depths of 15 to 20 ft., but that the rate of ascent is variable. The limit from which it can be discovered under the most favorable conditions appears to be about 40 ft. In sea water (specific gravity, 1.021½), with a current of 0.3 ft. per sec., diffusion is very gradual at first, but proceeds more rapidly later.

Two similar experiments, but on a larger scale, were made in the Upper Bay, near the site of the Passaic Valley Sewer outlet off Robbins Reef, which has since been built.

In the first experiment, 16,500 gal. of a 1:2,750 solution of uranine in tap water was discharged 40 ft. below the surface through a 2½-in. hose, at a rate of 205 gal. per min., giving a velocity of 14 ft. per sec. The specific gravity of the harbor water varied from 1.0115 to 1.0135.

In the second experiment, 56,000 gal. of tap-water containing 290 lb. of uranine, forming a solution with a specific gravity of 1.003, was pumped from a pontoon through an 8-in. pipe, at a rate of about 2,320 gal. per min., or with a velocity of 14.8 ft. per sec., to a depth of approximately 40 ft., the pontoon and discharge pipe rising as the experiment progressed. The specific gravity of the harbor water was 1.015, and the velocity of its current, as observed by submerged floats, averaged: 0.45 ft. per sec. at a depth of 3 ft.; 1.03 ft. per sec. at a depth of 20 ft.; and 2.85 ft. per sec. at a depth of 50 ft.; from which the mean velocity at the point of discharge was taken as 2.2 ft. per sec.

In spite of these large volumes no evidence of the discharge was observed in either case, although it had been detected once before in one of the smaller experiments at this point and at the same depth. The inference was that diffusion occurred rapidly due to subsurface currents at the time of the larger experiment, and that the rise of sewage to the surface probably depends more on the velocity of such currents than on the volume of sewage discharged.

Table II—Diffusion in Waters of Different Salinity*

Liquid added		Top water	Sewage	Sewage
Dilution of uranine solution		1:100	1:1,000	1:10,000
Specific gravity of liquid added		1.000	1.001½	1.001½

It is clear that salinity of a body of water receiving sewage is an important factor in its diffusion, as it also is in its oxidation, its effect on precipitation, its decomposition, its general appearance, and its accompanying odors. The sewage of the city of Washington, D. C., discharged in 30 ft. of fresh water in the Potomac River and that of Hamburg, Germany, discharged at a depth of 30 ft. in the Elbe, is difficult to discern at the surface, while that from the Boston and New York outlets forms a field on the surface that is often clearly visible, well defined, and extensive. It was noted in the New York experiments with dyes that the edge of the field on the windward side was most clearly defined, while the more rapid diffusion took place on the leeward side.

From what has been said it is evident that diffusion is promoted by locating inlets in deep water of low salinity, but having a high velocity of flow. Discharge should be horizontal and from multiple outlets. The submerged outlets from Deer Island in Boston Harbor, with fourteen horizontal orifices, and the one hundred and fifty outlets of the Passaic Valley Sewer, in which the upward-flowing stream is dissipated by spiral flanges, are excellent examples of effective diffusion and dilution of an effluent in salt water.

As the visibility of sewage fields in calm weather is largely due to the oily surface film known as "sleek," it is obvious that for the sake of appearance, oily wastes should be kept out of effluents so far as practicable: First, by control and treatment at the source of industrial wastes of this nature; second, by providing municipal collection of crankcase wastes from garages; and, third, by installing skimming tanks on the line of outfall sewers. Other points that might be emphasized are the very great effect of turbulence of current on diffusion, and the variable effect of winds on the shape and extent of the sewage field.

Table III shows how the sewage discharged at the Deer Island and Moon Island outlets in Boston Harbor concentrates near the surface, as indicated by the increasing salinity or percentage of sea water and saturation with dissolved oxygen with increasing depth.

Pipe Line Bridges; Methods of Covering Pipe and Costs

In the last two years the progress made in the installation of water mains in the Baltimore County Metropolitan District of Towson, Md., necessitated the crossing of three railroad right-of-ways, which were spanned by highway bridges, and due to the fact that the railroad company's and highway's engineers refused to grant permits for the installation of these water mains on the floors of the existing bridges, separate trusses were constructed to carry the mains across. In a discussion at the 1929 conference of the Maryland Water and Sewerage Association A. F. D. Domenics gave the following information regarding this work.

Table I

	79-Ft. Span	126-Ft. Span*	96-Ft. Span
Size pipe, inches	10	10	12
Type of covering	Box and Saw-dust	Box and Saw-dust	Felt and Galv. Iron
Cost of truss and extra steel	$ 846.56	$1,518.69	$1,425.00
Piers	----------	----------	487.50
Cost of laying pipe	30.02	62.40	195.84
Cost of covering	178.86	171.60	499.86
Total cost of job, exclusive of pipe and fittings	1,055.44	1,752.69	2,608.20
Cost per foot, dollars	13.36	13.91	27.16

*The actual length of this truss is 66 ft., although the total length of the crossing is 126 ft. Three brackets were placed 5 ft. apart on the side of the existing highway girder, so as to carry the pipe projecting from each end of the truss.

The Trusses.—The trusses that were accordingly designed and built were of the Warren Type, and were 79, 66 and 96 ft. in length. The first two mentioned were built and hauled to the site and placed on the existing abutments in one piece, but the latter, due to its length was hauled to the site in two sections, and was riveted together in the field and placed in position in one piece. The water mains on these trusses rest on 2x12x¾-in. plates placed equally along the span and are bolted on these plates by ¾-in. U-bolts. To safeguard against any overturning effect, the 66 and the 79-ft. trusses were attached to the existing highway bridges by five straps, three on top chord and two on bottom. These straps were riveted onto the truss, but on the existing bridges the holes on the straps are slotted and bolted to the structure. The reason for slotting is to transmit as little vibration to the truss as possible and at the same time hold the truss in place. The pipe fittings at both ends of the trusses are held secure from blowing out by pipe clamps. Lead was used for jointing material on the three jobs, and there also was placed a sleeve near the center of the crossing to provide for expansion and contraction in the main.

Protecting Pipe from Freezing.—Two methods of protecting pipe from freezing have been used by the department. The first is by encasing the pipe in a wooden box with saw-dust. The box coverings are built as follows: Frames made of 2x4-in. studdings are placed 3 ft. apart around the pipe. On the sides of these frames are nailed 1-in. boards and on the bottom 2-in. boards; this forms the box. The box is then filled with saw-dust, so that, the pipe has at least 4 in. of the material on sides and bottom. The cover is made of 1-in. lumber and then the entire box is covered with asphalt roofing paper, in order to keep the rain from seeping in and wetting the saw-dust.

The second method used is as follows: The pipe is covered with two layers of 1-in. hair felt, each layer firmly secured with copper wire. Between each layer of hair felt is placed roofing or asphalt paper. On the last job (on a bridge crossing a stream), the asphalt paper was sewed on to the hair felt and a great deal of time and labor was saved in placing this around the pipe. A metal casing of galvanized sheet iron is then placed around the pipe and this is held in place by ⅛-in. steel bands 1½ in. wide placed 2 ft. apart. The entire casing is then given two coats of paint to conform with the color of the bridge. Although the saw-dust method is much cheaper and answers the purpose, it is believed that the latter method is more satisfactory and the appearance of the complete job is much neater.

The cost of these jobs complete, exclusive of cost of pipe and fittings, is shown in Table I.

Marginal Lands for Impounding Reservoirs

In a discussion by W. H. Dittoe and G. Gale Dixon, respectively chief engineer and deputy chief engineer, the Mahoning Valley Sanitary District of Youngstown, O., in Vol. 93, 1929 Transactions of the American Society of Civil Engineers, the following table showing the acquisition of land about various important reservoirs is given:

High Manganese Effluents from Idle Filters

Experimental Work at Columbia Heights Filtration Plant Shows That Manganese Is Redissolved from Sand of Idle Filters

By A. C. JANZIG and I. A. MONTANK

Bacteriologists and Chemists, Columbia Heights, Filtration Plant, Minneapolis, Minn.

IN reviewing the analytical data for the past 2½ years at the Columbia Heights filtration plant, we found that the monthly composite samples of the plant effluent yielded manganese, in several instances, in amounts ranging from 25 to 200 per cent greater than that found in the raw water samples. Although these amounts were far below the tolerable limits, the increase was such as to suggest another source of manganese. Since the raw water contained relatively small quantities of the element, it seemed logical, to assume that some stage in the treatment of water was responsible for the increase of manganese. Because it is well known that manganese is deposited and retained on the sand grains of filters this seemed the most probable origin of its increase.

In this work we are dealing with a source of contamination in the plant effluent brought about by the resolution of the manganese oxides from the sand grains of idle filters. This condition is possible even though a raw water supply may contain only small quantities (less than the tolerable limits) of manganese compounds; because a gradual accumulation of the element takes place in filter beds where it may again be redissolved when conditions become favorable.

Experiments at Columbia Heights Filtration Plant.—The Columbia Heights filtration plant contains two sets of rapid sand filters. Filters numbered 1 to 16, inclusive, are as a general rule in service a greater part of the time, while the set of filters numbered 17 to 24, inclusive, have been used only in cases of emergency during the past two years. The latter filters had been out of service for many months and were utilized as a means of determining the extent to which manganese redissolves from the filter beds while in contact with wash water over a period of time. While remaining idle, the filters 17 to 24, inclusive, were washed periodically, about once every month during the winter months and more frequently during the warmer weather. During the month of May they remained idle, in contact with about 20 in. of wash water covering the surface of the sand. Twenty-five samples of water taken from the surface of these filters (about 1 in. above the sand) had a manganese content greatly exceeding the tolerable limits

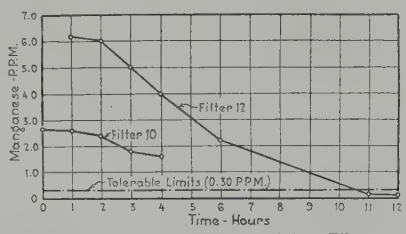

Fig. 1—Manganese in Effluents of Two Filters Idle 38 Days and Operated at a Rate of 1.5 M. G. D.

and in one sample 15.0 p.p.m. manganese were obtained. Four of the filters had been treated with 2 p.p.m. copper sulfate in order to check the growth of algae which had been troublesome in the past. In Table I the results obtained from these four treated filters, are compared with four untreated filters. It will be noted that the treated filters gave a lower manganese content than the untreated filters.

An additional matter of interest in this connection was to determine to what extent biological action influenced the dissolved oxygen content and the hydrogen-ion concentration. The water as applied on these filters had dissolved oxygen content of from 7.0 to 8.0 p.p.m. and an initial pH of 6.7. After the 31-day idle period samples of water from 3 filters gave zero dissolved oxygen, while the samples from the remaining five gave values below 1.5 p.p.m. The hydrogen-ion concentration changed to a minimum of pH 7.1 and maximum of pH 7.6.

The next problem was to determine whether or not a filter which had remained idle and then washed would deliver manganese when placed into service. Hourly samples were taken from the effluents of two filters that had been out of service five weeks and were analyzed for their manganese content. The results obtained, as indicated in Fig. 1, show that these filters delivered water with a manganese content far in excess of the amounts delivered by filters in regular service. It will also be seen that the curves represent values greatly exceeding that of the tolerable limits.

In a series of samples an attempt was made to correlate the manganese content with the degree of reaction that takes place when the o-tolidine reagent is used. Table II shows the extent to which manganese in parts per million is related to the false chlorine readings in parts per million. Samples 2, 4, and 6 vary considerably in manganese concentration, but all apparently react to the same degree with o-tolidine reagent after a 10-minute contact period. Sample 2 exceeds that of sample 5 in manganese content by more than 1.5 times, yet the same amount of false chlorine is produced by both. In a comparison of sample 1 with sample 8, it is noted that a difference of 30 times in the manganese content exists while the difference in the false chlorine obtained amounts to only 7 times. The 50-minute contact period with the o-tolidine reagent gave values from 0.01 to 0.04 p.p.m. higher than that of the 10-minute period. However, one sample failed to show an increase of false chlorine.

Discussion.—Early investigators have attempted to explain the deposition and resolution of manganese in filter sands on the basis of physico-chemical action rather than by biolysis. Able support of the biological theory in bringing about a change of manganese from the soluble to the insoluble form and vice-versa, is presented by the independent work of Baylis and Kühr. Baylis demonstrated by laboratory experiments that the deposited manganese on sand will redissolve. He used samples of sand taken from filter beds which were covered with slime produced by bacterial growth, and submerged them in water for a week or more. The solution obtained from this sand contained about 10 p.p.m. soluble manganese. He repeated this experiment a number of times, and in every case when the sand was covered with slime there was an increase of soluble manganese. He considers that in covering the deposited manganese with slime, the bacteria

Table I—Manganese in Surface Samples from Treated and Untreated Idle Filters. Results in Parts per Million

*Using o-tolidine made according to Standard Methods, 1925 edition.

produce conditions favorable for its being thrown into solution. Kühr, on the other hand, gives experimental evidence that manganous compounds can be oxidized to manganese dioxide by microbial growth. He demonstrated this fact by inoculating the surface of a solid, synthetic media containing manganous carbonate with bacteria and fungi as found in raw dune water and in the mud of rapid sand filters. The cultures developed a typical dark brown manganese dioxide. He concludes that "by the biological oxidation process the dissolved manganous compounds can be transformed into undissolved manganese dioxide, and that inversely by biological reduction, which always takes place in anaerobic processes, undissolved manganic compounds can pass into dissolved ones."

The fact that soluble manganese is retained as manganese oxides in active filters and redissolved in idle filters is supported by the results obtained in the experiments conducted. Soluble manganese found in 25 samples of water taken from the surface of idle filters seems to confirm the biological resolution theory, and the negligible amount or absence of manganese in the effluents of filters in regular service adds evidence to the known fact that retention of manganese compounds as insoluble manganese oxides occurs on sand grains. In Table I a comparison is made between the amount of soluble manganese obtained from a set of treated and a set of untreated filters. Probably this difference would have been even more marked had the treated filters received frequent and larger doses of copper sulfate. This phase of the subject will require further study in order that more definite and complete information can be secured. A suggestion is also seen for further investigation in the use of other sterilizing agents which would be applicable for filters out of service. If no subsequent operating difficulties arise another means of preventing the resolution of manganese may be found in permitting filters to remain dry during their idle period.

The conditions were favorable for anaerobic decomposition in the water on these idle filters is evident since the dissolved oxygen content in five filters was very low, and in three of the filters it was zero. Originally the applied water had a dissolved oxygen content of about 7.5 p.p.m. The logical deduction to be drawn here is that the depletion of oxygen was due to aerobic biological activity, since the loss of oxygen can be explained in no other way. Another condition probably brought about by biological action is the change found in the hydrogen-ion concentration from a pH of 6.7 in the applied water to an average of about 7.3 at the end of the 31-day period. It is possible that the end products of anaerobic decomposition increased the pH above the neutral point, as it is known that ammonia may be evolved from such decomposition. It would seem, therefore, that the resolution of manganese did not take place because of the presence of an acid condition.

The most interesting observations made are those represented by Fig. 1 showing the delivery of soluble manganese from two filters, 10 and 12, which had been idle for more than five weeks. The filters had been thoroughly washed and filtered to waste for 15 minutes before being put into service. At a filtration rate of 1.5 million gallons per day, the effluents of these filters continued high in manganese concentration over a period of several hours. Five samples were taken from filter 10 and analyzed. It delivered an initial manganese concentration of 2.7 p.p.m. Out of the seven samples analyzed from filter 12 the initial sample showed manganese to the extent of 6.2 p.p.m. In the latter filter, a sample analyzed after the second hour showed a slight decrease of manganese, and the subsequent hourly samples showed approximately 1 p.p.m. decline in the manganese content. A normal condition with respect to manganese was not obtained until a period of more than 11 hours had elapsed. The initial yield of manganese for filter 10 is only about one-half that of filter 12. Although more samples should have been taken from filter 10, it would seem from the curve plotted and also by interpolations that the period of time necessary for this filter to reach a normal output of manganese would be at least 8 hours.

In addition to the samples from the two filters shown in Fig. 1, one sample was obtained from filter 9, which had been out of service 42 days. This filter yielded a manganese content of 0.40 p.p.m. after it had been in operation nearly 7 hours. The delivery of a high manganese content does not result from filters which are in continuous operation, as evidenced by the analysis of the effluents of normal filters. The average manganese content of these filters, during the same period of time, rarely exceeded 0.05 p.p.m., and approximately 50 per cent of the time was zero.

Since the effluents of the idle filters delivered such an excessive amount of soluble manganese, it was desirable to know whether or not the plant effluent would show an increase over the monthly average. The monthly composite samples of the plant effluent for the years 1927 and 1928 gave a maximum manganese content of 0.06 p.p.m., a minimum of 0 and an average of 0.02 p.p.m. Two samples of the plant effluent were taken at about 22 and 29 hours after filters 10 and 12 were put into operation. It was calculated that sufficient time had elapsed to allow for a detention period in the clear water reservoir so that a representative sample could be secured. Analysis of the first sample, taken after 22 hours, showed a manganese content of 0.10 p.p.m. and of the second, at the end of 29 hours, of 0.08 p.p.m. While these figures do not represent amounts that are likely to cause trouble, it can be seen that a potential danger exists when a number of idle filters are put into service at the same time.

The reaction of manganese compounds with the o-tolidine reagent produces the characteristic color that free chlorine produces with the same reagent. In Table II no direct relationship was found to exist between the amount of manganese in parts per million and the amount obtained in false chlorine readings. Campion at the Barberton plant in Ohio gives experimental evidence to show that false chlorine readings reach their maximum value when the oxidation of manganese has gone to completion. Apparently the degree of oxidation in which the manganese exists is a factor in the production of the yellow color with o-tolidine. This may explain the lack of correlation in the values tabulated in Table II. Forsberg made the interesting observation that "Water containing manganese as manganic hydroxides gives the same reaction with o-tolidine as chlorinated water, irrespective of whether a water, alcohol, sulphuric acid or hydrochloric acid solution of the reagent is used." Aside from the deduction made from Table II, a point of interest is found in the fact that the majority of the false chlorine readings produced by manganese compounds increased with time, while on the other hand it is a well known fact that in the test for free chlorine the converse is true.

From a consideration of the bio-chemistry of the subject the deductions are that the deposition of manganese is caused by a biological oxidation process; and inversely, the biological reduction induced by anaerobic decomposition converts manganese oxides into the soluble manganous compounds. The layer of manganese oxide deposit formed on the sand grain serves to attract more soluble manganese, which in turn is oxidized by the aerobic microbes to the insoluble form. The process is continued until finally the sand grains are covered with many layers of manganese oxide.

In the case of incrustations formed on the sand grains of filters where alum is used as a coagulant, there exists, in addition to an insoluble manganese oxide and bacterial jell, aluminum hydroxide. The two latter substances may occur in intimate combination with the manganese oxide, or they may occur in alternate layers with the manganese oxide. The writers believe that when anaerobic decomposition has rendered the manganese oxide soluble, the coatings of bacterial jell and aluminum hydroxide probably act in a manner similar to that of a semi-permeable membrane, delaying the rate of diffusion of soluble manganese from the sand grain. It is therefore reasonable to suppose that, when a filter is washed, only the outer soluble manganese com-

pounds are rapidly removed. Following this reasoning it is probable that after the filter is placed in service, the hydrostatic pressure created is sufficient to draw the soluble manganese out from the inner layers of the same grain. This explanation may account for the delivery of a high manganese content over a period of 8 hours or more by idle filters which are again put into service.

Summary.—Analytical data are presented to show that manganese is redissolved from the sand of idle filters.

It is demonstrated that the effluents of idle filters will deliver a high concentration of soluble manganese, and that this condition may continue for a number of hours.

No direct relationship is found between the amount of manganese present in a water and the amount of false residual chlorine produced with o-tolidine reagent.

The information obtained thus far indicates that biological action is an important factor in the process of redissolving manganese.

A suggestion for the prevention of the resolution of manganese in idle filters may possibly be found in the proper use of copper sulfate.

Contamination by Consumers' Water Uses

A New Viewpoint of Possible Water System Pollution

By S. B. MORRIS
Chief Engineer, Water Department, Pasadena, Calif.

IN reviewing water works literature, I do not recall any papers having been presented or restrictions drawn regarding piping and use of water by consumers after water has passed through the meter to their private premises. Before discussing the general possibility of such contamination, I should like to recite a few instances of contamination which have come under my observation.

How Lime Got Into the Mains.—One day we received a complaint of excessive lime in the water of a limited district. Upon investigation we found that a water softening plant where water was treated for boiler feed purposes, was the cause of trouble. An elevated tank with pressure normally much less than that on the public water system stored this heavy dose of lime. During an emergency shutdown of the water main, a check valve on this line failed to operate and the lime water contents of this tank was drawn into the distributing system.

Cafeteria Has Connection with Swimming Pool.—In another instance, we received complaint at a school cafeteria that excess chlorine in the water was discoloring the silverware. We knew this could not be the case, as the territory involved received no chlorinated water. Upon investigation, we found that an ortho-tolidin test showed about one-tenth part per million of free chlorine at the cafeteria, whereas a test from a fire plug directly connected to the city main adjoining the school showed no free chlorine. It was apparent that the cafeteria was receiving its water from a connection to the swimming pool circulation line, which proved to be the case. Apparently a serious epidemic was only averted by continuous excess chlorination of the swimming pool water.

Sewage Backs Up Into Domestic Water System.—At another time, we received complaint of sewage odor in the showers at a public swimming pool. We immediately investigated and found the complaint justified. There was a sewage pumping plant about 500 ft. from the swimming pool. At this plant horizontal, centrifugal pumps were used with automatic, intermittent operation raising the sewage from a concrete storage well up to the public sewers about 100 ft. higher in elevation. The sewage pumps were located above the elevation of the sewage in the storage well necessitating pumps operating under a suction. The pump operator had had so much difficulty in priming these pumps that he installed a hose connection between a garden valve connected to the public water supply and used this hose to prime the pumps. Finally he had wired one end of this hose to a stop cock on top of the pump. At the time of the complaint, he had forgotten to close the stop cock and the pressure on the sewage pump line being in excess of the domestic water supply, caused accrued sewage to back up into the domestic water system actually contaminating the shower baths at the swimming pool.

How Air Got Into the Water.—In another instance, we received complaints of air in the water over a considerable area. For several months we were unable to discover the source of air the consumers complained of. Finally, we found a water meter which registered backwards. Investigation showed that the machine shop and garage furnished by this service had an air compressor and air storage tank. In order to diminish the water bills, the proprietor of this shop had blown water back through the water piping, reversing the water meter while the air passed off into the water distributing system. Probably no contamination occurred through this operation, but it illustrates the possibilities of water being passed through the meter into the distribution system.

From time to time new industrial or sanitary equipment offering opportunities of contamination comes upon the market. The water utility has no direct knowledge of what equipment or piping is being installed by the individual consumer within his private premises. How is this matter to be controlled? I believe the only way is by co-operation with the building and plumbing inspection departments of the city.

Sanitation Department Urged for New York City

The Merchants Association of New York City has opened a campaign in behalf of the proposed charter amendment which would create a new city department of sanitation for the city of New York.

Action by the association followed a study of the subject by the organization's committee on sanitation, public health and water supply, of which Prof. Olin H. Landreth is chairman. Letters were sent to thirty-eight other organizations. They declared in part:

"The measure relates to a vital matter—the health of the people of New York. The planning of adequate and comprehensive sewage and garbage disposal systems which will free our rivers and beaches from the filth with which they are now polluted, and thus rendered a menace to the thousands who use them, is one of the gravest problems faced by our city. Attempts to deal with this subject in the past have been fruitless of any large accomplishment.

"The state of New Jersey has recently instituted with the Federal government an action to prevent the dumping of garbage at sea—alleged to be a contributing cause of pollution affecting not only the New York but also the New Jersey beaches. The work of providing adequate disposal plants in order to anticipate the intolerable situation which might arise if the Federal government should put a stop to this practice should be speeded up.

"Sanitation experts and others who have studied this matter believe that existing agencies are inadequate to deal with the problem. Those who have given most thought to the subject are in agreement that the creation of a department of sanitation, such as is now proposed, offers the greatest expectation of obtaining expeditiously a sound and comprehensive plan of relief."

Sewage Sludge as Fertilizer

Sludge from Present Sewage Plants Could Furnish 8,000 to 10,000 Tons of Nitrogen Yearly

By WILLEM RUDOLFS

New Jersey Agricultural Experiment Station, New Brunswick, N. J.

HUMAN wastes and wastes from certain industrial processes contain considerable quantities of plant-food, which under ordinary conditions are lost. If the sewage is not treated, the material finds its way into streams and water courses; and in those cases where sewage disposal plants are present, the organic solids are retained as a sludge.

There are two general methods of sewage purification; namely, settling of solids followed by anaerobic digestion, and oxidation by forcing air into sewage. In both cases quantities of sludge are left behind. The sludges contain appreciable quantities of nitrogen and some phosphorus and potash, but the chief value of the sludge for fertilizer is in its nitrogen content.

There is at present only one sewage disposal plant in this country—the Milwaukee activated sludge sewage plant—where sludge is commercially marketed on a large scale. In a number of instances the sludge is locally sold for a nominal sum to farmers in the neighborhood. In the majority of cases the sludge is either buried or used for filling-in low places.

Composition of "Milorganite".—The product sold by Milwaukee under the trade-name of "Milorganite" has been dried, finely and evenly ground, and contains 5 per cent or less moisture.

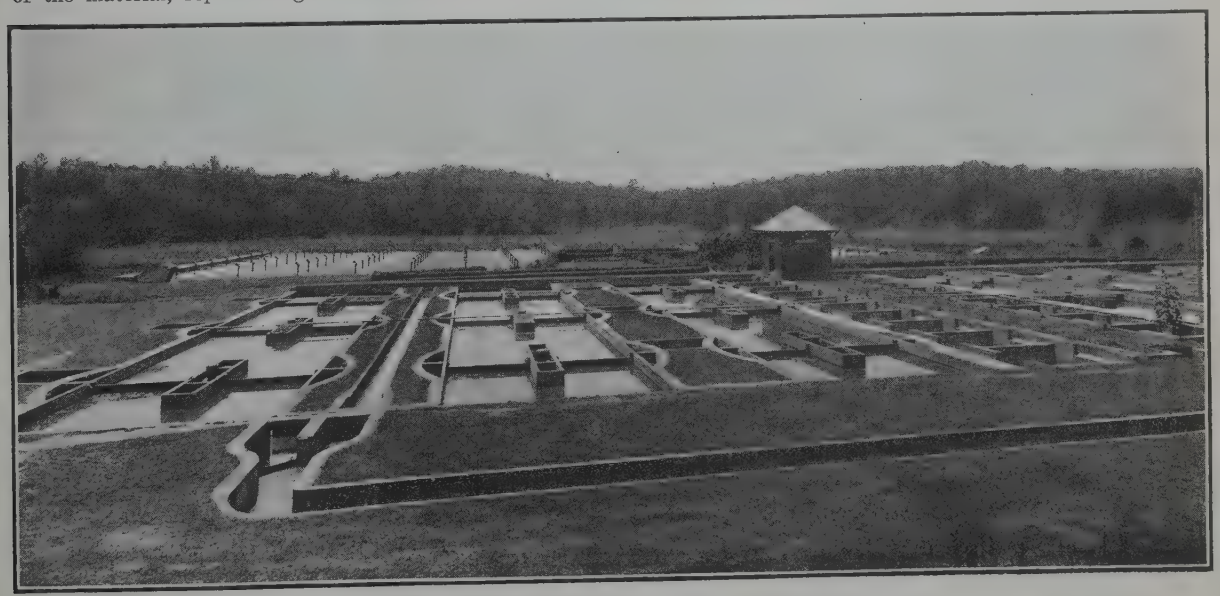
Kadish (2) has published an analyses of the material, representing 145 carloads shipped during a part of 1927. The composite sample contained:

	Per Cent
Total nitrogen	5.42
Water soluble organic nitrogen	0.30
Nitrogen insoluble in neutral permanganate	0.71
Active nitrogen by alkaline permanganate	3.22
Total phosphoric acid	3.08
Available phosphoric acid	2.43

Analysis of Plainfield Sewage Sludge.—There are only a few activated sludge sewage disposal plants in the country as compared with disposal plants where the sludge is digested anaerobically. Sewage sludge looses part of its nitrogen content in the course of digestion, probably most of it as nitrogen gas. As examples of the fertilizing value of fresh (undigested) solids, partially decomposed material, and fairly well-digested sludge, analyses of material obtained from the Joint Sewage Disposal Plant of Dunellen, Plainfield, and North Plainfield, N. J., are given in Table I. The analysis used for illustration show a rather high initial total nitrogen content. It usually runs at this particular plant between 3.50 to 4.00 per cent nitrogen. An average of a number of analyses shows 3.62 per cent total nitrogen in the fresh solids and 2.70 per cent in the ripe (digested) sludge.

Analysis of Sludge from 14 Cities.—At the request of the author, a number of superintendents and engineers in charge of sewage disposal plants in the country forwarded samples of sludge to our laboratory for analysis. The pertinent results together with some remarks are given in Table II. The percentage ash of the materials varies considerably. There are two reasons for this variation; namely, inorganic trade wastes present in the sewage, and the degree of decomposition accomplished. Domestic wastes settling out at a sewage treatment plant contain from 20 to 25 per cent ash. These solids, kept for a considerable number of days in digestion tanks, decompose under anaerobic conditions, producing large quantities of methane, some carbon dioxide, and some nitrogen gases (CH_4, 70 to 75 per cent; CO_2, 18 to 25 per cent; N, 3 to 10 per cent). The amount of ash remains constant but the percentage increases in relation to the percentage decrease of organic matter, with the result that well-digested sludge contains approximately 50 per cent ash. When inorganic trade wastes are received, the initial ash content varies from 25 to as high as 50 per cent, according to the amount of trade waste present.

The nitrogen content of the sludge depends upon the same two factors. The better digested, the lower the nitrogen content; and the more trade waste, the less the original percentage nitrogen, except when slaughterhouse, tannery, and such wastes are treated. If less than 2.5 per cent total nitrogen is present in the digested sludge there



Intrenchment Creek, Sewage Disposal Plant, Atlanta, Ga.

is ordinarily inorganic trade waste present.

The sewage plant operator wishes to produce a well-digested material, because this material will dry rapidly and has no odor, but in doing so, the fertilizing value of the sludge decreases.

The amount of dry domestic solids produced per capita per day is fairly constant. A large number of analyses shows it to be in the neighborhood of 70 gm. per capita daily. With trade wastes present the amounts rise sometimes as high as 200 gm. per person per day. The amount of solids retained at a domestic sewage treatment plant varies from 30 to 65 gm. per capita per day, depending upon the type of treatment plant. In the aggregate the quantities of sludge produced are enormous. Milwaukee alone, for instance, produces approximately 25,000 tons of dry sludge, which must be handled in a wet condition, requiring machinery to treat 500,000 tons sludge. Where the sludge is digested, the quantities are lower. Fuller and McClintock (1) state that at present about 15 per cent of the sewage is treated in this country. The total dry solids in the sewages received at these plants is between 400,000 and 500,000 tons per year. Assuming a minimum average of 2 per cent nitrogen in the sludge, the annual loss of nitrogen amounts to from 8,000 to 10,000 tons for the treated sewage only. Most of this could be used as fertilizer, since it is already collected at sewage disposal plants.

From 150,000 to 200,000 tons of nitrogen, as a conservative estimate, present in sewage is annually lost by discharging sewage into streams and water courses, and by wasting the sludges.

Summary.—The nitrogen content of sewage sludges varies with the type of treatment. Aerobically treated sewage sludge contains about 5 per cent, and anaerobically treated sludge averages about 2.25 per cent nitrogen. Only one sewage treatment plant markets its sludge on a large scale; at a number of places the sewage sludge is given away or sold for a small nominal sum. It is estimated that from 150,000 to 200,000 tons nitrogen is lost annually. Based upon analysis of a number of sludges from different sewage plants,

Table I—Analysis of Plainfield Sewage Sludge

	Fresh solids, per cent	Partly digested solids, per cent	Fair digested solids, per cent
Total N	4.81	3.98	3.55
Insoluble N	4.14	3.61	3.41
Soluble N	0.67	0.37	0.14
NH_3-N	.....	.....	0.09
Soluble organic N	.....	.....	0.05
Active insoluble N	0.98	1.89	1.57
Inactive insoluble N	1.16	1.71	1.84

Sewage Treatment Plant at Milwaukee, Wis., During Construction

it is estimated that from 8,000 to 10,000 tons nitrogen per year could be saved at present.

Acknowledgment.—The above is a paper of the Journal Series of the Department of Sewage Disposal of the New Jersey Experimental Station. It is reprinted here from Soil Science.

Sewage Plant Operations at Milwaukee

The following notes on the operation of the activated sludge plant of Milwaukee, Wis., are taken from the recently issued 1928 report of the common council on the activities of the city departments, boards and commissions:

Throughout the year 1928 the sewage disposal plant was operated at its full capacity. At the beginning of the year, the average amount of sewage treated was 85,000,000 gal. for 24 hours. Due to additions mainly in the suburban sewer system, the quantity treated rose during the year to an average of 95,000,000 gal. per 24 hours. During each day there is a peak load on the plant which amounts to from 130 to 140 million gallons in 24 hours.

During 1928 the total time of bypassing due to storms was 7.8 per cent of the total number of hours per year. Therefore, 92.2 per cent of all the sanitary sewage produced in the metropolitan district during the year was purified, the balance being taken care of by dilution in the large basin of Milwaukee bay.

Sales of Fertilizer.—The plant removes from the sewage all the suspended solids, which are converted into a commercial fertilizer and sold. The total output of the plant during the year amounted to 33,000 tons of fertilizer for which approximately $600,000 were received.

The demand for Milorganite, the fertilizer produced in the sewage disposal plant, has always been greater than the supply. About 70 per cent of the output is shipped to fertilizer manufacturers who blend it with other ingredients such as phosphates and potash and sell this product for use mostly in the states that grow cotton and tobacco. The remaining 30 per cent is sold for use directly without the admixture of any other material. This unmixed Milorganite is especially valuable for the growing of fine lawns and for general garden use. Most of this part of the output goes to golf courses, park boards, and other places where fine lawns are maintained. A considerable amount is sold in 100 pound bags to the gardeners of Milwaukee and the surrounding suburbs. These local sales in 1928 brought a return of approximately $10,000. The retail sale price is $1.50 per 100 lb. bag.

The research work was pursued vigorously during the year and has furnished valuable information which will be used in the plan of the necessary extension. The four small plants in the testing and control station were continually operated, and the results obtained were analyzed and tabulated.

During 1928 an elaborate cost keeping system was worked out which will be put into service at the beginning of 1929. This will make it possible to determine accurately the cost of every phase of plant operation.

The intercepting sewer system was somewhat extended during the year.

Elimination of Odor.—During 1928, the method used in treating odor, introducing chlorine gas into the dryer discharge, proved very successful. Very few odor complaints were received during the year, and these were carefully traced to their source. Some of the complaints were clearly caused by odors emanating from sources other than the sewage disposal plant, but several were found to be well founded and caused by faults in the operation of the dryer equipment. Continued experiments with this equipment has resulted in an almost entire absence of complaints.

When the chlorine treatment of dryer gases was introduced, it was considered only a temporary expedient, and other methods of deodorizing were investigated. It was found that chlorine was superior in its effect to other methods and lower in its operating cost. During the year the total cost of chlorine used for deodorizing was almost exactly $10,000.

Plans for Plant Extension.—The gradual increase in the amount of sewage coming to the plant points to the necessity of plant extension in the near future. Another factor contributing to this is the rapid development of the suburban territory lying within the metropolitan district. It is expected that these plans will mature during the year 1929 and that the necessary building operations will commence during the year 1930.

Uniforms for Meter Readers

A recent regulation of the Hackensack Water Co., Weehawken, N. J., provides that all employees whose duties require them to enter homes of consumers must wear uniforms, according to Nicholas S. Hill, Jr., president of the company. Inspectors, meter readers and collectors will be attired in dark gray whipcord with the initials "H. W. C.," in red, on the right breast, and will wear caps bearing the letters "H. W. C.," also in red. The purpose of the uniforms is to enable customers to identify water company employees, and to guard against unwarranted intrusion of homes by impostors who in the past have not infrequently posed as representatives of the company.

Athens Celebrates Opening of Marble-Faced Marathon Dam

The Marathon Dam, overlooking the immortal battlefield, where in 490 B. C., the Greeks overcame the conquering Persians, and built to provide the city of Athens with an adequate water supply, was officially opened Oct. 25, by the President of Greece, Paul Koundouriotis, according to dispatches received by Ulen & Co., New York City, the builders of the dam. Premier Venizelos and members of his cabinet, and other personages important in Greek governmental circles, as well as the foreign diplomatic body took part in the inaugural ceremony. A general holiday for Athens was declared.

Adequate water supply has always been a problem to the Greek capital, and as far back as 594 B. C. Solon enacted laws governing its consumption. Three years ago, Ulen & Co., signed a contract for the construction of the Marathon Dam and a new acqueduct tunnel 8½ miles through the base of Mt. Pentelikon, and together with the Bank of Athens formed the Societe Anonyme Hellenique des Eaux des Villes d'Athens, Piree et Environs to manage the water system of the city of Athens and Piraeus. The Marathon Dam is the first important step in this project. Through repairs and improvements of the old Hadrian Aqueduct, built 2,000 years ago, the city is now furnished with 14 gal. per capita daily instead of 3½ gal. per capita. During the year 1930 according to the engineers, the new aqueduct will raise the supply to 135 gal. per capita per day.

The dam itself is the gravity section arch type, faced up and down stream with the Pentelikon marble of which the classic structures on the Acropolis are built. It is filled with solid concrete. Measured along the crest, the dam is 935 ft. long, with a thickness at the base of 154 ft. and at the crest 15 ft. Its height above the stream bed is 177 ft. More than 40,000 tons of Portland cement and 10,000 tons of pozzulan cement were used. The reservoir formed by the dam will impound 10,825,000,000 gal. of water, and even if this supply was not added to, it would be sufficient for the needs of Athens for two years.

The water for the reservoir is drawn from the hills above the plains of Marathon and will be conveyed through the tunnel 8½ miles long and then through pressure pipes to the city proper. In order to relieve the meager supply the engineers have also constructed a salt water system which pumps water from the Aegean Sea for the sprinkling of the city streets.

Is the Boulder Dam Project on Colorado River Premature?

While there is little doubt that a large part of the Colorado River should be conveyed to Los Angeles County and neighboring territory eventually, we are by no means satisfied that work on this diversion should begin at once.

In 1924 the consulting engineers estimated that in 1950 the city of Los Angeles would have a population of 2,180,000, of whom 80 per cent would reside in 60,000 acres having at least 14 people per acre. They estimated that these 1,740,000 people (who will be designated hereinafter as urbanites) would use 130 gal. per capita per day for domestic purposes, plus about 32 gal. additional for industrial purposes. We deduce the 32 gal. from their estimate of 62,500 acre-feet of water annually used industrially in an area of 25,000 acres outside the 60,000 acres of urbanite territory, their estimate being 2.5 ft. of water per acre of industrial land. The combined domestic and industrial consumption of the 1,740,000 people in 1950 was estimated at 316,500 acre-feet, to which was added 248,000 acre-feet for the remaining 20 per cent of the population who will be designated here as "farmers." If the "farmers" used 130 gal. per capita per day for domestic purposes, that would take about 63,000 acre-feet, leaving 185,000 acre-feet for irrigation, or about one-third of the total 564,500 acre-feet used within the corporate limits of Los Angeles in 1950. For the farm districts the engineers estimated 2 ft. of water per acre per year.

Continuing the estimates of the consulting engineers, we have the following "Water requirements of the metropolitan area of Los Angeles County including city of Los Angeles in 1950."

	Acre-feet
Domestic use by "urbanites"	386,000
Industrial use	150,000
Domestic irrigation and other uses by others	823,000
	1,359,000

This last item is rather misleading, for by placing the word "domestic" first it produces the impression that "irrigation" is subordinate in importance, whereas as above shown, about 75 per cent of this item in Los Angeles city is for irrigation. If we take 75 per cent of 823,000 acre-feet as being for irrigation we have 627,000 acre-feet, which is nearly half the total estimated water consumption in Los Angeles county in 1950.

This immediately discloses that the proposed increase in water supply for the Los Angeles district is quite as much a farming project as a municipal project.

We believe that a similar analysis of the proposed uses of the Colorado River water elsewhere in Southern California will disclose that much more than half the water is intended to irrigation. While there is nothing wrong in such a plan, we doubt whether many of the city residents realize that they are being asked to vote bonds that are to be mainly used for developing farms.

Los Angeles county and nearby areas are already great agriculturally, and it may pay to develop them even more intensively, as producers of citrus fruits, grapes, etc. But judging by the wails that have repeatedly come from the growers of those products, overproduction has already made it difficult for them to reap a satisfactory profit. If with water lifts of only 100 ft., a farmer finds his profits small, what will they be when he has to pay for a 1,500-ft. lift over the divide between his farm and the Colorado River?

This is an economic question that we have never heard asked before, but it is certainly one to which both the rural and the urban residents of southern California are entitled to a definite answer.

In an article elsewhere in this issue data are given showing that at least 180 second-feet of additional water can be brought from the Mono Lake basin to Los Angeles. This would supply about 720,000 people with 160 gal. each per day. The cost of securing this additional supply is roughly estimated at $30,000,000.

We shall not be surprised if a study of the water resources of the Mono basin and the Walker River basin to the north of it, will show that 2,000,000 more people can be adequately and economically served from these regions of the eastern slope of the Sierra Nevadas, provided that the water is not used for irrigation but only for domestic and industrial purposes, and provided that none of it is wasted in developing water power at times when it should be stored for future domestic use.

Some years ago the editor appraised the hydroelectric power plants and water rights of the Southern Sierras Power Co. and subsidiaries in the Mono and Owens River regions, and thus gained considerable knowledge of the water resources of that region. He has visited that section many times in recent years. His belief is that the water resources of the Mono basin and the Walker River region to the north, may prove to be great enough to provide for the growth of metropolitan Los Angeles for another decade and still leave time in which to build the Colorado River aqueduct. All this provided that a great irrigational development of the Los Angeles district is not undertaken in the meantime.

As the article on the Mono basin project states, about $30,000,000 will be needed to acquire lands and water rights in that region, and to build reservoirs and aqueducts that will feed the Mono waters into the present Los Angeles aqueduct. While this is a large sum, it is dwarfed by the proposed Colorado River project. A vastly greater sum than $30,000,000 would be justified if the Colorado River project could be postponed 10 years.

The cost of the dam and power plant for that project is estimated at more than $150,000,000 and the aqueduct at about a like sum. Since great projects of this sort usually exceed the estimated cost, it would not be surprising were the entire project to cost $400,000,000 or more. It would seem needless to say that such an undertaking should not be lightly entered upon. Yet thus far it seems not to have had half the engineering study that it calls for, before even deciding to spend $300,000,000, to say nothing of deciding as to how long that construction can be wisely deferred.

We know that a great deal of important surveying and other engineering work has already been done, that many preliminary estimates have been made, and that the project is feasible. But what engineer is willing as yet to stake his reputation on what the project will cost?

In a recently published paper by Mr. R. H. Moulton, of Los Angeles, on "Financing Control of Water," we read: "Los Angeles and Southern California is again faced with a water crisis looking ten years ahead. The only conceivable plan existing at this time to adequately care for the future, will result in the building of the Boulder Canyon Dam by several states and subsidized by the Government, which will cost between $150,000,000 and $200,000,000. In addition to this, the aqueduct must be built several hundred miles, which will cost between $150,000,000 and $200,000,000."

What we wish here to emphasize is the indefiniteness of such cost figures. Between the $300,000,000 and the $400,000,000 there is a spread of $100,000,000, a difference sufficient to build a waterworks system to supply 1,250,000 people in the typical American city. We insist that where such vagueness exists as to the probable cost of a project, a great deal of engineering work remains to be done on it. But almost as important is the necessity of a most thorough study of other projects that may serve to postpone the enormous investment that the Colorado River project will involve.

If it be argued that at least half the investment will be self-supporting through the sale of industrial power, this too calls for careful study. To begin with there is a fair prospect that before the expiration of the bond amortization period of 50 years, there will be no power available except for pumping the water over the "divide." Little enough is known as to the probable rate of silting up of the proposed dam, but that little is ominous.

The Colorado River project is amazingly bold; unquestionably feasible and certain to be carried out eventually. But it is not like the purchasing of certain advertised goods whose makers' cry is, "Eventually—why not now?" To build this project now may be a great mistake, and we contend that until other projects are thoroughly examined it is likely to be a mistake.

We repeat a suggestion that we made several months ago: Many entirely separate groups of consulting engineers should be employed to study all the possible alternatives involved in this very complex problem. The fees of all of them combined will weigh as nothing when contrasted with the saving that some one of them is likely to effect. Parsimony in the hiring of consulting engineers may not account for the prospective abandonment of the San Gabriel dam site after spending $3,000,000 there; but it is fairly certain that had more consulting engineers been employed, some one of them would have pointed out the grave risk of running into unsuitable rock beneath the dam. Months before the rock slide at the dam occurred, M. M. O'Shaughnessy, City Engineer of San Francisco, said: "I understand lately the County Board of Supervisors of Los Angeles, in the plentitude of their political wisdom —after awarding a dam contract—dispensed with the Board of Consulting Engineers who had been employed on the San Gabriel Dam, a work involving an expenditure of $25,000,000. I believe this is a daring act of ignorance on their part, and a consulting board of wisdom and experience should be retained to supervise all features of the construction of this extraordinarily large project. In San Francisco we spent over a quarter of a million dollars hiring the best consultants in the United States to pass on the merits and features of our water project, and I believe it was the wisest money ever spent by the city."

If one board of three consultants was none too many on the San Gabriel Dam project, a dozen such boards would be no more than adequate for the Colorado River project and the other projects that may serve to postpone going to Colorado River. When we suggest several independent boards we have in mind the desirability of avoiding falling into ruts. Where a large number of men work on a board, usually a "we too" tendency develops, whereas what is really needed is more individualism. Moreover, competition among engineers, as among any other class of men, is the best of spurs.

The Rock-Fill Dam as a Safe Structure Where Bed Rock Is Faulted

After spending $3,000,000 in preliminary work and excavation, the proposed $25,000,000 dam in San Gabriel Canyon, near Los Angeles, will probably be abandoned. The faulted condition of the bed rock has become more evidently serious at greater depths.

The failure of the St. Francis dam, probably as a result of movement of the earth's crust along a fault beneath the dam, is still vivid in the memory of Californians. Hence the recent large slide of rock during the excavation of the San Gabriel dam foundation may spell abandonment of that dam site. Yet we raise the question whether this very favorable site should be abandoned. While we doubt the wisdom of building a concrete dam at that site, we believe that a great rock-fill dam could be safely built there.

As many of our readers know, the rock-fill type of dam consists of uncemented rocks sheeted on the upstream face with an impervious sheet of wood or metal. It resembles an earth dam in its massiveness, but differs in being permeable to any water that leaks through the sheeting. Consisting mainly of large stones, leakage streams do not cut the dam away as would occur if it were made of earth. Indeed, its very porosity is a safeguard, for no water can accumulate in its interior.

In a site where faulted rock exists, the rock-fill dam is unquestionably the safest type, if there is any likelihood that a slip may occur along the fault line. In a district subject to slight crustal movements, no fault should be regarded as a "dead fault." Geology is not yet such an exact science that a distinction can be drawn between "live faults" and "dead faults," other than one as to frequency of movement. Given a sufficient period of time, and it is probable that every "dead fault" will come to "life" again, just as many an "extinct" volcano has suddenly ceased being extinct.

The editor has found that there are 12 molton whirl centers in the earth, and that they are still active. Since these molten whirls are caused by the same electromagnetic forces that cause cyclonic storms, earthquakes are most frequent when great storms are most frequent. There is one great sunspot, storm and earthquake cycle about 81 years between "peaks," the last peak being about 1870. There is another similar cycle of about 161 years, its last peak being in 1778. There is another cycle of about 322 years, its last peak being in 1675. Halfway between these peaks, and often at intervals of one-sixth the length of these cycles, great weather and crustal disturbances occur. And the same holds true of the 11.2-year cycle, whose last peak was about a year ago, and whose weather and earthquake effects have been so pronounced at intervals during the past 18 months.

About 1939 and 1951 great crustal disturbances will occur, for those are the peak years of the 81 and the 161-year cycles. A fault that has been "dead" since 1871 may suddenly become alive in 1939 or sooner. So the geologist who bases his decision as to "deadness" of a fault upon evidence less than half a century old risks not only his reputation but the lives of all who live within the flood flow from a bursted masonry dam built over a "dead fault."

The only types of dam that have yet been built that invariably have resisted such crustal movements are those of earth or of loose rock. We have yet to hear of a dam of those types that has been destroyed by a crustal slip. Whereas, for reasons given at length in our issue of May, 1928, the St. Francis dam undoubtedly was destroyed by a slight movement of the rock beneath it along the line of an old fault. Other mysterious failures of masonry dams may have had similar causes.

California is the original home of the rock-fill dam, we believe. At any rate, there are many such dams in that state, and few in other states. Originally designed as an economic way of impounding water for placer mining use, it soon came into use for irrigation reservoirs. Later it was used by hydroelectric power companies, notably the Southern Sierras Power Co. and the Nevada-California Power Co., whose dams were studied by the editor a few years ago during an appraisal that he was making of the properties.

To the engineers of California we recommend a careful study of all the rock-fill dams in that state, with a view to using that type of dam wherever an otherwise good dam site is marred by faults in the bed rock.

Announcement of Articles on the Electron Theory of Weather and Allied Phenomena

In October a series of articles on the electron-whirl theory started with one on "Five Important Weather and Earthquake Cycles" in Water Works and Sewerage, and one on "The Periodicity of Geological Epochs" in Engineering and Contracting. This series will contain 16 or more articles based on the same theory, the articles relating to rainfall and air currents appearing in Water Works and Sewerage, while those relating to the geological and astronomical phases of the electron-whirl theory will appear in Engineering and Contracting.

The researches on which these articles are based have taken nearly all of the writer's time during the past three years. Starting as an inquiry into the relationship between sunspots and weather, the study broadened when it was found that in the neighborhood of certain centers of permanent cyclonic air whirls there is clear evidence of permanent whirls of the molten matter beneath the earth's crust. Later it became evident that the vagaries of the magnetic needle are largely accounted for by these same molten whirls, even to the slow oscillation of the magnetic poles. Since the molten whirls obviously affected topography, it became necessary to study the location of mountain chains and islands and the shapes of continents, in relation to these whirls; and from this gradually emerged the conception that 12 great molten whirls have been the main architects of the earth's crust. Never was the unity of nature better illustrated than in the correlation of phenomena seemingly so different as are sunspots, earthquakes, storms, and terrestrial lines of magnetic force. Aurora and magnetic storms had been previously correlated with sunspots, and one astronomer, Jerome Ricard, had been using sunspots as a means of predicting rainfall. Huntington had found a relation between barometric pressure and sunspots. Douglass had shown that radial tree growth often discloses an eleven year cycle corresponding to a well known sunspot cycle. De Geer had found the same cycle in the varying thickness of the annual sedimentary laminae ("varves") in ancient glacial lakes. Indeed, no small array of facts relating to the weather periodicity were available; but they were bound together by no definite theory susceptible of proof by an appeal to the laws of probabilities. Astronomers were in doubt as to the cause of sunspots. Meteorologists were in no doubt as to the cause of cyclonic storms, but unfortunately they were wrong, for their theory was in conflict with many facts. Geologists were in disagreement as to the cause of crustal movements and were not disposed to see much significance in facts that pointed toward their periodicity. Physicists had given but little thought to the electron as a cosmic force, and almost no thought to it as a force capable of causing weather changes. In general, astronomers ignored weather, weather men ignored astronomy, and physicists almost ignored both of those fields as realms of electron activity.

Under these conditions, it seemed to the writer that an engineer might be capable of coordinating facts and theories in these three realms of science; for since engineering consists in applying science, an engineer is not only capable of understanding any science, but of drawing sound inferences from scientific data.

Engineering is such a cosmopolitan profession that its followers are engaged in every sort of scientific work, from astronomy to farming, from the most purely "pure" to the most purely practical use of organized knowledge.

We take this occasion again to urge upon engineers the cultivation of a greater confidence in their ability to fathom nature's mysteries, regardless of the artificial realms in which scientists locate them. Nature is not a congeries of entirely independent classes of energy, but is a vast array of phenomena that are closely kin and probably identical as to the ultimate units whose varied motions and groupings produce this infinite variety that we call the universe.

Sewage Disposal at Amarillo, Texas

General Features of New Plant, Including Preliminary Settling Basins, Aerating Tanks and Sludge Lagoons

By WYNKOOP KIERSTED
Consulting Engineer, Kansas City, Mo.

AMARILLO is located on the High Plains in the Panhandle of Texas at an elevation of about 3,600 ft. above Gulf level on a divide between the South Canadian River and the Pala Duro Creek, a branch of the Brazos River. The ground slopes moderately south and southeastward and rather rapidly north and northeastward into the valley of the South Canadian. For a long time the city was a distributing center of a stock raising country under moderate agricultural development. Its public utilities had kept pace with its growth and were ample for its use until the intensive development of the gas and oil field commenced about 60 miles northeast of the city. The vastness of the oil and gas bearing territory and its great possibilities advertised Amarillo extensively and it became a center for oil and land speculation. A large amount of capital went into oil and gas development, new additions were laid out in the city, and the rapid growth of commercial and industrial enterprises resulted in much building activity and a correspondingly great growth of population. Within a period of two years the population of Amarillo nearly trebled and is now estimated at 45,000 to 50,000 inhabitants. The demand for the extension of the public utilities became correspondingly urgent and even the private utility companies had some difficulty in keeping pace with the demand.

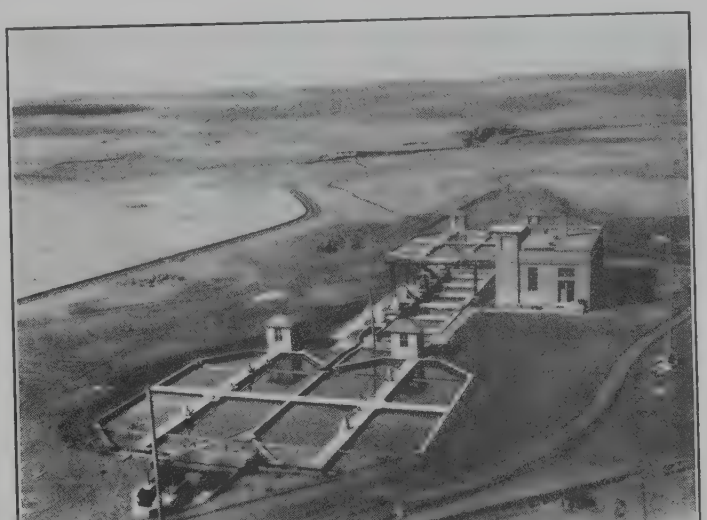

Fig. 1—General View of Settling Basins, Aeration Tank and Blower House

The Old Disposal Plan.—There are no perennial streams in the vicinity of Amarillo, consequently the city had constructed Imhoff tanks for the disposal of its sewage, discharging into one or more irrigating ditches which distributed the sewage over an area of about 120 acres, which was the only portion of the city owned section of land susceptible of irrigation. The land was cropped but the area was too small for successful broad irrigation and considerable offense arose as the result of overtaxed ground. This condition, together with the usual troubles with Imhoff tanks grew steadily worse until the commission, pressed for a remedy for offensive odors, constructed an outfall sewer from the Imhoff tanks 4 miles to a discharge into East Amarillo Creek.

The bed of this creek is dry for the greater portion of each year except for an occasional pool of water sustained by trickling springs and has an average fall of a little over 27 ft. to the mile for approximately 17 miles to its junction with the South Canadian. The constant flow of raw sewage in this ephemeral stream caused nuisances and completely destroyed the value of its water for stock raising purposes, one of the chief industries in that section of the country. With the rapid increase of population these conditions became intolerable and finally the city determined to extend and improve its sewage disposal plant.

Preliminary Investigation and Report.—The author of this paper in making an investigation and report on the situation found that land values were rapidly increasing and that urban growth was continually progressing towards the city owned section of ground on which its disposal plant was located and in fact had passed this section along the adjoining Colorado-to-Gulf Highway. For this and other reasons a new disposal plant was advocated on a site in the valley of East Amarillo Creek four miles below the end of the city outfall sewer. The site selected was particularly advantageous because it is two miles from the nearest residence and the public highway and because here there is a tract of 400 to 600 acres of gently sloping ground in the valley of East Amarillo Creek which could readily be brought under irrigation—a very desirable consideration in an irrigating country.

The author recommended the removal of 80 per cent of suspended matter of the sewage in settling basins and the application of the effluent from the settling basins to land in broad irrigation during the growing season and the chlorination of the effluent from the settling basins and discharge into East Amarillo Creek during the non growing season. The city commissioners demurred on obligating the city to the operation of a large sewage irrigated farm as a municipal enterprise but were willing to turn the sewage over to the owner of the property for use in irrigation as a private enterprise. In the end the commission requested the engineer to prepare plans for a trickling filter to receive the settled sewage

with a provision in the specification to receive bids on the trickling filters independently. The author also recommended sludge disposal in lagoons, both because of the isolation of the site and because the available funds were insufficient for the construction of separate concrete digestion tanks.

The lowest bid on the four miles of 18 in. outfall sewer was $52,489, that on the settling basins and lagoons $121,000 and that on about an acre of trickling filter $124,900. The bids on the filter

Fig. 2—View of Disposal Works and Lagoons

were finally rejected because of insufficient funds, but contracts were awarded for the outfall sewer and settling basins. The former was completed in the early fall and the latter in the late fall of 1928. A general view of the settling basins, aerating tank and power house is shown on Fig. 1. Figure 2 shows a partial view of the structures and the earth lagoons. A space of ground is reserved between the structures and the lagoons for the construction of trickling filters at some future time. In the foreground of Fig. 1 is the two-compartment screen chamber equipped with inclined bar screens, the necessary valves and an overflow well between the two compartments. The screen chamber connects with the preliminary settling basin by concrete conduit.

The Preliminary Settling Basin.—The preliminary settling basin in the foreground is composed of two compartments, each compartment having two cone-shaped hoppers provided with a vertical rotating shaft with two horizontal arms to which is attached a chain drag. The two compartments are, as a rule, operated in parallel but either may be emptied and the sewage diverted into the other by means of stop planks. The sewage enters each compartment on the longitudinal center line and is given a straight line flow through the basin by means of a suspended wooden baffle with vertical slots the entire depth of the baffle ⅝ in. wide and 6 in. apart. These baffles extend nearly to the bottom of the basins. The sewage is removed by a double-lip weir extending across each compartment of the basin in the position shown in Fig. 1. The position of the weir tends to prevent currents up the wall. The two little structures at the end of the settling basin (see Fig. 1) house the motor and reduction gear which communicates with the line shaft running along the center line of each compartment and which rotates the chain drags. The speed of operation of the vertical shaft is 3 revolutions per hour. The object of using chain drags is to prevent adhesion of the settled solids to the concrete bottom of the hoppers. The sludge is drawn hydraulically through a compound plug valve in each of the hoppers. The larger opening of each plug valve is 12 in. diameter and the small one 3 in. diameter. The 3 in. valve is intended to be partially open all of the time or opened periodically. The 12 in. valve is opened only when desired to drain the basin. The detention period in the preliminary basin is 2 hours at an average rate of sewage flow of 3 m.g.d.

The Aerating Tank.—The sewage from the preliminary basin passes through a flume into an aerating tank 95 ft. long, 19¾ ft. wide and 10 and 20 ft. deep and is given straight line flow by means of a suspended baffle extending nearly to the bottom of the tank with ¾ in. vertical openings spaced 6 in. apart. The aerating tank contains six steeply sloped hoppers 10 ft. deep with a plug valve in the bottom of each hopper connecting with a drain constructed beneath the floor lengthwise of the tank. A 12 in. air-lift pump is installed in each of the six hoppers. Each pump has a capacity to lift 1,240 g.p.m. 4 ft. with air of 3 lb. pressure. The pumps discharge the sewage into a concrete trough constructed on the top of the aerating tank and shown on the left side of the tank in Fig. 1. The sewage thus pumped into the tank flows back to the inlet. The six pumps operating continuously deliver sewage into the trough at the rate of a little over 10½ m.g.d. Thus the sewage is withdrawn from the tank, aerated and returned to the inlet and nearly four times during the one hour detention period when the flow from the preliminary basin is at a rate of 3 m.g.d. The purpose of the aeration is to remove the gases from the sewage and to break up insofar as possible the colloidal condition of the suspended sediment. Little oxidation of dissolved organic matter is expected. The sewage is weired into a trough at the outlet end of the tank, thence passing into the secondary settling basin which is structurally a duplicate of the preliminary basin. Thus the sewage is detained in the settling basins and aerating tank 5 hours at the stated normal rate of flow.

The Sludge Lagoons.—The sludge lagoons, covering an area of between 3 and 4 acres, were constructed of earth embankments in three divisions of approximately equal capacity of an average depth of about 11 ft. It was designed to use one at a time until fully charged with sludge, then deliver the sludge to the second lagoon while that in the first was digesting and so on until the use of the third became necessary when the sludge in the first should be in a condition for removal. The overflow from the lagoons passes onto a 5-acre leveled area inclosed by a low embankment where it is expected to disappear by evaporation and by seepage through the ground into the adjoining stream. Since the evaporation in the Panhandle district of Texas approximates 5 ft. per year, no difficulty is expected in disposing of this overflow by evaporation. Some odor is expected from the lagoons, but because of their isolation and the prevailing southerly winds no offense is expected to dwellers along the highway two miles to the westward.

The Blower Units.—The building adjacent to the aerating tank contains three Connersville blowers, each unit having a capacity to compress 700 cu. ft. of free air per minute to a pressure of 3 pounds and to deliver it to the air-lift pumps. These motor driven blowers of the rotary displacement type operate at 575 r.p.m. The air for the blowers enters the tower at one corner of the building, passes downward through air filters, thence into a duct beneath the floor of the blower room to the blowers and is delivered to the pumps through a 12 in. pipe line. In the building are also installed a Wallace & Tiernan chlorinator and a dry feed machine for feeding either alum or copperas either where the sewage passes into the aerat-

ing tank or into the secondary settling basin.

The plant has now been in operation about a year. An average of two weeks', analyses of the sewage passing through the outfall sewer prior to the construction of the new sewage disposal works, showed the dissolved and suspended solids to be 1,570 p.p.m., dissolved solids 1,120 p.p.m., suspended solids 450 p.p.m., hydrogen-ion concentration 6.8. The total dissolved solids in the city water supply was 363 p.p.m. This unusually strong sewage for a city like Amarillo is due in part at least to the absence of ground water infiltration and to the scarcity of city public water supply at the time the tests were made. Provision was made for prechlorination of the sewage at the head of the outfall sewer near the city limits in order to delay septic action at any time the sewage was found to be septic as it entered the disposal works. So far as we know there has been no occasion to prechlorinate because the time of passage through the 8 miles of outfall sewer, half of which is laid at an average gradient of .66 per cent and the other half at an average gradient of .25 per cent, has not been long enough to start any pronounced septic action.

Operating Results.—During the time the disposal plant was under construction about a mile of irrigation ditch was constructed; the owner of the adjacent property, extending for miles in every direction, having arranged to irrigate some at least of his land susceptible of irrigation. After the disposal plant had been in operation several weeks an efficiency test was made of it in December, 1928. For the first five days of this test the sewage passed through the old Imhoff tanks near the city limits. It entered these tanks with 520 p.p.m. of suspended matter but the effluent still contained 205 p.p.m. This effluent then was passed through the new disposal works where the suspended matter was reduced from 205 p.p.m. to 45.5 p.p.m., which represents nearly 78 per cent removal of the suspended solids in the Imhoff tank effluent. The Imhoff tanks were then cut out and the raw sewage, still containing 520 p.p.m., was passed directly through the new disposal plant in which the suspended solids were reduced to 30 p.p.m., representing an average removal during the five days' time of the test of 94.2 per cent of suspended solids. The average condition of the effluent from the preliminary basin during the test was 60 p.p.m. of suspended matter, or about 88.46 per cent removal. The remaining 30 p.p.m. removed in the secondary settling basin after aeration is equal to 50 per cent of removal of the remnant from the preliminary basin or little over 5.7 per cent of the total suspended solids. No records of summer time operation are now available. The records further show an average removal of suspended matter up to Feb. 5, 1929, of a little over 89 per cent and a reduction of the biological oxygen demand of 63.7 per cent on the basis of the 5-day test.

The plant is capable of removing at least 90 per cent of the suspended matter under careful supervision. We are informed that the city commission entered into contract with the owner of the property adjoining and including East Amarillo Creek to remove 90 per cent of the suspended matter in the sewage delivered to the disposal works. With this 90 per cent removal the sewage is in excellent condition to be applied to land in broad irrigation without becoming offensive and in the same condition it is thought it could be applied to a trickling filter with 6 ft. depth of stone of about half the area generally allowed for the purification of the effluent from Imhoff tanks. This distinctly represents a probable economy of the usual plant investment since a filter is more expensive than a settling basin.

Contract for Well Drilling

Well drilling involves many uncertainties, and even without a guaranty as to water the driller assumes much financial hazard. A form of contract that gives a driller an adequate reward for skillful performance without requiring him to assume undue hazards is given by Oscar E. Meinzer in U. S. Geological Survey Water Supply Paper 597-C, "Problems of the Soft-Water Supply of the Dakota Sandstone." We quote as follows:

If the water is obtained from hard rocks, the driller may have performed his entire duty when he has sunk the hole to the required depth. If, however, the water occurs in beds of sand or other incoherent material the driller's work is not complete when he has made the hole, but only when he has, so far as possible, developed or finished the well in such a manner that it will yield a water supply without inflow of sand, silt, or clay and will remain in good condition for a period of years. The process of developing or finishing the well requires quite as much skill as the process of making the hole, and, if properly done, it may consume much time. A reliable driller will not leave a well in an unfinished condition or in a condition that will cause trouble in the future. However, if he is paid only at a certain rate per foot for making the hole, he can hardly afford to spend much time in developing the well, and if he does so he is at a great disadvantage with his less scrupulous competitors. In localities where wells end in sand it is therefore desirable to devise a form of contract that will give the driller adequate reward for skillful work in finishing a well without requiring him to assume undue hazards. Such a form of contract will also be advantageous to the persons for whom the wells are drilled, for it will tend to give them the services of skillful drillers on competitive terms.

The problem of a proper form of contract confronted the United States Office of Indian Affairs when it asked for bids for drilling the well at the asylum at Canton. The following specifications are essentially as they were prepared by the Geological Survey with a view to meeting the conditions outlined above:

Specifications for one well to be sunk at the Asylum for Insane Indians, Canton, S. D., into the sandrock that bears soft water:

The bidder shall furnish all equipment and labor necessary properly to construct and finish the well and shall furnish the casing and strainer and any other material or element that may be required to construct the well in a workmanlike manner. He shall case the well from top to bottom with 8-in. standard casting or pipe. [Diameter was later specified to be 6 in.] He shall so construct the well at the bottom as to shut off and seal the well from any water entering from above the soft-water sandrock. He shall also construct the well in the soft-water sandrock at the bottom in such a manner that it will furnish at least 15,000 gal. of water in 24 hours without interference or trouble from sand or any other cause during a pumping test of at least two days' duration. He shall commence sinking the well within a reasonable period after the approval of his contract, shall continue operations without any unnecessary delay until the well is finished, and shall complete the well by Nov. 1, 1926. When the well is completed with the above-mentioned guaranty as to yield and freedom from interference by sand or from other trouble, he shall receive full payment at the rate of $—— per foot of well drilled.

It is understood that the well shall be drilled to a maximum depth of 350 ft., if necessary, unless the hard Sioux quartzite, or "Sioux Falls granite," is struck before that depth is reached. It is further understood that in case it is impossible, on account of the absence or unsatisfactory character of the sandrock, to fulfill the above-mentioned guaranty, the contractor shall be paid at the rate of one-half of the above-mentioned price per foot drilled.

Because of the guaranty of "15,000 gal. in 24 hours without interference or trouble from sand or any other cause during a pumping test of at least two days' duration," the contract was attractive only to skillful drillers, and it gave the successful bidder a strong inducement and a proper reward for doing his best work. On the other hand, by specifying half price if the driller should not succeed in fulfilling the guaranty, he was protected from assuming an excessive hazard. In general, government contracts for drilling wells have been very exacting in their requirements, and this has resulted in discouraging bidders and in making the bids excessively high. It is believed that an equitable and reasonable contract is to the interest of the government in procuring the services of skillful and reliable drillers at moderate prices.

The advantages of this form of contract could, of course, have been obtained with specifications of other kinds. For example, the driller might be paid a certain price per foot for making the hole and an additional sum for fulfilling the guaranty. This would not be very different in effect from the actual specifications but would have the disadvantage of requiring a more complicated bid and of being a more radical departure in form from the usual contracts.

The successful bidder for the contract for the asylum well was Mr. E. C. Archibald, Council Bluffs, Ia., whose bid of $5 a foot was the lowest submitted.

Developments in 1929 in the Chemical Treatment and Filtration of Water

Taste Elimination—Prevention of Corrosion—Water Softening—New Filtration Plants—Coagulation —Laboratory Work—Bacterial Quality—Design and Equipment—Filter Clogging —The Surface Wash—Aeration and Chlorination

By JOHN R. BAYLIS
Associate Editor, Water Works and Sewerage

THE articles on water purification which have appeared in the various publications within the past 12 months indicate we are moving forward in this field at a very rapid rate. They cover practically every phase of water treatment, and it is evident that our scientists in the water purification field are keeping pace with those in other lines of work. Certainly there is no period in history in which the work has been on so high a plane or the achievements greater. The American Water Works Association with its water purification division and 17 local sections, the New England Water Works Association, the American Chemical Society, the American Society of Civil Engineers, the various state organizations which hold annual meetings, such as water works schools and conferences, and other technical societies, all have programs at their various meetings with one to a number of papers on water treatment and filtration. In addition to the proceedings and journals of these organizations, there are several other publications giving a great deal of space to water purification. Surely such an abundance of literature records much that represents improvement in the treatment of our drinking water. Also it is creating an interest in the subject far greater than our expectation of only a decade ago.

It is not one or two achievements that makes the past year noteworthy in accomplishments, but improvements along many lines. The young and the old, the newcomer and the veteran in water purification have put their shoulders to the wheel and we are moving forward in a manner that makes us feel proud. The most difficult problems are being attacked by men well trained in their work, and some of the problems that have baffled us heretofore are being solved. Each year brings about a greater sense of responsibility on the part of the chemist and the engineer to produce safer and more palatable water.

Water Borne Diseases Have Been Reduced to a Minimum.—The death rate of water borne diseases is diminishing almost to the vanishing point. Seventy-four cities with a population of 26,737,000 people reported 1,796 deaths from typhoid fever in 1918. These same cities with a population of 33,116,000 in 1928, reported only 627 deaths from the same cause. This is a reduction from 6.72 per 100,000 in 1918 to 1.89 in 1928, or over 70 per cent. We should like to think that only a few of the cases of typhoid fever in 1918 were contracted from water, for most of the plants had very good treatment for the removal of bacteria at that time. The record indicates, however, that there has been no let-up in the efforts to have the water entirely free from disease producing bacteria, even though some of the supplies before treatment have become more highly polluted. Before a supply becomes contaminated to the point where there is doubt as to the safety of the water, and a less polluted supply is not available at a reasonable cost, improvements are made in the methods of treatment so as to take care of the increased pollution.

Taste Elimination.—More and more do we realize that the public wants water of the highest quality and water free from objectionable tastes. Perhaps the greatest achievement in the water purification field for some time has been the perfection of treatments to remove or to prevent objectionable tastes. This, of course, is not a development originating within the past 12 months, but much has been contributed to our knowledge of taste elimination during that time. Many water supplies at times are subject to disagreeable tastes that cannot be removed by coagulation and filtration. In some instances filtration has been discredited in the eyes of the public because perfectly palatable water is not being supplied all the time.

Efforts in taste elimination have been along several lines. Probably the most notable contribution to taste elimination within the past few years has been made by Howard at Toronto. An excess of chlorine is added, and the water is later dechlorinated with sulfur dioxide. McAmis at Greeneville, Tenn., was the first to use ammonia in this country on a plant scale for taste elimination. Spalding at Springfield, Ill., and Ellms at Cleveland, O., report good results with ammonia. Potassium permanganate is being added to several water supplies with apparently very good results. Caird at Rochester, N. Y., was the first to use this material on a plant scale. Harrison at Bay City, Mich., finds potassium permanganate effective in preventing tastes, but does not get very good results with ammonia. Recently it has been found that activated carbon is very effective in removing taste-producing compounds from water.

Ammonia apparently prevents the formation of the chloro compounds that produce disagreeable tastes. Potassium permanganate and superchlorination oxidize certain of the taste-producing compounds, whereas activated carbon absorbs the compounds. With a combination of superchlorination and activated carbon, which also dechlorinates the water, practically all objectionable tastes that are likely to occur in a water supply may be removed. Superchlorination, preammoniation, and the use of potassium permanganate have the advantage that very little plant investment is necessary, but such treatments require close supervision. Reports from various points where these treatments have been tried indicate they are not successful in the complete elimination of all tastes, but certainly they can produce a marked improvement in the taste of the water in many localities.

No one so far has reported a taste that cannot be removed by superchlorination and then passing the water through a bed of active carbon. The use of the active carbon also obviates the necessity for close chlorine control. Such excellent results should insure extensive use of this process. Due to the fact that the carbon is expensive, and that provision has to be made for passing the water through a bed of the material, the initial cost is high. The operating cost is low, and when every thing is taken into consideration the cost compares very favorably with other treatments. The fact that this treatment covers a wider range of taste-producing compounds that may be removed from water than any other treatment, and is almost fool-proof in operation, should make it particularly attractive to small cities.

If progress in water purification had been confined to taste elimination, the past year would still be noteworthy for its accomplishments. It has been demonstrated conclusively that the more common taste-producing compounds, such as are produced by decaying vegetation, micro-organisms and phenols,

may be completely removed by one or more of the several methods mentioned. No city willing to make the small expenditure need now tolerate disagreeable tastes, except perhaps in very unusual cases. It appears that most any water may be made perfectly palatable all the time for an expenditure less than $1.50 per million gallons.

Prevention of Corrosion.—Treatment of water to prevent corrosion and red water is being extended gradually to the corrosive waters. It has been about 10 years since the treatment was started at Baltimore, and every year sees a few more cities added to the list of those treating water to reduce corrosion. If the writer is correctly informed, New York City has abandoned its work on corrosion prevention for the present. This, however, will not discourage others who are anxious to deliver water to the consumer of the highest quality. In fact lime was not tried in New York on a large scale, and those who are familiar with corrosion prevention would not expect the sodium compounds to be of much aid on so soft a water. The advantages and economy of non-corrosive water are demonstrated quite conclusively in practically all places where it is given a fair trial, and it is likely only a matter of time until nearly all corrosive waters will be treated. Where various treatments for corrosion prevention, such as lime, soda ash, sodium hydroxide and sodium silicate, have been compared on a plant scale, lime shows its superiority over other treatments for very soft waters. For moderately hard to hard waters it probably makes little difference which material is used, except that lime is cheaper.

Water Softening.—More water softening plants are being constructed every year, and some of the existing plants are making their treatment processes still more effective. Where magnesia is present in quantities greater than 10 to 15 parts per million of Mg there is an increased use of what is commonly called the excess lime treatment. Lime is added to the water to produce a pH of 10.5 to 10.8 so as to precipitate most of the magnesia as magnesium hydroxide. This treatment leaves the water with 25 to 50 parts per million of caustic alkalinity, composed largely of calcium hydroxide. The caustic alkalinity has to be converted to the carbonate by the addition of carbon dioxide.

The greatest precipitation of calcium carbonate that may be effected within the few hours it takes the water to pass the treatment plant occurs at a pH of 9.5 to 10.0. This is high enough to give the water a taste characteristic of lime softened water. The use of carbon dioxide in softening plants is becoming more extensive, and the writer is of the opinion that practically all municipal softening plants using lime or soda will eventually recarbonate the water. The water should be left just saturated with calcium carbonate, or with only 4 to 5 parts per million supersaturation. In softening processes where calcium carbonate is precipitated, considerable supersaturation of calcium carbonate has to be produced for precipitation to take place. Usually 20 to 40 parts per million supersaturation of this compound is left in the water and it will incrust the sand grains in the filter beds and all surfaces with which the water comes in contact unless the water is given additional treatment. The addition of carbon dioxide is being found to be the most desirable additional treatment.

Zeolite softening is being extended rapidly to industrial plants where it is economy to have very soft water. There are now four or five municipalities using zeolite softeners. For laundries and boiler plants it is becoming the custom to use zeolite softeners where the hardness is in excess of 20 to 30 parts per million.

Taste elimination, prevention of corrosion, and water softening, constitute efforts to take a water of inferior quality after filtration and produce water of the highest quality. Surely our dream of the perfect water for every city is much nearer a realization than was believed to be possible only a few years ago. In many instances the water has been changed so greatly in characteristics due to the treatment that it should be regarded more as a manufactured commodity than one of Nature's products.

New Construction.—Construction of new filtration plants has progressed at about the usual rate. Twenty or more new municipal plants have been put into operation within the past year, the new Howard Bend plant at St. Louis probably being the largest. This plant is probably the most elaborately equipped filtration plant ever constructed. The beautiful exteriors of the new plants at St. Louis and Baltimore, and the interiors of the newer plants at Cleveland, Washington and St. Louis, set a standard in construction that will be followed by many plants in the future. In fact the influence is already noted in the imposing structures recently built in some of the smaller cities. Beautiful structures may not be necessary for the production of high quality water, but they are in keeping with the present tendency to make every thing in connection with water supply attractive.

Coagulation.—There has been only one major development in the coagulation of water within the past two or three years. Mohlman and Palmer found that chlorine added to a solution of ferrous sulfate produces ferric sulfate and ferric chloride, and that these compounds will produce coagulation when the pH is very much lower than is essential for ferrous sulfate to produce coagulation. Their work was on sewage, but it did not take the water chemist long to start experimenting with chlorinated iron to see if it had possibilities in water treatment. Good precipitation has been found to take place between pH of 5.0 and 11.0, making its range very much broader than that of aluminum sulfate. The work of Hedgepeth at Elizabeth City, N. C., Decker and Menke at Chicasaw, Ala., and the writer at Chicago, indicates that chlorinated iron is a better coagulant than aluminum sulfate for many waters. Ferric chloride appears to be even more effective than chlorinated iron, but due to its price being considerably higher than that of ferrous sulfate the cost of coagulating water with this material appears to be higher. It seems probable that the ferric compounds will give aluminum sulfate serious competition and probably will result in lessening the cost of coagulating water. The past year has contributed much to our knowledge of the use of chlorinated ferrous sulfate in water treatment.

Laboratory Work.—The hydrogen-ion test is now fairly well understood by water chemists and many are making use of the test in their treatment process. A knowledge of the hydrogen-ion concentration of the water is almost an essential for the most efficient application of chemicals to water, except where very small quantities of aluminum sulfate are added to hard or moderately hard waters.

The use of instruments to measure the turbidity of filtered water is being extended rapidly. The best operated filtration plants are striving to produce filtered water with turbidity not greater than 0.2. In fact we see several other pieces of new equipment in the leading water laboratories in addition to the sensitive turbidimeter, such as laboratory filters, stirring machines, and other experimental apparatus. More attention is being given to the laboratory in new filtration plant designs than heretofore. The new laboratory in the Howard Bend plant at St. Louis, perhaps the most complete of any filtration plant laboratory in the world, makes us feel that the value of the technical workers in such plants has not been underestimated by the designer.

Bacterial Quality.—The present bacterial standard allows an average of not more than 1 B. coli per 100 cc. of water. The better operated plants have set their aim much higher, and many plants are averaging not more than 1 B. coli per 1,000 cc. Until this latter figure is attained, the filter operator is not justified in reducing the treatment to save operating costs. In fact we may look for 1 B. coli per 1,000 cc. being the standard some day. The chemical advantage of superchlorinating polluted water is becoming so apparent that it will be this and not bacteria that will determine the amount of chlorine to be used in many plants. With a residual chlorine requirement of from 0.3 to 0.5 parts per million two or three hours after application, the

bacterial test becomes almost useless. The quality is insured by the residual chlorine test, and the safety of the water is known immediately and not several days afterward, as is the case when we have to wait for the bacterial results.

Design and Equipment.—In plant design and equipment there have been no recent developments of major importance. Most of the new plants are installing dry feed machines for applying the chemicals to the water, but this is more a matter of choice than any superiority of one method of applying chemicals over another. Better means of handling and storing chemicals are being provided. Air conveyors appear to be on the increase for transporting chemicals in the larger plants. Softening plants and other plants handling highly turbid waters are making greater use of continuous sludge removing devices in the settling basins. The value of a fairly long mixing period has been demonstrated in most waters, and most of the newer plants are being equipped with mixing basins having ample mixing time. Mechanical mixing appears to be on the increase.

There has been no radical change in the design of filter beds. Some of the newer designs have the sand beds located lower so that there will be little or no negative head on the beds. This lessens air-binding troubles. Twenty-four to 27 in. of sand is usually specified, and there is a tendency to use slightly coarser sand than a few years ago. It has been found that sand of 0.5 mm. to 0.6 mm. for the 10 per cent. size usually gives good filtration results and does not clog so quickly as finer sand. There still exists a variety of opinions as to the best type of underdrains for filter bottoms. With all the efforts that have been made to improve the filter bottom it is doubtful if anything so far tried has much superiority over perforated pipe laterals. The manufacturers of filter rate controllers and other devices for filtration plants have not come out with new models so frequently as manufacturers of automobiles and radios, but every year sees something new, or something that has been improved.

Solving Filter Clogging Troubles.—There has been a more determined effort to solve filter clogging troubles than heretofore. Hulbert and Herring at Detroit believe that a high rate of wash to give a sand expansion of nearly 50 per cent during washing will keep the beds in good condition. It is their opinion that an expansion of 40 to 45 per cent is the minimum for satisfactory results. It is hoped that so simple a treatment will produce the desired results, but the writer is of the opinion that it will not for many waters. It is true that many filter operators give very little attention to the wash rate actually being used, and it may be found that many plants are not using the 24-in. vertical rise for which the plant was designed, if a check-up were made. If sand expansion can be measured conveniently enough to insure its regular use, it will result in improved conditions at many plants. Is it not imposing a task on the operator that he very likely will not perform with a degree of regularity sufficient for good results? The writer is of the opinion that mechanical rakes or the surface wash is the only real solution to much of our filter clogging trouble. Mechanical rakes are not practical except in small circular filters, but the surface wash may be used on any size and shape bed.

The Surface Wash.—The surface wash is composed of pipe laterals located just above the sand surface and spaced about 18 to 24 in. apart with holes about 3/16 in. in diameter about 12 in. apart on both sides of the laterals. The holes are pointed downward at an angle of about 30 deg. to the horizontal. With a pressure of 20 to 30 lb. on the jets considerable agitation of the sand in the path of the jets is produced. The surface wash is used at the time the filter is washed from underneath. The force of the jets extends some distance from the pipes, but it is not great enough to disturb the gravel. Neither does it disturb the water above the suspended sand any more than it is disturbed by the usual wash. The force of the jets greatly agitates the sand and break up all mud balls and clogged masses of sand. The application of wash water underneath the bed to produce 18 to 20 in. vertical rise per minute and 4 to 6 in. through the surface wash gives an agitation of the sand much greater than can be produced by applying water underneath, regardless of how great the rise per minute may be. The success of the surface wash where it has been tried should insure its use in many filtration plants in the future.

Aeration.—A few of the recent filter plant installations provide for aeration. This is helpful in removing dissolved gases such as carbon dioxide, and in reducing certain of the taste and odor producing compounds. Aeration also is used for increasing the dissolved oxygen content of water low in dissolved oxygen. Recent developments in taste and odor removal indicate that aeration will not be extended very much for this purpose.

Chlorination.—Chlorine is being used in such a variety of ways in water treatment that no one can predict what the future will bring forth. The chief recent developments involving the use of chlorine other than for sterilization have been mentioned already. The addition of chlorine to the water in advance of filtration is on the increase, and the writer is of the opinion that prechlorination is an advantage for many waters.

It seems that one of the most important developments in water purification within the past 10 to 15 years is the type of men being attracted to this field. Ambitious, and well trained in the fundamentals of water treatment, we may expect much from such workers in the future.

Airplane Surveys Give Base for Plane-Table Work

In contributing to a discussion of the American Society of Civil Engineers on the application of airplane surveys to topographic mapping, W. N. Brown gave the following outline indicating the process followed:

"First, a controlled mosaic is made on plane-table sheets 24x30 in. in size. In order to get an accurate control mosaic, there must be located over the area a number of points that show on the photograph. Coordinate positions of these points must be computed and the points platted on the plane-table sheets. The photographs are then brought to proper scale in agreement with these platted points, and made into a photographic base map, upon which the coordinate lines are drawn. The plane-table sheet is then ready for the field where the contours are located by stadia vertical angle methods.

"The topographer, starting from a known control point, carries a continuous traverse for position and elevation, at the same time checking the accuracy of his photographic base map. This map also serves as a check against mis-read or mis-platted rods. If he reads a rod at a stream fork or fence line, or other definite feature, and it does not agree in position with that shown on the base map, he checks his reading and either discovers it to be his error or picks up an error in his base map. If the photographic base map has been properly controlled and made, the error will usually prove to be his own.

"The economy of field operation is apparent. He does not have to read rod for such details as stream and road location, buildings or other objects, but only takes rod readings necessary for controlling the contour location and checking the base map where he thinks it advisable. The field work is reduced at least 50 per cent. The resulting map has better expression of contours and details of stream than could be obtained for the same money by any other method.

"The error of scaling the distance between any two points located at widely separated distances on the map should not exceed 1 part in 5,000."

Water Purification in North Carolina.—One hundred per cent of the filtered surface supplies of North Carolina are chlorinated. Seventy-four of the 78 filtered supplies are scientifically operated, being either under chemical or chemical and bacteriological control.

Records and Tests for Sewage Treatment Plants

Methods for Determining Efficiency of Grit Chamber and of Solids Removal; Condition of Sludge, and Daily Flow of Sewage

By HERBERT BOSCH

Assistant Public Health Engineer, State Board of Health of Missouri

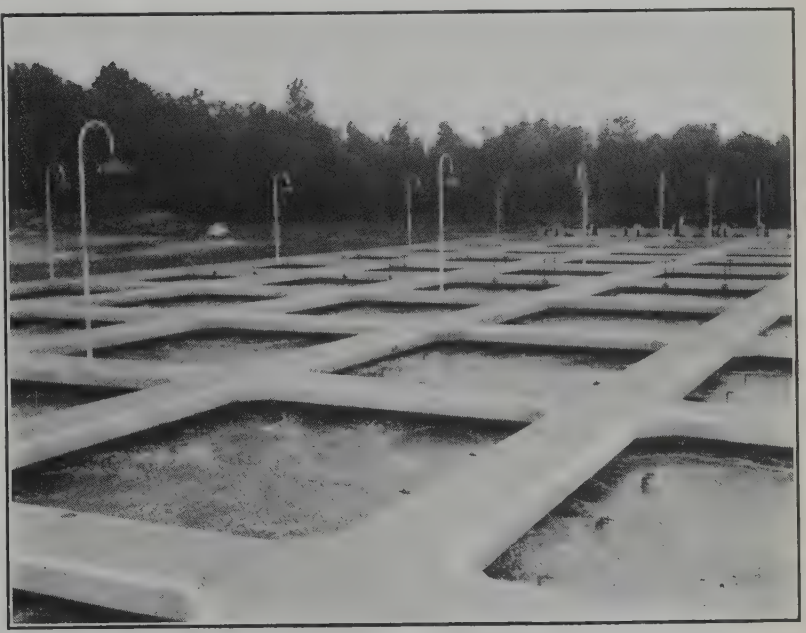
SEWAGE treatment plants are notably very far behind their companion municipal plants, the water works, in the matter of keeping of records and making of tests. The great improvement in the water works field, however, has not come about all at once but has rather been the result of years of constant work. It is not expected that sewage plants will change immediately from their present slipshod operation to a system of efficient control, but there should be at least a gradual trend in that direction. Much depends on the operator. Operation of a sewage treatment plant is a part of the municipal obligation, and the city must employ an operator who is capable of giving the plant intelligent operation.

Why Tests Should Be Made.—There are several reasons why simple tests should be made and records kept at sewage disposal plants. Needless to say, tests will give the operator an index of how efficiently his plant is operating. Despite a rather common opinion to the contrary, there is no type of sewage plant which will keep itself running effectively without attention. Routine tests give an advance warning of conditions which might impair the efficiency of a plant as well as evidence that the plant is running smoothly. Records of efficient operation are of value in court in event of suits against the city by landowners downstream from the plant for damages alleged to have been done by sewage in the stream. It is hardly necessary to point out that such suits are likely to occur at any time.

A second reason for making of tests and keeping of records lies in the fact that almost every town now having a sewage plant will sooner or later have to either extend or rebuild its present treatment plant. At such a time records of plant performance, and of the characteristics of the local sewage will be of inestimable value in making the addition to the old plant or in designing a new plant. There are very little data available now on the properties of sewage in this state and on the operating characteristics of various types of plants, and a designing engineer must depend on data from other localities where the conditions are not the same as they are in this state.

The first simple test which should be made is the temperature of the raw sewage, of the sludge and of the air. Temperature has a great influence on the digestion period necessary. Imhoff states that it takes twice as long to digest sludge at 50° F. as it does at 60° F.

Determining Efficiency of Grit Chamber.—Most plants, especially those which have combined sewers, are equipped with grit chambers, which should be designed to separate the inorganic solids from the influent sewage, but should not trap organic matter. To determine the efficiency of the grit chamber a sample of the grit is dried and weighed and then the volatile organic matter is burned off. The loss in weight represents the volatile organic matter. If it is high, say over 50 per cent, the grit chamber is removing too much organic matter, which tends to become septic and produce objectionable odors.



Aeration Tanks at Sugar Creek Sewage Disposal Plant, Charlotte, N. C.

How to Determine Efficiency of Solid Removal.—Most of the sewage treatment plants in this state utilize Imhoff tanks, but there are also a few separate sludge digestion plants in operation. In either one of these types of plants, some knowledge should be had of how efficiently the settling tanks are removing solids from the sewage. The simplest method of doing this is by means of Imhoff cones. These are glass cones about 15 in. high which are calibrated to hold one liter and are graduated at the tip. A liter of sample is placed in the cone and allowed to settle for two hours. At that time the solids which have settled in the tip of the cone are read off, the results being expressed in cubic centimeters per liter. If this test is made on the raw and settled sewage, the percentage of solids removed is very readily calculated. The only precaution necessary in making this test is to tap the cones gently after about 15 minutes of settling in order to insure that the solids do not adhere to the sides.

In activated sludge plants where sludge is being constantly returned to the primary settling tank, settleable solids are best determined by means of a cylinder rather than a cone. The contents of the cylinder are allowed to stand for one hour, after which it is read, the results again being expressed in cubic centimeters per liter.

If an analytical balance is available, the suspended matter by weight should be determined by the Gooch Crucible method. A Gooch crucible is a crucible provided with a perforated bottom which is covered with a thin asbestos mat. By the aid of suction, a definite volume of sewage is filtered through the crucible after which the crucible is

dried and the increase in weight is noted. From this the suspended matter in parts per million is easily calculated. The per cent removal of solids in the settling tank may be computed if this test is made on the sewage influent and effluent to the tank.

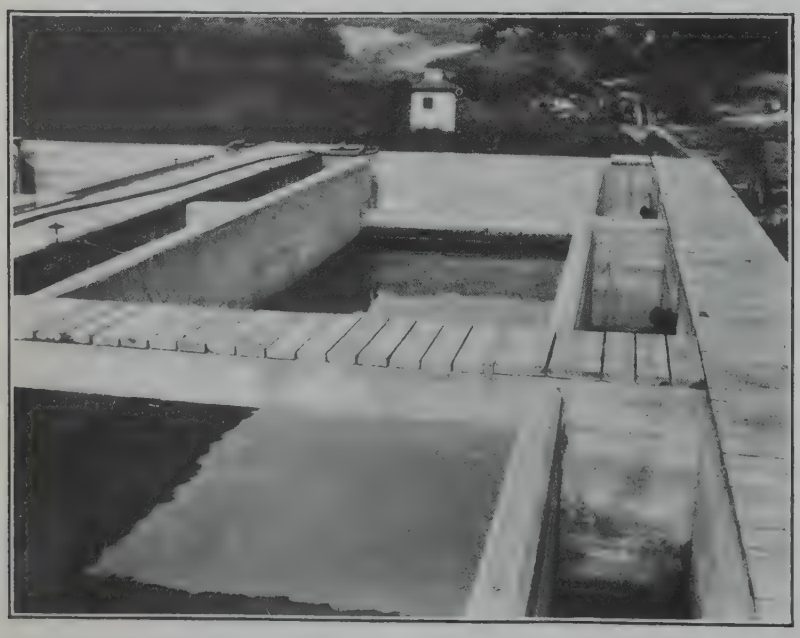
Data on sludge withdrawals should be kept. The data should include the date of withdrawal; the amount of sludge drawn; the quantity of dry sludge which is yielded and the quality of the sludge, and the moisture content of the sludge. The latter is determined by weighing a quantity of the wet sludge and then drying it. The loss of weight represents the moisture content.

Testing Condition of Sludge.—The digestion of sludge is affected by its alkalinity or acidity during digestion. Sludge digestion should take place in an alkaline condition. Some knowledge of the condition of the sludge can be secured by testing it with litmus paper, litmus being blue in an alkaline medium and red in an acidic medium. However a much better knowledge is secured by means of Hydrogen Ion Determinations. The results of this test are expressed as pH numbers. Neutrality is indicated by a pH of 7.0, anything less than a pH of 7.0 is acid and anything greater than 7.0 is alkaline. Sludge digestion is most favorable with a pH of from 7.2 to 7.4 and if the pH falls below 7.0, foaming is apt to occur. Hydrogen ion determinations are made coloremetrically. Dyes are used as indicators and comparison is made with standards of a definite pH. Complete outfits are available which make this determination very simple.

Test of Efficiency of Treatment Plant.—Probably the most reliable test of a treatment plant's efficiency is the test for the biochemical oxygen demand of the sewage. This determination measures the oxygen required to stabilize a sewage. Unfortunately, this determination is rather difficult to make, but an intelligent operator can learn the technique. If it can be made on the raw sewage and on the effluent from the plant, the decrease in the B.O.D. can be easily computed, and from this a knowledge of the efficiency of the plant and the suitability of the sewage for discharge into a watercourse is obtained.

A simpler test for judging the quality of the effluent from a plant which has complete treatment is the methylene blue stability test. This test is made by adding methylene blue indicator to a bottle containing the effluent from the plant and noting the number of days necessary for the solution to decolorize when the temperature is maintained at 70° F. or 20° C. The following table gives the relative stability in terms of the days necessary for the solution to decolorize.

Time required to decolorization at 20° C. (Days)	Relative Stability (Per Cent)
0.5	11
1.0	21
1.5	30
2.0	37
2.5	44
3.0	50
4.0	60
5.0	68
6.0	75
7.0	80
8.0	84
9.0	87
10.0	90
11.0	92
12.0	94
13.0	95
14.0	96
16.0	97
18.0	98
20.0	99



View of Portion of Sewage Disposal Plant of Teaneck, N. J.

It has been found that this test is of little value in judging the quality of the effluent from an Imhoff tank unless secondary treatment is employed. Precaution should be observed not to add an excess of the methylene blue indicator since an excess of the indicator prevents the decolorization of the solution in the time at which it would normally occur and this gives fictitious results.

Determining Daily Flow of Sewage.—Another record which should be kept at the plant is the daily flow of sewage. It is hardly practical to install Venturi meters at the smaller plants for measuring the flow. However, an approximation can be obtained by several methods. One of these is by means of a stroke counter attached to the dosing chamber. From the capacity of the dosing chamber and the number of discharges, an approximation of the sewage flow can be obtained. Another way of roughly approximating sewage flow is by measuring the depth of sewage in a sewer and computing the flow from this and the size and grade of the pipe.

Of course, a convenient record of the test should be made. The value of the tests is increased greatly if permanent records, always available for reference, are kept. Standard forms for keeping of records will be furnished by the State Board of Health.

No attempt has been made to describe the determinations for the ammonias, nitrates, nitrites, chlorides and fats. These tests are of course of value but require a trained chemist to make them. It is believed that the tests outlined above are of greater value as routine determinations for the plant operator. The State Board of Health will be glad to render all possible aid, in the way of instructing operators in the making of tests, to plants which buy the necessary equipment.

Acknowledgment.—The foregoing is a paper presented at the 5th annual meeting of Missouri Water and Sewage Conference held at Chillicothe, Mo., Oct. 21-23.

New York City to Have Municipal Sanitation Commission.—The voters of New York City at the election last month approved a proposition for the establishment of a municipal sanitation commission. The plan provides for the consolidation of several existing city agencies under one head with broad powers over sewage disposal, garbage disposal by incinerators, and elimination of beach pollution. The mayor has power to appoint and remove members of the commission, which will absorb the street cleaning department. The chairman of the commission is to receive $25,000 a year.

The Good Will of the Consumer

Superintendents' Round Table Discussion at Toronto Convention of American Water Works Association

THE best way to handle your consumer is to have a good looking girl at your inquiry window. You cannot beat that combination if she has a nice face and a soft, pleasing voice, because the customers will go away smiling after they have made their complaint. I would rather have a woman handle my consumers than a man. Of course, I always have a man handy so that when it comes down to an argument he is there to explain things, but when you are taking the consumer's money I think a pretty and sweet girl is a combination that cannot be beat.—W. S. Patton, Ashland, Ky.

We have a lady cashier and a man cashier, and they work side by side. The man takes care of the lady customers and their complaints, and the lady takes care of the gentlemen customers and their complaints.—W. S. Cramer, vice-president and manager, Lexington Water Co., Lexington, Ky.

I have found that when you have a dissatisfied customer, in 99 per cent of the cases the best thing is to let him have his say. There is an old saying that if you give a calf plenty of rope he will hang himself. That will pretty well work out in the case of a dissatisfied customer. If you can get him to talk and talk and after he is run down, open up your battery, you will find that the problem is 75 per cent decided. Of course, sometimes the women folks never do run down, but I agree with Mr. Cramer that it is a good thing to have a gentleman look after the complaints of the ladies. I think it is a great mistake to try to argue with a dissatisfied customer.—James E. Gibson, manager and engineer, Water Department, Charleston, S. C.

We send our bills out quarterly, and we read the meter monthly. The object of the monthly reading of the meter is to see that the meter is registering properly, and if we have a very high reading we will notify the customer or leave a card asking them to examine the meter and see if the reading has been correctly taken. Sometimes we send a man to examine the premises, because in that way you will frequently discover a leak. It makes the customer feel satisfied when he discovers that you are taking an interest in his supply. —S. H. Taylor, superintendent, Water Works, New Bedford, Mass.

Some years ago our office staff consisted entirely of men. When a customer came in and saw all men there he would become angry in making his complaint. We decided to employ ladies to collect the bills just for that reason, and we found that it made quite a change. It is a difficult problem to solve when your customer has a bill for $10 and the next one is for $90 and I think it is better to adjust that bill. That customer will never be satisfied if you make him pay that bill, even if you are sure that the water has been used. Do not make the mistake of settling these big bills yourself, or you will have a lot of trouble. The best way is to refer them to somebody else and let them do the settling. We had one customer who came to us frequently with complaints. He had tenants and he never looked after them. We have a practice that when we have a large bill like that in a complaint we issue what we call a customer's complaint, irrespective of whether any complaint has been made or not, and we try to find the reason for the big bill. Usually the girl in the office can make any adjustments when a complaint is made. The heads of departments have no right to give any favors to one customer or another. If one taxpayer uses water carelessly there is no reason why all the rest of the taxpayers should stand the brunt of his carelessness or dishonesty.

It is very poor policy to make adjustments, particularly in a municipal plant. I take the position that in the municipal plant your duty is to serve the public. If you show consideration for one man you should do the same to all. In a private plant if you show consideration to one man, you are simply giving the money of your stockholders away. In a municipal plant you are giving away the municipal funds. At Charleston, a number of times the question has been raised of rebating a high bill as much as 50 per cent. In every case our attorneys have advised us that that is discrimination and cannot legally be carried out. We have three commissioners on the Commission who have paid $90 water bills. When they come to me and ask for an adjustment I tell them that one of the Commissioners has had to pay a $90 bill and that I have no authority to make an adjustment. If they would like to bring the matter before the Commission I would be glad to have that done. Of course, when the matter is brought before the Commission the consumer receives every courtesy and consideration, but the complaint is disposed of in the usual manner, which means that the consumer pays the bill. In one or two instances of these high water bills the consumer does not pay it all at once, but he pays it in small amounts, $1 a quarter, and if he keeps on paying he will get it settled in about 12 years. It usually works out that after he has paid two or three months he gets tired doing that and he wipes out the bill.—J. E. Gibson.

The original question was that of courtesy and good will. I think we all realize that large bills are the paramount factor in dissatisfaction. Originally we used to read the meters and collect monthly all our water bills. Before I went to Omaha they changed over and read the domestic meters every three months. As a consequence, where a leak occurred that was inaudible and invisible, they would make a two-thirds reduction on the bill. Later on we changed that to a two-thirds reduction, assuming that the leak had been found the first month. It makes no difference whether the consumer is a poor laborer or a millionaire, we make the same reduction. In addition to that, whenever a meter seems to be running a little sloppy, and what we think is beyond normal, we notify the tenant that the bill is abnormally high and suggest to him that he look for a leak. We send our inspectors out to find out if there is a leak. I think the biggest factor in regard to courtesy and goodwill is to have a perfectly fair and open discussion with the party who comes in making the complaint and explain to the very best of your knowledge and with patience all the facts in connection with the matter. Try to show him why his bill is high. I think an explanation goes a far way with a reasonable man. Another strong factor is to have employees who have a pleasant manner and a nice method of explaining things.—Theodore A. Leisen, General Manager, Metropolitan Utilities District, Omaha, Neb.

We find one of the best methods of explaining to a customer the reason for a high bill is to check his meter, and follow that up by sending an experienced man to look it over. He takes the customer to the meter and shows the water being registered on the test dial. To show you how it works, we had one of our railway companies that had a 2-in. hose that was left lying on their platform. Several million gallons were wasted in 30 days. The management were not aware that that leak existed. We investigated the matter and found the leak. We found that the man who looked after the water supply had repaired the leak, but we sent the bill into the railway company. Word came back that the bill was out of all possible bounds, and then we gave them the time and date when the leak had occurred and that settled the matter. We have had similar cases in domestic services. Flush tanks in houses are a common source of trouble

because a leak of that kind is something that the householder cannot see, but our expert can take the customer to that tank and show him where the leak is, and show him how it is registering on the meter.—A Member.

Some one in the organization ought to assume responsibility for these matters and settle them there and then. I think the facts should be looked into and the matter thoroughly investigated and before our customer gets to us with a complaint we have the facts looked into. When the customer comes to me I can make what adjustments are required.—S. B. Morris, Chief Engineer, Water Department, Pasadena, Calif.

I have heard a great many things about meters and I want to tell you something that happened last year to one of our best customers, whose bill jumped from $1 to $15 in a month. He came down to see what was the matter, and we called on the old gentleman and asked him what he had done and he said nothing at all. The next month the bill was still $15. We sent a man out to look at the meter. While he was there a man came along with a load of watermelons, and the old gentleman bought one of these melons. Our man said to him, how do you cool that melon, and he said I set it up in the sink and turn the faucet on and let the water run all night; so he paid his $30 for the two months. We rebate all bills that are too high if it can be shown that there is some reason for it. A customer came into the office the other day and talked to the young man who was in charge. He said his bill was $13 and it had never been over $2.25 before. He wrote a letter to the commission and it was referred to me. He came in and I said to him I understand you are real mad about this. I said sit right down and give me all the excuses you have and when you get through I will begin to talk. He commenced to laugh and he said what do you want me to do. I said I want you to go back to your house, and in the morning I will send our man out and he will take your meter out and take it to the testing plant. If that meter is 2 per cent high we will give you this $13 and if not we will make you pay the whole bill. If the meter is wrong we will not charge you. He did not know about that, and I said, do you know what caused that meter to register that amount of water, because meters seldom make mistakes. We sent the man down and found that the meter registered ¼ of 1 per cent under. We charged him the regular rate and split the difference on the other, and that was perfectly satisfactory. We had one case about five years ago where a man had three houses on one meter, and his bill had been running $15 to $18. We could not find what was wrong and he had his entire pipe line taken up. He finally found there was a leak in his flush tank that nobody knew anything about. I do not believe in giving a rebate for one or two months, because if you tell a man that you will rebate one time, he will come back for a rebate again. Is there any one here who has the system of leaving a card at the residence where the people are not at home, and have the customer fill out the reading of the meter?

There was an old rule in our department to compel our consumers to lay their pipes 18 in. underground in the cellar. That was in the early days. In about 50 per cent of the cellars the soil will vary. We find that leaks will occur in these pipes underground. We had one man who was troubled that way and I thought he should get consideration. Our board has reasonable discretion in matters of that kind and tries to make a uniform 50 per cent allowance, but not the whole bill. We charge the consumer the amount of his former bill and allow him 50 per cent of the excess bill. I believe the bills that are sent out are pretty nearly correct. We have one man who pays a bill of $396 or $450 a quarter without any question. —James Sheehan, Memphis, Tenn.

Cost of Water Purification at St. Louis, Mo.

In his annual report for the year ending April 1, 1929, August V. Graf, Chief Chemical Engineer, Supply and Purifying Section, gives the following information on the operation of this water purification plant of St. Louis, Mo., for the year.

During the past year 47,269 million gal. of water were pumped into the basins. To this amount of water were added 1.924 tons of sulphate of iron and 15,816 tons of lime, or an average of 0.57 grain per gallon of the former chemical and 4.68 grains per gallon of the latter. Aluminum sulphate to the amount of 171 tons was used at the Coagulant House during the year and the cost of this chemical is included in the cost given for iron.

To the 44,547 million gallons of water filtered were added 4,025 of sulphate of alumina and 218,000 lb. of chlorine, or an average of 1.26 grains per gallon of the sulphate and 4.80 lb. per million gallons of chlorine. All of the aluminum sulphate and part of the chlorine were added before filtration and part of the chlorine after.

The average cost per million gallons for lime was $2.81; sulphate of iron, $0.68; sulphate of alumina, $1.61; chlorine, $0.28. These costs are for chemicals alone, and do not include the costs of handling or application. A comparison of the costs of the various parts of the purification work during the past five years, based on the quantity of water delivered to consumers, is shown in Table I.

Water Works in Wisconsin

Of the 2,631,839 people in Wisconsin, 1,423,989, or approximately 54 per cent, are served from public supplies. A study of the sources of supply shows that 30 municipalities, representing a total population of 755,820, secure their water from surface sources; 13, with a population of 211,762, with complete purification; 16, with a population of 543,207, with partial, and one with a population of 851, with no purification. One hundred and seventy-nine other municipalities, with a population of 483,674, secure their supplies from deep wells, and 73 with a population of 184,495, from shallow wells. All well supplies, except four, serving a combined population of 8,236, are without purification. In these four supplies, the waters have been found polluted and are therefore sterilized with liquid chlorine. While only 30 municipalities secure their water from surface sources, this represents about 53 per cent of the population served from public supplies, while approximately 34 per cent are served from deep wells and 13 per cent from shadow wells, indicating that 29 per cent of the state's population is served with water from surface sources, 18 per cent from deep wells and 7 per cent from shallow wells.

Table I—Cost Per Million Gallons—Based on Consumption 1928-1929

Old Plan	1924-1925	1925-1926	1926-1927	1927-1928	1928-1929
Lime	$ 3.57	$ 3.07	$ 2.53	$2.22	$2.81

Progress in 1929 in the Art of Sewage Disposal

Grit Chambers—Detritus Tanks—Sedimentation Tanks—Aerating Devices—Activated Sludge—Chlorine and Sewage Disposal—Sludge Treatment—High Temperature Digestion—Tendencies in Design

By JOHN R. DOWNES
Associate Editor, Water Works and Sewerage

THIS article is an attempt to indicate the latest developments in the design, construction and operation of sewage disposal works and, also, the trend of thought which will influence the designs of the near future.

It is impossible to precisely cut off, and set apart, each year's progress from that of any other year or to ascribe definite developments to certain persons, because the present status of the art has been arrived at by the exchange of ideas over a long period of time. For instance, Waldo S. Coulter of New York, in speaking of one of his latest developments, is able to trace the idea back to the work of Prof. Chas. Gilman Hyde of California in 1926. Meantime Cohn of Schenectady and Hommon of Canton, O., have worked along the same line. More often ideas are subconsciously absorbed and honestly claimed as original by one person much to the chagrin of another who has been possibly hiding his light. All of which makes an article of this type a precarious undertaking and your indulgence is asked accordingly.

Grit Chambers.—In the past much thought has been given to the design of grit chambers with the idea of making a nice distinction between inorganic grit and readily settleable organic solids. The objects of removing the grit are:

To prevent unnecessary wear on pumps, and fine screens.

To prevent clogging of valves and about the base of sludge pipes.

To make available for active digestion processes, space which would otherwise be occupied by the inert grit.

The object of making a nice distinction between organic and inorganic solids which may be collected in a grit chamber, is to leave the grit in such condition that it may be used for fill, or otherwise disposed of, without its becoming offensive to the olfactory nerves.

A development of 1929 is the realization that much of the organic matter which tends to separate at this point may well be disposed of here with much benefit to the balance of the disposal works. This is particularly true since the art of brewing has been transfered from the public brewery to the private home. The spent mash is very heavy and very acid and productive of the most offensive odors which ever occur about the plant. The mash material is almost the equivalent of sand in its clogging effect. Together with mash, a grit chamber tends to collect a mass of large sized vegetable debris, the kind of material which forms scum blankets on settling tank surfaces.

The difficulty of designing a grit chamber to separate only clean, inorganic sand under the tremendous variations of flow encountered in sewage work is too well known to require comment. The economy and convenience of keeping this heavy organic matter out of the sedimentation tank is just beginning to be realized.

The realization of this situation will result in the hydro-mechanical washing of the comparatively small volume of collected grit instead of trying to control the whole, widely varying flow of sewage to so precise a velocity as is required for the proper classification of the grit.

Screens.—The year 1929 seems to have produced little that is original in the screen line.

Alvord, Burdick and Howson, report the installation of a mechanically cleaned bar screen at Aurora, Ill. In this installation the cleaning mechanism operates only when a predetermined difference of head is established between the two sides of the screen. This screen is on a combined sewer and the mechanism operates once in 4 to 5 minutes during storms and only once in an hour or two at other times. More effective screening is thought to be obtained by allowing material to build up a mat on the screen.

Detritus Tanks.—Developing still further the idea suggested under the heading of "Grit Chambers," there is, at present, a marked tendency to introduce skimming and detritus tanks ahead of the sedimentation units. The leading engineers are introducing this feature in nearly all of their designs for larger plants.

Sedimentation Tanks.—Imhoff tanks are still a feature of a number of large designs by leading engineers. Metcalf and Eddy have included Imhoff tanks in plants for 250,000 persons at Akron, O.; and at Dayton, O., and for 128,000 persons at Allentown, Pa.

More and more attention is being given to distribution of flow in sedimentation tanks by the use of high velocity inlets in place of the old open channels and by the introduction of lattice baffles.

Waldo S. Coulter has reverted to the old septic tank provided with lattice baffles and has interposed between the settling tank and such further treatment as may be provided, a 2-story "trap" tank to intercept solids unloaded by the primary unit. Agitation by dropping the primary tank effluent onto a splash board at the entrance of the trap tank, releases entrained gases and allows the solids to settle.

Mechanical removal of the deposited solids from settling tanks is gaining considerable headway as it is bound to do when we realize the importance of prompt and effective removal both to the quality of the tank effluent and to the efficiency of solid digestion.

Aerating Devices.—As primary oxidizing devices the contact bed and the sand filter seem to be ruled out of the modern picture by the very conditions which impose a demand for sewage disposal; that is to say by density of population and high land value.

The year 1929 finds the sprinkling filter still with us and likely to stay for a few decades. This very useful device with its marvelous recuperative powers and its ability to withstand abuse, has, indeed, had its prospective useful life extended by the very system which for a time seemed destined to replace it. Pre-aeration, not only extends the life of the sprinkling filter, or increases its capacity, but also makes possible the control of such odors as have heretofore been more or less definitely associated with trickling filters.

Trickling filters are features of the larger designs for 1929 by the most prominent engineers and, we believe, rightly so. The trickling filter fly has last its terror, since complete control of this nuisance is possible through systematic filter flooding operations. This flooding, which at first threatened to decrease the overall efficiency of the filters, has been developed to a fine art and now actually increases the year around efficiency and makes the periodic unloading problem much less acute. Needless to add that proper provision for flooding is an essential part of the modern design.

Activated Sludge.—It has been said that success for the activated sludge

system appears to be just around the corner; and yet the largest plants now being designed contemplate the use of activated sludge. This is because local conditions of population and land values activated sludge as the only alternative, and makes it necessary to face the problems of power cost and sludge disposal. These large designs provide very flexible arrangements for sludge disposal and the proper solution seems to be only a matter of time and experience.

Power costs are being cut in a few instances by using the gas from the digesting sludge to operate the air blowers. This method has been in use at Plainfield, N. J., for the past two years for operating the aeration unit in summer.

Chlorine and Sewage Disposal.—Some very valuable information gathered by the Chlorine Institute during the past two years has been put to the test during 1929 and chlorine equipment for prevention of odors has practically become standard.

We now have very definite information about the equation by which chlorine oxidizes volatile and odiferous by-products of sewage decomposition to either non-volatile or non-odiferous compounds. Also, we are able to apply the chlorine at the proper point to prevent the odorous compounds from forming or escaping into the atmosphere.

Sludge Treatment.—So far this article has dealt with the treatment of the liquid portion of the sewage. However, the really difficult part of the problem is still, as it has always been, the reasonable and non-obnoxious disposal of the solid material. Near the close of the present year the announcement was made in Philadelphia that the problem of sludge disposal had been met by the invention of a process for drying and incinerating the raw sludge as it comes from the settling tank.

While this announcement was made with all the authority of the Bureau of Surveys of the City of Philadelphia behind it, engineers who heard it, were frankly skeptical of the economy of drying and incinerating 95 per cent moisture sludge.

True, certain work of the New Jersey Experiment Station had indicated, some time ago, that theoretically there is sufficient fuel available in the green sludge to provide for its drying and incineration. There seem to be many difficulties, however, in making this theoretical fuel value available.

High Temperature Digestion.—While Philadelphia is pursuing this investigation further, the New Jersey Sewage Experiment Station is carrying out experiments on high temperature digestion which promise to reduce the time of digestion from 40 days at 70° F., to 10 or 12 days at about 125° F.

Below is a statement from the laboratory on the present status of this work. The point is, of course, that the per capita allowance of sludge space can be reduced to about one-third that required for controlled digestion at 70° F.

"Investigation on Thermophilic Digestion.—The digestion of settled solids at a temperature range of 115-130 has been accomplished. At this temperature common bacteria capable of growing at ordinary temperatures are killed off and a new group of heat-loving (thermophilic) organisms established. These organisms are present originally in sewage solids in limited numbers in an inactive state. When the temperature is raised to 115-130 these organisms multiply slowly and replace the original flora. When the fresh solids are seeded with ripe sludge produced at low temperatures (70° F.) there is a period of biological adjustment and consequently low rate of activity. Once the thermophilic flora is established the decomposition proceeds rapidly. Thus with sludge produced under thermophilic conditions the digestion of fresh solids has been completed under laboratory conditions in 10 to 12 days at 122° F. The yield of gas and the reduction of volatile matter are somewhat higher while the composition of the gas is similar to that obtained with normal temperatures."

Controlled digestion at 70° F. has become an established and effective practice, cutting the time required for digestion from 100 days plus, to 36 to 40 days. The absolute safety with which the methane gas can be collected under floating covers as used at Springfield, Ill., Elyria, O., Plainfield, N. J., Mammaroneck, N. Y., makes the problem of maintaining the 70° temperature very simple.

Samuel Greeley of Pearse, Greeley and Hansen, Chicago, points to the development of inexpensive winter storage for ripe sludge in connection with controlled, rapid digestion as an outstanding feature of his firm's work.

The provision of inexpensive winter storage of ripe sludge is being accepted as a stop gap pending the development of real winter drying, either mechanically, or on sand beds under cover.

In the combination of rapid digestion followed by cheap storage, the sludge is first digested in a well insulated tank provided with a safety floating cover. Heat is cheaply produced from the gas evolved in the process. After the first 36 to 40 days, the sludge is non-offensive and ready for drying. It may then be removed to uninsulated, uncovered, tanks or to lagoons to await spring drying weather. The cost is far less than can be secured by providing Imhoff digestion compartments for winter storage.

Tendencies in the Art.—This development is in line with the tendency of most of the best engineers to make the new designs flexible so that the plant can be inexpensively enlarged or adapted to new developments as their merits are demonstrated.

A note from Fuller and McClintock indicates that they are giving more and more attention to flexibility in sewage treatment and are tending to divide the process into a number of small steps.

Fuller and McClintock's design for the Wards Island plant for upper New York City provides for sedimentation ahead of activated sludge which seems to be an accepted American practice where activated sludge is used. For the present they provide for barging the sludge to sea, while experimenting with the possibilities of fertilizer production.

This same firm provides for barging sludge to sea in the case of New Haven, Conn. At Tenafly, N. J., they report success with the direct drying of the fresh excess activated sludge under glass.

At Middletown, N. Y., this firm is completing a plant where the sludge will be digested in heated, controlled digestion tanks with safety floating covers and will be dried under glass.

From the southwest, Black & Veatch of Kansas City, Mo., report a trend towards activated sludge in their designs. Preliminary sedimentation is consistently included in these designs, as is controlled digestion of both primary and excess activated sludge.

This firm is struggling with the old problem of effective resedimentation following trickling filters, and at Newton, Kan., have added an equalizing tank with a view to producing a nearly uniform flow in the final tank in place of the surges characteristic of trickling filter discharges.

Alvord, Burdick and Howson report a decided trend toward separate, controlled digestion in all their designs for 1929. They report that at Fond du Lac they are consistently securing approximately two-thirds of a cubic foot of gas per capita with variations from 0.6 to 0.75 cu. ft. per capita. This firm stresses flexibility in its new designs and reports that at Aurora particular attention was given to landscaping and a cheap and effective Spanish stucco type of architecture was used to include all pumping, sedimentation and digestion units under one roof.

Reading of English literature and reports of returned travelers from Germany, give the impression of some bitterness of feeling between the proponents of various types of disposal works in those countries. In this country engineers seem to adopt whatever equipment meets the peculiar needs of a particular locality without prejudice. The free and ready interchange of information among engineers in this country has always been a source of wonder to foreign visitors. The great number of Sewage Associations started during 1929 will further the friendly feeling among workers in the sewage field and lead to still freer interchange of information, much to the benefit of the art.

Leveling for Tunnels and Reservoirs

How Surveys Were Made for the Swift River Reservoir Project of the Boston Metropolitan District Water Supply

By LAROY G. HARRIS

Assistant Engineer, Metropolitan District Water Supply Commission, Barre, Mass.

THE base for the levels run on the Boston Metropolitan District Water Supply Project was established, in connection with the U. S. Coast and Geodetic Survey, by running a series of "precise" or "first order" levels from an established Government bench-mark at Springfield, Mass., along the railroads to Boston via Oakdale, Mass. This established a base line from which circuits and spurs were run in and around the proposed Swift River Reservation Basin and to the various shaft sites along the tunnel line from the Wachusett Reservoir to Swift River.

Bench-Marks.—The following rules were followed strictly:

Permanent bench-marks were established at intervals of approximately 2 miles. The line of levels between two bench-marks was broken by temporary bench-marks into sections from 3,000 to 4,000 ft. long, except where special conditions, such as the extremely hilly country which was encountered on some of the cross-country runs, made shorter sections advisable.

The line of levels is broken in this way in order that an error between two permanent bench-marks can be located without re-running the entire distance of 2 miles. This saves considerable time in case an error is made, especially in hilly country where progress is comparatively slow.

No bench-mark was established and designated as permanent unless it was so fastened in rock, brick, or concrete as to resist extraction, change of elevation, or rotation.

At places from which it is likely that future leveling will be extended, at least three bench-marks should be established within a radius of about ½ mile, or far enough apart not to be affected by the same disturbing cause or causes.

Leveling. — Except when specific instructions are given to proceed otherwise, all lines are to be leveled independently in both the forward and backward directions. It is desirable that the backward measurement on each section should be made under different atmospheric conditions from those which occur on the forward measurement, and this is usually accomplished by making the backward run in the afternoon if the forward run is made in the forenoon, and vice versa.

If the atmospheric conditions seem to remain the same throughout the day, the observer should secure as much difference between the forward and backward runs as is possible without materially delaying the work for that purpose.

On all sections on which the forward and backward runs differ by more than the accepted allowable error, which is generally $0.02\sqrt{K}$ (in which K is the number of miles), the section should be re-run until any two runnings in opposite directions check within the limits of the formula.

The length of sight is usually determined by the topographic and meteorological conditions, but should never exceed 400 ft.

The length of sight between the forward and backward stations should be kept as nearly equal as possible by pacing.

When it is expected that the forward and backward runnings of the line are to be completed up to any one place, the elevation at that place should be held by two temporary bench-marks, established at least one set-up of the instrument apart. When the leveling is continued from or to such a pair of points, the instrument should be set up between them and rod readings taken on each point. The same arrangement of points should be used at the completed end or ends of any detached portion of the line of levels. Either one of the two points may be used for carrying along the elevation, with the other used only as a check against mistakes in reading the rod, or a disturbance of one or both of them. By this method, no mistake of a foot made in reading the rod, held on a bench-mark, will escape detection.

The party consisted of five men: Chief of party, observer, recorder, two rodmen, and an umbrella man. The instrument used was a Berger 3-wire Wye-level. The Molitor rods were used, and these rods have shown, after various tests, that no rod corrections were necessary. Steel turning points were used at all times, except when running along railroad tracks; then common tenpenny wire nails were driven into the ties and the head was used as a turning point. The steel turning point was driven into the ground with the aid of a hammer. After the rod readings were obtained as the back-sight the rear rodman pulled his steel pin and moved forward.

Bench-Marks.—The bench-marks used were of two types, one being a ¾-in. round, brass rod, 6 in. long, rounded on one end. The shank of the rod was threaded for a length of 3 in. These rods were grouted in large boulders, ledge outcrop, and concrete bridge abutments.

The other type of bench-mark was an iron rod about 5 ft. long and bent on one end. A hole approximately 18 in. in diameter was dug in the ground for a depth of 5 ft., and there filled to a depth of at least 18 in. with concrete. The rod was embedded in the concrete in a vertical position, bent end down. After the concrete had set, at least 24 hours, a piece of 2-in. pipe was set around the rod, resting on the concrete, so that the top of the rod was about ½ in. below the top of the pipe. A cap prevented the admission of water, and the hole around the pipe was refilled with earth.

All levels for this work were run during the summer months. It is not generally considered good practice to run precise levels during freezing weather as all tripod legs are fitted with metal points which absorb heat and cause more or less settlement when set on frozen ground. Then, again, it is practically impossible to drive steel pins into frozen ground and steel plates are not wholly dependable, as they will also move if left too long on warm days.

The umbrella is used only when the sun is shining brightly enough to cast a shadow. The idea of the umbrella is to keep the sun's rays from affecting the instrument by expansion. When the instrument is being carried from one station to another it should be protected from the sun by covering it with a cloth or canvas hood.

Equidistant Sights.—When leveling cross-country in hilly territory it is practically impossible to keep the instrument equidistant from the back-sight and fore-sight, but the recorder should keep the observer well informed as to these differences so that he can equalize them as soon as possible. If the fore-sight is, say, 100 ft. longer than the back-sight, then the observer, on the next set up, should shorten up on the fore-sight enough to correct this difference, without any expenditure of time for this particular purpose; so at the end of the run the total lengths of the back-sights should approximately equal those of the fore-sights.

The back-sight is generally taken first and the observer reads all three cross-hairs beginning with the top hair. They are read in feet, tenths, hundredths, and thousandths, and immediately recorded. The fore-sight is read likewise as soon as possible after the back-sight to avoid any possible error due to settlement of

the instrument. The wire intervals are immediately worked out by the recorder, and if they do not differ by more than 0.006, which was selected as a maximum, the instrument was moved ahead to the next station. If the wire intervals differed by more than 0.006, the readings were taken again. On some jobs the wire interval is allowed to vary with the length of sight from 0.004 to 0.010, but they were kept low on this particular work for more or less of an experiment, and the final results showed that the error of closure and the percentage of re-running was kept comparatively low without sacrificing speed.

Progress.—The speed in leveling is greatly dependent upon the activity of the observer, the topography of the ground covered, and the meteorological conditions.

The following tabulation shows the speed attained on this work and is based on levels run in and around the proposed Swift River Reservoir Basin. It does not include levels run along the main line from Springfield to Boston:

Working days	45
Average working hours per day	6.75
Total mileage (including "re-runs")	135.0
Average number of miles per day	3.0
Maximum number of miles any day	7.0
Average number of miles per hour	0.44

The average divergence in the forward and backward runs between adjacent benches on double-run lines was 0.0085 ft., giving an average error of closure of $0.009\sqrt{K}$. The average error of closure for single-run circuits (loops) was $0.01\sqrt{K}$. Of these 135 miles, 7 miles, or approximately 5 per cent, were re-run.

Acknowledgment.—The foregoing is a digest for the December Proceedings of the American Society of Civil Engineers of a paper presented by Mr. Harris at the Fall meeting of the society.

Pacific Northwest Water Works to Meet in April

At a meeting of the board of directors of the Pacific Northwest Section of the American Water Works Association held on Nov. 2nd, 1929, at Portland, Ore., it was decided to hold the next annual meeting on April 24th, 25th and 26th, 1930.

At the present time it is planned to hold a golf tournament on April 24th, the presentation of papers and business meeting on April 25th, the dinner meeting and entertainment on the evening of April 25th, the inspection trip covering the local water system, including trip to the Bull Run Dam and headworks, together with other features, on April 26th.

In connection with this annual meeting the following committees were appointed:

Program: Messrs. W. A. Kunigk, chairman; Carl F. Klapp, and R. E. Koon.

Registration and Reception: Messrs. R. J. Disher, chairman; R. T. Wetteland, Sydney J. Benedict and Chester G. Ehle.

Local Arrangements and Entertainment: Messrs. John S. Beall, chairman; H. M. Chadwick, R. C. Polk and E. N. Hallgren.

Golf: W. B. Severyns, chairman; R. H. Corey, E. W. Thompson and Sam Kerr.

Transportation: H. A. Goode, chairman, and C. J. Wagner.

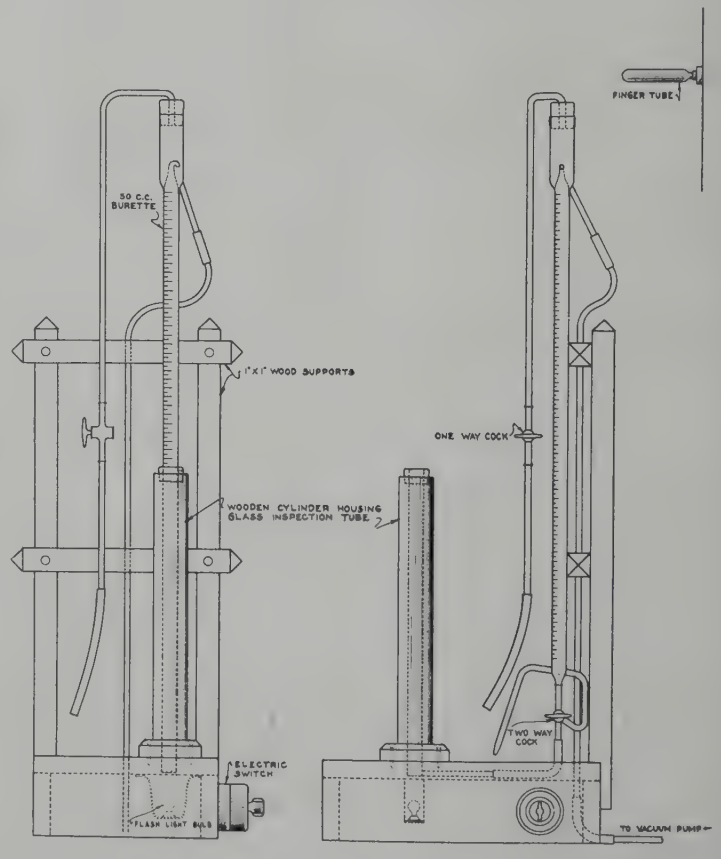
Ernest C. Willard, 720 Corbett Bldg., Portland, Ore., is secretary of the section.

Magnesium Turbidimeter

The hardness of water at the Chain of Rocks filtration plant, of St. Louis, Mo., is calculated from the amounts of calcium and magnesium determined. The method used is that given by Thresh in "Examination of Water & Water Supplies." The calcium is precipitated as oxalate and the amount determined volumetrically. The magnesium is precipitated as magnesium ammonium phosphate and the turbidity produced is determined in the turbidimeter shown. This turbidimeter was designed by F. S. Hawken, Assistant Chemical Engineer. The use of this turbidimeter is described in the last annual report of Leonard A. Day, Water Commissioner of St. Louis.

The sample is drawn, by the vacuum pump, into the burette through the tube connected to the two-way cock. The one-way cock is opened and enough solution is allowed to flow through the two-way cock to fill the small tube connecting the burette to the glass inspection tube. The burette is again filled to the zero mark. The light (a 3.8 volt flashlight bulb in series with a 110 volt, 8 c. p. finger tube) is lit and enough solution is added to obscure the filament of the lamp. This determination is repeated as a check.

A standard containing a known amount of magnesium is precipitated and run at the same time. The standard is so adjusted that practically the same amount of solution is necessary to obscure the filament as is the case with the sample. From the amounts needed to obscure the filament in each case, the amount of magnesium in the sample of water can be computed. This method yields results in practical agreement with those obtained by the gravimetric method.



Details of Magnesium Turbidimeter

Landscape Treatment for Water and Sewage Plants

THE landscaping of the surroundings of water works and sewage disposal plants has been dealt with rather sparsely in engineering literature. At the Third Annual Conference (1929) of the Maryland Water and Sewerage Association three interesting papers were presented on the subject. They are reprinted below.

The Four Dominant Qualities for Landscape Work

By G. W. STEPHENS, JR.
Chief Engineer, The Roland Park Co., Baltimore, Md.

Surroundings of Sewage Plants.—All landscape work, no matter what its size or where it is located, to be a success as an artistic creation must have four dominant qualities, namely, unity, variety, character and finish. The surest way of obtaining the effect aimed at is to be simple in treatment. The true landscape architect aims to produce the best effect by using the smallest variety of kinds in as limited a quantity as possible.

To be permanent, the work must be done step by step in its proper sequence.

Unity.—Professor L. H. Bailey very aptly defines unity as applied to the landscape as follows: "Every planting should be a picture, that is, the area should be set off from every other area, and it should have such character that the observer catches its entire effect and purpose without stopping to analyze its parts. The planting should be one thing, one area, with every feature contributing its part to one strong and homogeneous effect." No one item should be individually conspicuous, but all should help in creating the quiet harmonious whole.

Variety.—When used in this sense I do not mean there should be many kinds of plant material, but there can and should be variety in sky line or contour, in texture of foliage, color, lawn surface, without marring the unity of the place. For instance, while all harsh color contrasts should be avoided, a dash of color here and there among the green can be nicely blended and will add interest. The various characteristic forms of growth, such as horizontal branches against the erect or vertical, make pleasant breaks and give character as well.

Character.—This quality consists largely of being individual or "different" from other places similar in size and outline. It is not easy to define, as the character of a planting is generally the unconscious "touch" of the maker. Just as the "stiffness" or "restfulness" of a room is decided mainly by the appearance and placement of furniture, so character of the planting is dependent on selection and arrangement of material. Each tree or plant should be carefully selected to harmonize, and so placed that it will merge into the general planting scheme.

Finish.—A beautiful planting or lawn cannot retain a permanent, finished effect unless it has the touch of one who is really a lover of plants; one who lives with them, watches their development, and knows their names as well as their appearance. This interest and knowledge is quickly acquired by working among your plants and trees, and personally selecting specimens. Once the flame of enthusiasm has been lighted, you will find yourself observing every planting you pass and taking note of every unusual plant, picturing a place in your planting where it would "just fit." When you have this interest, the shrubbery and flower beds will be kept edged, the lawn kept neatly cut, the hedges evenly clipped, the weeds kept out, and in general, cleanliness and tidiness will prevail. This is the "finish" of the planting.

The sewage treatment plant is commonly thought of as a place to be avoided, and I suppose it is for this reason that so little thought has been given it from a landscape viewpoint.

Heavy screen plantings of flowering shrubs should be used with a few accent points of evergreen trees and shrubs to support the deciduous plantings during the summer and add a touch of life and color during the winter. The buildings should be treated with evergreen and deciduous vines to soften them, and base plantings of flowering shrubs, both evergreen and deciduous, be planted to harmonize with the architecture of the buildings and most important to tie them to the ground.

The walks and roadways within the enclosure of the plant proper and roads leading into the plant reservation should be, in so far as is practicable, curved gracefully to soften the picture and to allow plantings to be made that will screen effectively vistas that may be objectionable from both inside and outside the plant reservation.

Surroundings of Water Plants.—The water plant presents an entirely different problem than the sewage plant. The landscaping of water plants has been given much thought and it is seldom we find the surroundings of them unpleasant.

The small plant as well as the large can be very effectively landscaped with the use of flowering shrubs, both evergreen and deciduous, together with properly arranged perennial and annual borders. By such a combination blooms can be had during all of the summer months and the evergreens will suffice to add the interest needed during the dull months of the winter.

Planting in keeping with the architecture of the buildings is an important part of the landscape setting. Charming planting effects are not the result of chance, but of the studies of men skilled in such matters, who know the soil and the climatic conditions, the growing habits of trees and shrubs, and notably the particular planting scheme to bring out effectively the beauty of architectural styles, and unity, variety, character and finish of the landscape picture most desired.

Important Factors in Landscaping

By M. J. RUARK
Bureau of Sewers, Baltimore, Md.

The following are of importance relative to the landscaping of sewage works:

1. The landscape work where possible should be carried out as part of the initial program, and the cost included in the original estimate;
2. If a sufficient appropriation for the construction of a sewage plant is not available, it is unwise to provide for extensive landscaping at the expense of providing adequate and efficient treatment units;
3. Although it is desirable that a sewage plant be attractive, even under the most favorable conditions it cannot be considered a place for public recreation;
4. Unless funds are available annually for landscape maintenance, this work is likely to result in the forces neglecting operation work in giving more time to cutting of grass, trimming hedges, pruning shrubbery and similar work.

Although the planting of trees and shrubs around and near pumping stations, screen houses and buildings is desirable, such planting, however, should not be placed in the immediate vicinity of trickling filters. Furthermore, narrow strips of grass should not be planted, as they are usually very hard to maintain. While the planting scheme should be attractive, it is doubtful whether there should be any attempt to produce elaborate effects. Dried sludge makes a good filler or substitute for top soil, and there is little difficulty in keeping the grass areas in the vicinity of a sewage plant healthy. On the other hand, the lawns may require

mowing more frequently than in parks, or water-works plants.

Even though funds are not available for a complete scheme of landscaping, nevertheless, rank grass and weeds should be kept cut, swampy areas should be drained, as they provide a breeding place for gnats and mosquitoes, and detract from the appearance of the sewage plant.

The Value of Beauty

By JAS. W. ARMSTRONG
Bureau of Water Supply, Baltimore, Md.

It is important that those entrusted with planning and designing of public improvements should have an appreciation of the value of beauty. The marked improvement in architectural and landscape work in this country in recent years, shows that public taste is gradually reaching a higher plane, and as time goes on the public will demand well designed buildings with attractive surroundings.

Public buildings and grounds are silent witnesses to public taste and have much to do with the standards adopted by private citizens in their places of business and home surroundings. I remember hearing a speaker at a convention describing the influence of good roads on a community. He told of a dirty and neglected street lined with dilapidated and shabby looking houses. The street was repaved with asphalt and almost immediately changes began to take place. Broken window lights were repaired, shutters straightened, painting was started, front yards were cleaned, grass and flowers began to appear, and in the course of a few months the transformation was truly remarkable. All because a conviction had taken hold of them that an attractive and clean street demanded the same kind of homes.

I am making a plea for those who have the planning of public works, to study the aesthetic side of your work along with the utilitarian side.

Lack of funds is the excuse sometimes offered for ugly looking places, but that is generally not the real reason, as good looks can often be secured with little or no added expense.

I have seen buildings and grounds with much money spent on them, obviously for the purpose of adornment, that were ugly; and othere that were made beautiful simply by a skillful massing and proportioning of the buildings and by observing a few simple requirements for planting. If the matter of beauty is not kept in mind during the designing period, it will probably be impossible to remedy the trouble later. I know of a public building recently constructed that was so unsightly that the neighbors complained of it. The officials in charge are now making an effort to remedy the trouble by plantings, but their efforts are too late to ever secure any pleasing effect.

Many city employees inherit ugliness in the surroundings under which they are required to work. Their problem is a very different one from the designee, yet some of the same principles may be applied to the improvement of their places. By the judicious use of a little money and a vision of the possibility of beautifying a place, a plant superintendent may become a real public benefactor.

A few simple suggestions may be of service. An unattractive looking building may be transformed into a thing of beauty by covering it with vines, such as the Boston Ivy or by planting the Boston and English Ivy together, whereby a touch of green may be maintained through the winter. An unsightly building, a coal or ash pile, may be screened from public view by planting closely around it such trees as the Lombardy Poplar, and in front of these may be planted tall growing flowering shrubs, and in front of these shrubs of lesser height. In this way a mass of beautiful foliage can be secured at very little expense. In planting small areas, it is always well to preserve as much lawn surface as possible, and if trees and shrubbery are planted around the borders of the property and in the back ground with occasional plantings against the buildings, a much more attractive appearance will be secured than if the center of the lot were cluttered with trees and bushes.

The unexpected sight of a beautiful tree or cluster of plants or a vista revealing a beautiful view that could not be anticipated always add to the charm of a landscape. The element of surprise which generally enhances beauty can be better secured by making the outline of planning follow irregular curves than by using straight lines. Before an attractive appearance can be secured in some places, it is necessary to regrade the grounds. In such cases, it should be remembered that steep terraces with sharp horizontal lines at the top and bottom are not pleasing to the eye and are seldom found in nature. Gentle slopes with curves at the top and bottom look better, are less expensive to maintain and they also permit the easy operation of lawn mowers.

If terraces must be maintained they can be beautified by the close planting of shrubs. Those who have observed unsightly paths across parks and public squares, know that most people, whether they have studied geometry or not, realize that the "shortest distance between two points is in a straight line." Such paths may be prevented in one of two ways. By plantings that prevent short cuts or by making walks follow the natural lines of travel. Walks following gentle curved lines are more pleasing than straight walks, provided the curves do not give the appearance of being uselessly introduced for effect.

Broad leaved deciduous trees are objectionable for planting around open reservoirs for the reason that the leaves are blown into the water, but pines and other conifers are free from this objection.

Efficient Methods in Private Reforestation Program

The Nekoosa-Edwards Paper Co., which is carrying on an extensive reforestation program in the state of Wisconsin, has found that good organization and large-scale planting bring down costs, according to F. G. Kilp, chief forester, in a paper presented at the 21st annual convention of the Engineering Society of Wisconsin. In 1928, 470 acres were planted at an average total cost of $5.66 an acre. This is a reduction from $6.51 an acre in 1927 and $11.00 in 1926. On large-scale work, 1928 costs averaged as low as $4.18 an acre.

"We prepare our planting ground," says Mr. Kilp, "by plowing furrows every 6 or 7 ft., the spacing depending entirely upon the amount of natural reproduction growth on the ground. A 10-ton Caterpillar tractor pulling a 24-in. brush-breaking plow is used for plowing the ground. The furrows are plowed as shallow as possible, depending entirely upon the underbrush growing on the area to be planted. In general, the depth of furrows is from 3 to 4 in. Oak brush from 1 to 4 in. in diameter has no effect on the plowing or equipment. Between the plowing and crushing effect of the tractor on the brush, from 25 to 40 per cent of the natural competition is removed to assist the seedlings in getting a good start after being planted in the field.

"Experience has taught us that by starting to plow from one corner of a 40-acre section and continuing around and around until the center is reached, our plowing costs are reduced. The former method was to plow clear across and through on the line each time. The new scheme also increases fire protection for several years hence, since the furrows run lengthwise on each side and parallel from opposite sides to the middle.

"The planting crews usually consist of from seven to twelve men and a foreman. Each man carries his own trees in a light box with the roots packed in moss to keep them from dying out, and a spud for planting. It takes several days to organize a crew properly, or to bring it up to its proper efficiency. After a few days of planting experience each man is expected to plant on an average from 2,200 to 2,400 trees a day. It is back-breaking work and only young, strong backs respond to the strenuous daily exercise. Good supervision means, as a rule, good planting survivals."

The New Water Supply of Sioux Falls

New Type of Wells, Iron Removal Plant and Diesel Pumping Equipment

By F. G. GORDON

Gordon & Bulot, Consulting Engineers, Chicago

THE Sioux Falls, S. Dak., water supply is obtained from shallow wells located in the broad river valley of the Big Sioux River, north of the city. From these wells it is pumped to an iron removal plant, and from the reservoir under the iron removal plant by a second pumping into the distribution system. The pumping equipment at the wells is all motor-driven, while the high service pumps are driven by Diesel engines, with the exception of a motor-driven centrifugal pump used for standby service. There are three elevated tanks and one standpipe located on the distribution system.

The sand and gravel stratum from which the water comes apparently covers a very wide area throughout the river bottom. This stratum lies under a top soil approximately 10 ft. deep, and over a dense clay blanket found at a depth of 35 to 40 ft. below the surface.

The present supply comes from two large circular, open wells, each 50 ft. in diameter, and from five closed wells of a type invented and patented by Mr. Maury, the writer's partner up until the time of his retirement from active practice.

The New Wells.—The design of these wells was made with the idea of securing certain results which could not be obtained with any other type of well in use. It was desired to have a well in which horizontal motor-driven centrifugal pumps could be placed, a well which would prevent any contamination in any way, and a well which would have an enormous strainer area. All of these things have been accomplished in the type of well used.

The lower portion of the well shaft has a strainer area extending completely around the circumference, which permits the water to enter the well. The diameter of each well is 18 ft. In each well there are 4,216 2-in. holes, having a total area of 92 sq. ft. Since these holes are distributed around a circumference of 56 ft., 6 in., there is ample opportunity for water to enter the well without excessive friction loss. In order to prevent sand flowing into the well through these large holes, eight pockets are constructed around the inner circumference. The design is such that concrete columns are located between the pocket, thus providing a rigid cylinder. These pockets are filled with fine gravel on the outside face and very coarse gravel away from that face. The fine gravel next to the outside is held in place during the sinking of the well by a screen which is placed on the inner face of the outside plate. On the inner face of the pockets ½-in. steel plates, punched with 1-in. holes, permit the water to enter the well freely. The width of these pockets from the outer face to the inner face is 2 ft.

Immediately above the strainer section of the well is placed a concrete bulkhead. This serves as a floor on which are located the horizontal motor-driven centrifugal pumps. In some of the wells two pumps have been installed, while in others only one pump has been placed. Each well is constructed, however, with two suction pipes, passing through the concrete bulkhead into the strainer area. A third pipe extends through the bulkhead and is carried up to the level of the floor of the well house. This pipe permits measurements to be taken directly to the water level, and is also used for the installation of a Bristol recording water level gauge.

Seven-day charts are used on this gauge, and these charts provide valuable information. They show for each well the ground water level throughout the year. They also show the drawdown of each well when pumping, and the hours that each well pump is operated.

How the Wells Were Constructed.—The manner of constructing one of these wells is quite simple. The top soil at the location of the well is removed and the steel work for the strainer section erected in this hole. The concrete which forms the cutting edge, and the concrete for the triangular columns located between each of the gravel pockets, is next poured. A clamshell or orange peel bucket is then used to excavate from the interior of the well, and as material is excavated, the well sinks. Sixteen gauge steel plates, bolted together with stove bolts, serve as the outside form for the circular well wall. When enough material has been excavated from the interior of the well so that the well has sunk a distance of 4 or 5 ft., a section of wall of that height is poured, the inner forms removed, and the excavation and sinking continued for another four or five feet, when the operation of pouring another ring of concrete is repeated. This process continues until the cutting edge at the bottom of the well reaches the top of the clay, some 35 or 40 ft. below the surface. Water is encountered some 10 or 12 ft. below the surface and the sand and gravel below this point is, of course, removed in the wet.

The well having been sunk to the clay, the next step is the placing of the concrete bulkhead. The wall of the well is so formed that a shelf or ledge exists at the top of the strainer section. A circular form of the cross-section of the interior of the well is assembled on the ground adjacent to the well. Holes are placed in this form at the proper location for the two suction pipes, and the test pipe. The form is then placed immediately over the top of the well and the two suction pipes and the test pipe are inserted through the holes previously made in the form and are bolted to the form so that they are held rigidly in a perpendicular position.

Each of these pipes has a valve at its upper end, which is in the proper position to be about 12 in. off the bulkhead floor when it has been poured. These valves are closed and are covered with burlap or other material and the form, with the suction pipes and valves, is then lowered through the water until it rests on the ledge immediately above the strainer section. Concrete is now deposited on this form by means of closed buckets. These buckets have a bottom door which can be unlatched to allow the concrete to be emptied when the buckets reach the top of the form. By this method the concrete for the bulkhead is deposited under water up to an elevation six inches lower than the finished bulkhead floor level. During this process the water on the inside and the water on the outside of the well are at the same elevation.

The next step in the process is to place a layer of grout on top of the already deposited concrete. While this is being done, the water level on the interior of the well is carried at an elevation higher than the ground water level outside of the well. This difference in hydrostatic head forces the grout into the concrete and insures a water-tight floor. In the five wells of this type which have been constructed for Sioux Falls, no trouble has been experienced in any of these wells in making the floor water-tight.

After the concrete and grout have set up, the water on the inside of the well is pumped out, thus leaving a dry pump pit. The pumps, together with their discharge piping, are then installed, the valves on the suctions are opened, and the pumping equipment is ready for operation. Since the static ground water level is higher at all times than the elevation of the top of the pump casings, these pumps are primed at all times. All of the well pumps are operated from the main pumping station.

Pumps Installed in Rafts.—Rather interesting installations have been

made in Wells 3 and 4. These are the two large circular wells previously described. When first installed each was equipped with a vertical motor-driven deep well pump. The lack of high efficiency of the vertical pumps and the need for an emergency unit for each well suggested the possibility of placing in each well a horizontal motor-driven centrifugal pump on a raft. Rafts were constructed, each consisting of a wooden platform mounted on steel oil barrels. An I-beam was bolted vertically to the interior wall of the well and a yoke, with rollers, was fastened to the raft in such a manner that with a raising or lowering of the water level in the well the rollers move up and down on the inner faces of the outstanding flange of this I-beam. Flexible hose connections are installed from the discharge of the pump to the pipe leading from the well to the iron removal plant. These installations have been in service for twelve years and have required very little attention, outside of an occasional renewal of the hose.

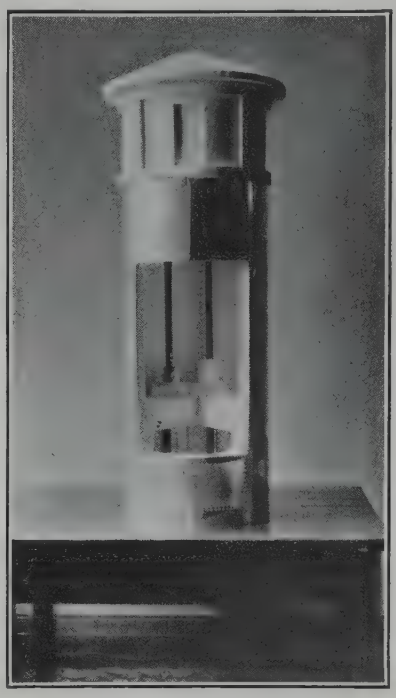
The Iron Removal Plant.—Strict economy dictated the use of several of the more unusual features in the 8-m.g.d. iron removal plant, built at a cost of $11,125 per million gallon capacity. Small filter units permitted hand operation of the valves. Recording water level gauges on the filter effluent line replace the ordinary integrating loss of head gauges. A spent wash water storage sump spreads out the discharge so that a smaller drain answers. The underdrains consist of a steel plate false bottom, into which nozzles are screwed.

Before preparing final plans, an experimental plant was operated to determine whether aeration, followed by sedimentation and filtration but without the use of chemicals, would remove the iron satisfactorily. As the results with the experimental plant indicated a 96 per cent removal, it was decided to employ this process in the contemplated plant.

Rate Controller and Gauges.—A new type of rate controller manufactured by the International Filter Company was used in this installation. This controller is of the Venturi type, with a butterfly valve operated by a diaphragm. Tests, in which the head on the inlet side was varied from 2.5 to 5 lb. in an interval of one minute, showed a variation in discharge of less than 5 per cent.

Recording water level gauges were used for loss of head gauges. The gauges for adjoining filters were mounted back to back on 1-inch gauge boards located on the operating floor. Although this type of gauge is not differential in its action, it gives a satisfactory record because the water level in the filters is carried within a few inches of the same elevation at all times.

Since a single wash water pump is provided, for emergency use a connection is made to one of the high service mains leading from the pumping station to the distribution system. The friction loss through this connection was carefully calculated, and the size of the pipe selected so that the wash water pressure when delivering a sufficient quantity for washing purposes would not be excessive.



Model Showing Construction of Well

A sump having a capacity of 40,000 gal. was constructed to receive the wash water from the filters. The construction of this sump permitted the use of a 10-in. cast-iron drain from the sump to the nearest city sewer instead of the 16-in. drain which would have been required if the sump had not been built. The saving due to the use of the smaller drain amounted to $5,887, while the cost of the sump was only $1,617. Cast-iron construction for the drain was necessary because of its proximity to the gravel stratum from which the water supply is obtained.

The office, laboratory and pump room are located at the front of the filter plant building. The pumping equipment, which is all motor-driven, consists of a wash water pump, three auxiliary low-lift pumps, which can be used as boosters to assist the well pumps during the periods of low ground water, and one high-service pump.

Clear Water Reservoir.—Beneath the iron removal plant is located a clear water reservoir, built several years prior to the construction of the iron removal plant. This reservoir is 116 ft. square and has a capacity of 1,200,000 gal. The construction is of interest in that the floor of the reservoir is composed of a series of inverted groined arches. At the time this reservoir was built the ground water level was some 4 or 5 ft. higher than the bottom of the reservoir and the design was influenced by this fact. The city guaranteed to keep this ground water level down during the construction of the reservoir and was thus able to secure much lower bids than would have been the case had contractors bidding on the work given consideration to this contingency.

The city had four 10-in. wells sunk, one at each corner of the reservoir and connected these wells to a suction pipe leading to one of its high service pumps. By operating this pump during the period of construction, no difficulty was experienced in keeping the ground water level safely below the bottom of the excavation for the reservoir.

After the reservoir had been completed, the four wells were capped with check valves opening in to the reservoir, thus permitting water to flow into the structure whenever the water level on the interior was lower than the ground water level on the outside.

Diesel Engine-Driven Pumps. — In 1915 the city decided to install Diesel engine-driven pumping equipment for regular service, and to relegate its steam-driven pumps to standby or emergency service. Two Busch-Sulzer engines, each of 160 H. P., were selected to drive Aldrich triplex pumps, each having a capacity of 1,600 gal. per minute against 190 ft. head. On each engine shaft was mounted a generator of 135 KVA capacity. A friction clutch installed between the generator and pump permitted the pump to be cut off from the engine and the generator operated as required. These Diesel engine-driven triplex pumps have been in service continuously since their installation and have been entirely satisfactory. In 1926 the city added to its Diesel engine equipment by installing a 400 H. P. McIntosh & Seymour engine, with a 270 Kw. generator mounted on the engine shaft and driving a horizontal Worthington pump through a friction clutch. All of the Diesel engines are of the four-cycle air injection type. Fuel oil is supplied from small tanks overhead which are in turn filled from large steel storage tanks located at the south end of the station building. Cooling water is from the city mains.

Acknowledgment—The above is an abstract of a paper presented before the Missouri Valley Section of the American Water Works Association.

Water Works and Sewers in Illinois.—Of the 1,113 cities, villages and inporated towns in Illinois 508 have public water supplies, and 411 have some form of public sewer system. Of the 411 sewer systems 154 were installed as combined storm and sanitary sewers, 142 as separate sanitary sewers and 115 as mixed systems of sewers and drain tiles.

Always Ready to Pump

Priming and Foot Valves are Abolished with this 100% SELF-PRIMING Line of Centrifugals

All advantages of other types... plus 3 times their capacity! Lift of 27 ft....5 to 10 ft. more than ordinary centrifugals! Muddy water won't clog it! Absolutely automatic...maintains continuous high vacuum! Primer *increases* lift and volume! Simplest vacuum pump ever designed...just *one* moving part! All working parts run in oil bath! Sizes for biggest and smallest jobs... with gasoline or electric motors.

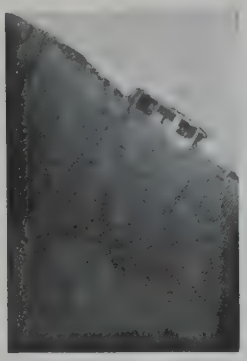
A Trip with our Editor

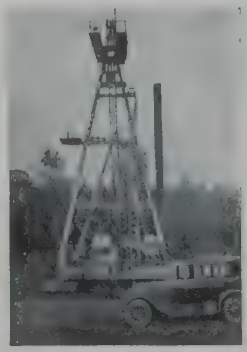


Levee banks make steep going!

Cutting of river bank at end of revetment.

Cypress stumps on right of way. Impassable in car.

Revetment sinking plant.



First tower machine built by the government.

Down the Mississippi wherever levee work is going on, there went the editor. From sun-up to sun-down, driving his car thru places where only tractors should go. Across soft borrow pits; thru cotton fields and sometimes tipped sideways on the slopes of levees, performing stunts which no self-respecting city car should be expected to attempt, on and on he went determined to see as much as possible of work accomplished, and watch government and contract outfits "on the job."

The new program which the government has undertaken involves about $300,000,000. Pictures of this work and graphic descriptions, told by an engineer who understands the nature of it, will make interesting articles for the readers of the Gillette engineering publications, for whose information Mr. V. J. Brown, associate editor, made this journey.

The first article will appear in the November issue of *Engineering and Contracting*.

The same care and thought that are given to this series of articles for *Engineering and Contracting* are given to all editorial material presented to the readers of both *Roads and Streets* and *Water Works and Sewerage*. There has been no change in the editorial management or policies since they were established in 1906.

Ever advancing with the progress and development of the times, but intent on leading only where the best interests of the engineering profession are served. This is why technical books and journals so often refer to these publications.

The confidence of the readers in the technical pages is reflected in the confidence they place in the equipment shown in the advertising pages.

Sources of Water Supply in Southern California

Rainfall—Effect of Altitude on Rainfall—Rainfall Cycles—Disposal of Rainfall—Mountain Runoff —Water Supply from Rainfall on the Valley Floor—Ground Water Basins

By A. L. SONDEREGGER
Consulting Engineer, Los Angeles, Calif.

IT is a matter of general comment among the population of Southern California that of late years we have passed through a period of draught. We have had one dry year after another; in fact, since the great floods of 1914 and 1916, we have had only three years of abnormal rainfall, while the other seven years have been dry. Yet we keep on pumping cheerfully from seemingly unlimited underground sources and nobody appears to worry very much except the superintendent of the water works.

The assertion is sometimes advanced that there are mysterious underground streams, or rivers, which convey water from the Mojave Desert to the Coastal Plain, or from as far distant sources as the Colorado River. There are no indications, or facts, in support of any such contentions. The mountain ranges which separate us from the desert are plutonic in origin. They are many miles in thickness and there are no passages, or cavities, to permit either a flow or a percolation of water across them.

Rainfall.—The water supply of any region in Southern California depends entirely upon the rain falling on its contributary watershed and a study of rainfall phenomena will, therefore disclose the basic factors affecting our water supply.

The major storms which drift from the Pacific Ocean over Southern and Central California are the result of areas of low barometer, usually moving from northwest to southeast. These storms are the most frequent bearers of our rainfall. They are general over the whole region and, as a rule, of fairly uniform relative intensity. The records of seasonal precipitation of any station thus are an index for a broad area.

Effect of Altitude on Rainfall.—The moisture-laden storm winds strike the coast from the southeast, south and southwest. On encountering the mountains along the coast and in the interior, they are forced to rise to higher altitudes, where they are cooled and precipitate a larger portion of their moisture. Thus with increasing altitude, we find correspondingly larger precipitation up to about 6,000 ft., above which there is a slight decrease. This process of absorption of moisture is so effective that after passing the succession of ranges which parallel the coast, there is little moisture left beyond the High Sierras, and the country to the east thereof is naturally barren. This phenomenon is illustrated on Plate 1, which represents a profile transverse to the major axis of the state, from the Coast of San Luis Obispo easterly across the Santa Lucia Range to the San Joaquin Valley and thence over the High Sierras to Owens Valley and Death Valley. This is also illustrated on the same plate by a profile from the coast at Long Beach across the southern Coastal Plain and San Gabriel Valley, passing Mt. Wilson of the Sierra Madre Range and on down to Palmdale in the Mojave Desert.

Rainfall-Cycles.—The rainfall of Southern California is characterized by extreme irregularity, not only from day to day, or month to month of a rainy season, but also from year to year. Yet, while there is an apparent irregularity of seasonal rainfall, it has, nevertheless, been established that within broad limits the fluctuations over long periods of years follow fairly well-defined laws, it being apparent that there are periods of wet years followed by dry periods. The duration of a complete cycle, consisting of a wet and a dry period, is 20 to 24 years; 10 to 12 years in which the average rainfall is above normal, followed by a like period in which it falls below normal.

This phenomenon naturally affects the water supply of the country to the extent that the fundamental problem with which the water supply engineer is confronted, is that of regulating an erratic supply.

Over long periods of years, the consumption of water, through plant growth, corresponds to the average rain. During a series of wet years, with precipitation above normal, there will, therefore, be an accumulation of the surplus water reflected in heavier and deeper saturation of soils, larger stream-flow and rising groundwater levels. An occasional dry year in a wet period will only temporarily check the increase. On the other hand, a dry period will cause the gradual depletion of the water supply. This phenomenon is illustrated in Plate 2, Figs. 1 and 2, which graphically show the seasonal rainfall at Los Angeles and the runoff of the San Gabriel River at Azusa for the years 1871 to 1924.

Fig. 3 of the same plate shows the Mass Diagram, sometimes called "Residual Mass Curve" of the rainfall for Los Angeles, platted so as to show the accumulative effect of the departure from the normal rainfall for the 53-year term. A rising line indicates a rainfall for a season above normal, and a falling line, a shortage. The general downward slope of the dash-and-dotted line denotes shortage over a period of years and consequently a gradual draft on the accumulated water supply, while ascent of the dash-and-dotted line indicates gradual storage of the surplus.

The mass curve then represents what would be the fluctuation of the water level in a tank exposed to the rainfall, from which annually the average amount of precipitation for the 53-year term, namely 15.01 in., is extracted.

A similar illustration is presented in Fig. 4 relating to the seasonal runoff of the San Gabriel River. The mass curve here presents again the fluctuation of the water surface of a reservoir in which the entire runoff would be impounded, with annual abstractions equivalent to the mean recharge for the 53-year term, namely 135,800 acre feet. It should be noted that seasonal fluctuations of stream-flow are much more erratic than those of rainfall. The periods of depletion and accumulation are clearly indicated as follows:

	1871-83 Dry	1883-93 Wet	1893-1904 Dry	1904-16 Wet	1916-24 Dry
Average Seasonal Rainfall at Los Angeles	13.83 in.	20.32 in.	11.25 in.	16.90 in.	12.47 in.
Average Seasonal Runoff San Gabriel River	97,258	224,470	52,427	187,492	120,162
53-Year Mean San Gabriel River 135,800 Acre Feet 100%	138%	89%	72%	165%	39%

The runoff or water supply produced by the San Gabriel River in the driest period of record, 1893-1904, was only 28 per cent of the succeeding wet period. For these two periods, stream gaugings exist for a sufficient number of years to make the results reliable. In order to equalize a water supply like that of the period from 1883 to 1904 to an average of 135,800 acre feet per annum, storage capacity of nearly 1,000,000 acre feet would have to be available, or about four times the capacity of the proposed San Gabriel Reservoir.

Fig. 5, Plate 2, shows the fluctuations of a well at Baldwin Park in San Gabriel Valley for each year. The well responds to the variations in stream-flow and rainfall. The groundwater basin of the San Gabriel Valley is, therefore, comparable to the tank above mentioned, and, as a matter of fact, operates as such. During a wet period

this basin gradually fills with seepage water, both from the streambeds which traverse the valley and from direct percolation of rainfall, so that the water levels in wells keep on rising until this tide turns and the dry period sets in. Inasmuch as it is the function of a reservoir to be drawn down during dry years and to be replenished in wet ones, the lowering of the water-table, as a result of years of drought, does not indicate or prove that the basin is overdrawn. The criterion of an overdraft is the non-return to original levels at the end of a wet period.

The diagrams of Plate 2 show the cyclic fluctuations as determined by observations of rainfall, stream-flow and groundwater levels. In Southern California the water crop of dry periods is supplemented by cyclic underground storage. Dry years are particularly critical for the water users relying upon surface flow. The water supply must be gauged by the dry years crop, and storage is required to regulate the excess flow of wet years. The development of a country based upon the supply of wet periods will sooner or later lead to economic disaster. The present status of the science of astronomy and the related science of meteorology do not permit of periodical weather forecast. Predictions as to our future water supply, therefore, must be based entirely upon records of past performance. Under such conditions, the records of the driest period available, combined with the possibilities of cyclic storage, must be taken into consideration in estimating the available supply, particularly where domestic supply is concerned.

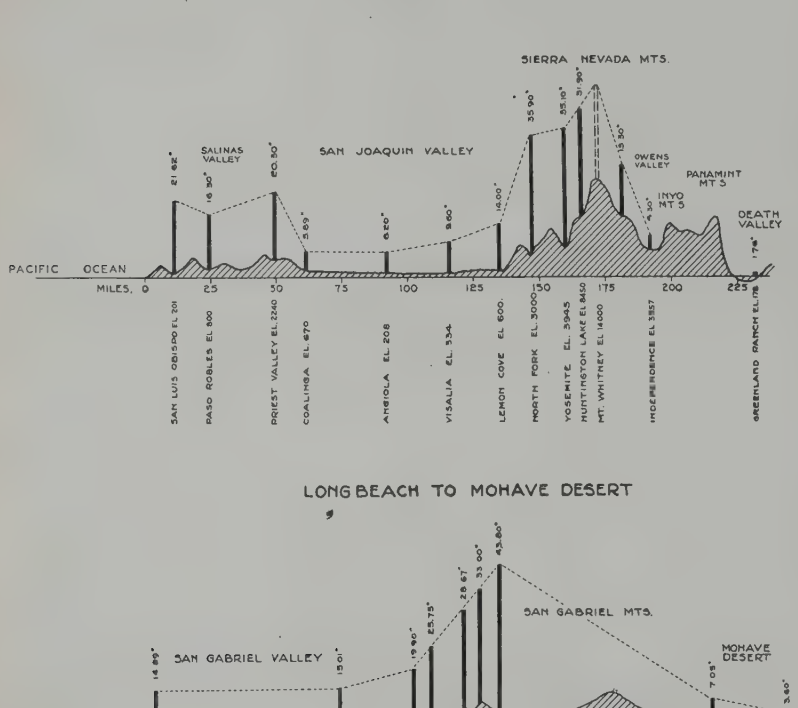

Plate 1—Rainfall Cross Sections Showing Effect of Altitude on Rainfall

Disposal of Rainfall.—Generally speaking, a portion of the rain falling on an area will seep into the ground at the point where it falls; another portion may flow for a distance on the surface or collect into drainage channels, there to seep away unless the storm be heavy enough to produce a runoff on the surface beyond the limits of the watershed, or even as far as tidewater. This "surface runoff," which takes place during a storm or for a few days following, is also termed "storm-runoff."

The rain water which seeps into the ground saturates the soil to various depths, depending upon the magnitude of the storm. This seepage is, in turn, subject first to evaporation from the surface of the ground—second, to a sorption by plant life—and, third, deep percolation beyond the roots plant life and beyond the limits of cap lary action, depending upon soil form tion and moisture conditions. De percolation may subsequently drain to gullies and creeks and thus form t normal flow of a stream which occu between storms and with perenn streams also during the summer. T normal flow of a stream is therefo a seepage-runoff, seeping into t ground first and thence draining the from.

The evaporation and transpirati losses are generally called the "co sumptive use," which is essentially function of the character and type soil and the soil cover.

Rainfall is therefore disposed of "consumptive use," "seepage-runo and "storm-runoff."

This disposal of rain water tak place on the valley floor as well as the mountains, and both types of wat sheds share in the production of water supply.

The relative effect of rainstorms various intensities leads to the conc sion that the largest contributions our water supply are produced storms of great intensity, which la over several days and produce vall rains of 8 in. to 12 in. for the stor Such storms produce a large stor runoff from our mountains. On t other hand, in the valley they are t cause of the deep percolation whi recharges the groundwater basins. study of the effect of individual stor on stream-flow and on the fluctuatio of the groundwater table, will be fou to be very instructive. As a rule, wet winter will produce one storm outstanding intensity, which is respo sible for the greater portion of t watercrop of the season.

Mountain-Runoff.—On a mounta watershed with residual soil cover, see age water may strike bedrock at depth of 1 to 12 ft., or more, there be diverted downhill (see Figs. 3 a 4 of Plate 3). On its downhill cou this percolating water has to run t gauntlet of absorption by the roots trees, brush and herbs which may ha penetrated fissures to depths of 20 30 ft. Abstraction therefore is e tremely active until the percolati water reaches the streambed. Desp this continued tapping, however, see age runoff is produced in dry yea although this may, in part, be due over-year storage and partly to abso tion in talus slides which, owing their unstable and porous formati readily admit the rain water.

The runoff of a mountain watersh is, as a rule, measured at the mou of canyons and includes both the see age, or normal, runoff and the stor runoff. It is the runoff that becom available for water supply. Measu ments of flow on the major streams a made by the U. S. Geological Surv

and the results published in its water supply papers. The runoff figures of the San Gabriel River used in the preparation of Figs. 2 and 4 of Plate 2, were obtained from the water supply papers of the U. S. G. S.

The consumptive use of a mountain watershed for a 12 months season is obtained from the equation

Consumptive Use=Seasonal Rainfall —Runoff.

A study of the daily discharge of a stream and its hydrograph will readily permit the segregation into seepage and storm-runoff, since the latter is characterized by the violent and erratic departures from the more or less uniform normal flow.

For the mountain watersheds it has been found that the consumptive use of the brush or timber cover varies from 20 to 30 in., and that this is, roughly speaking, two-thirds of the rainfall or total water supply. Of the remaining one-third, by far the larger portion is normal or seepage-runoff and only a small part is storm-runoff, except in years of heavy floods. The San Gabriel River, with a watershed of 222 square miles above Azusa, has an average seasonal runoff at that point of 135,800 acre feet, or 600 acre feet per square mile, equivalent to a depth of water spread over the watershed of 11.3 in. The average rainfall on this watershed may be estimated at 31 to 36 in., or about three times the average runoff. For smaller watersheds and lower altitudes, the consumptive use is a still larger percentage of the rainfall and the runoff correspondingly smaller.

The fluctuations of runoff of individual years are even more erratic than the periodical fluctuations. The minimum seasonal runoff of the San Gabriel River occurred in 1898-99 with 9,630 acre feet, equivalent to a depth of water over the whole watershed of less than 1 in., and the maximum in the season of 1921-22, with 410,000 acre feet.

Water Supply from Rainfall on the Valley Floor.—Seepage water penetrating intermittently below the limits of evapo-transpiration activity must ultimately cause the wetting to field capacity (or water capacity), either of the entire formation overlying the water-table, or of well-defined ducts reaching from the surface to the water-table. If there is additional seepage from above, there must be a corresponding addition to the water-table.

The alluvial deposits of which the fill of our valleys is made up are essentially heterogeneous in formation, consisting of irregular bodies of sand, gravel and clay, so that the percolating fluid will naturally find lines of least resistance, to the effect that a uniform saturation over large areas and to great depths is not likely to occur, but rather, the formation of more or less defined ducts.

At points where percolating water strikes an impervious stratum, downward movement is interrupted and a suspended water-table formed. Gradually, lateral percolation is then established and a circuitous route for the percolating fluid is formed until another pervious deposit again permits of more or less vertical movement. Whenever a suspended water-table has been formed, the drainage from same will occur over the edges of the impervious stratum and is likely to collect into trickling streams, as illustrated in Fig. 1, Plate 3. These conclusions are supported by the fact that during the process of excavating shafts in alluvial fills, it is quite common to strike dry materials alternating with moist materials and occasional streams of water.

Inasmuch as alluvial deposits almost invariably show an alternation of pervious and impervious strata, the phenomenon indicated in Fig. 1 is probably the one most commonly encountered. Under such conditions, only a portion of the alluvial mass between the surface and the groundwater table will be saturated.

The recharge of the groundwater may be hastened or delayed by impervious strata. Large clay bodies may not only cause a regulation of an irregular water supply, but they may also provide storage of a magnitude not appreciated because not readily traced.

Absorption is favored by the wedging

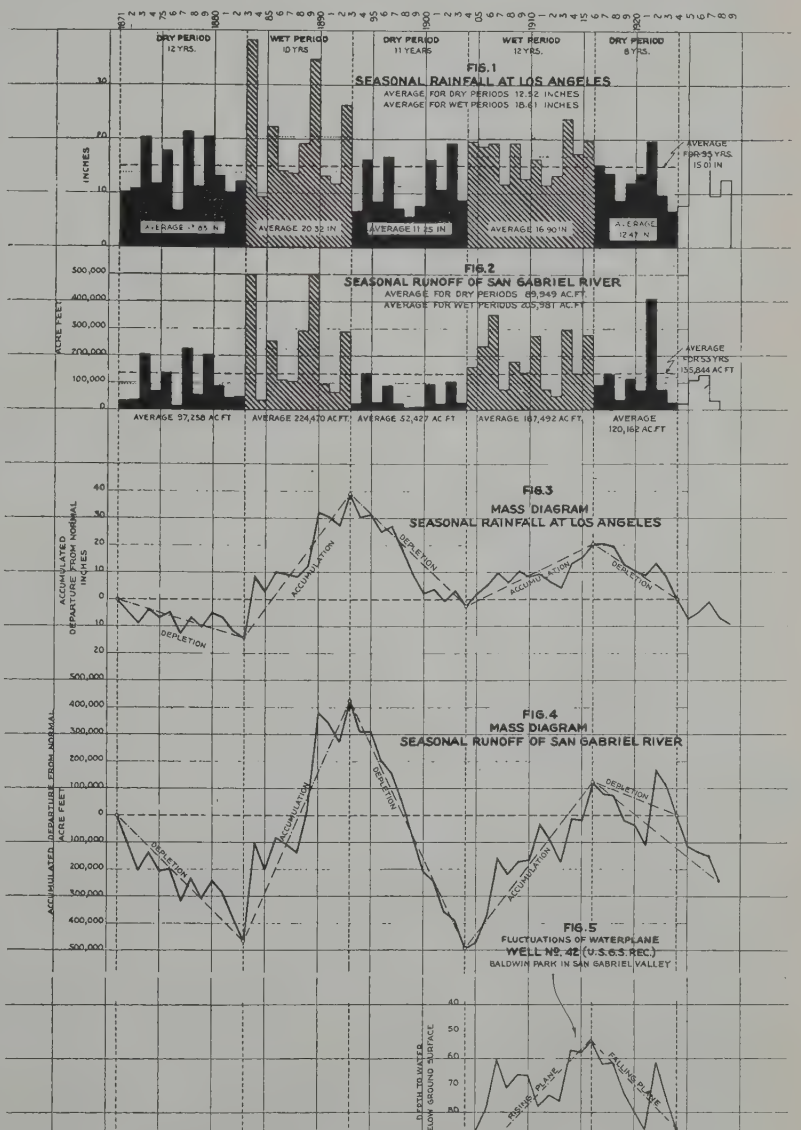

Plate 2—Civic Fluctuations of Water Supply. Averages Computed for Period 1871 to 1924. The Mass Curves of Figs. 3, 4 and 5 Have Been Extended to 1928 to Show the Effect of the Continued Drought

action of roots and especially by decayed roots, the latter having a tendency to drain a saturated mass along defined canals.

The intensity and effect of rainstorms is magnified by the irregularities of topography, whether they are the depth of the root zone, is not likely to occur, with the ultimate result that larger portions of the valley rains reach the water-table than is commonly assumed.

The quantity of the water supply resulting from rainfall on the valley floor

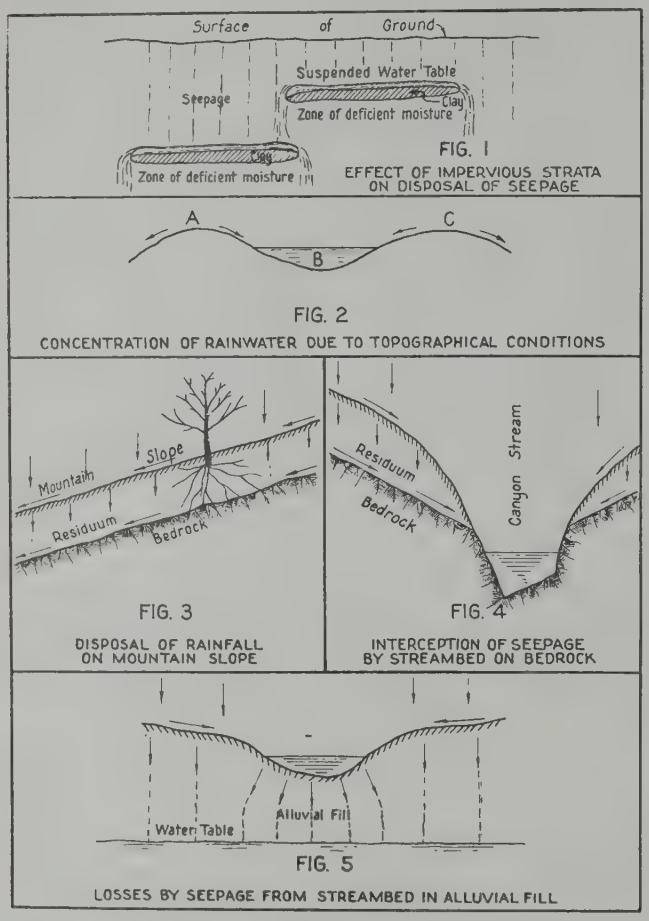

Plate 3

the gentle undulations which occur on an apparently true plane, or hogwallows and hummocky undulations as shown in Fig. 2, Plate 3. It is apparent that some of the rain falling on Points "A" and "C" will flow on the surface to the depression "B." A 3-in. rain may produce at "B" a depth of water of as much as 6 in. and a seepage greatly in excess of that at points "A" and "C." This concentration of rain water, therefore, induces a corresponding concentration of seepage and may be responsible, in part, for deep penetration when the seasonal rainfall uniformly absorbed is not sufficient to satisfy the moisture deficiency and evapotranspiration losses over large areas.

It is therefore concluded that the irregularities of topography, the heterogeneous character of alluvial soils and the actions of roots all tend to concentrate percolation along lines of least resistance and that a uniform wetting of the soil over large areas, even to is not readily ascertained and for this reason has, in the past, often been underestimated. The author has made extensive studies of this phenomenon, and his conclusions have been confirmed by the investigations of the engineers of the U. S. Department of Agriculture and State Department of Engineering.

In the San Bernardino Valley, above the lower Santa Ana Canyon, it has been determined that in certain years as much as 40 per cent of the total watercrop tributary to that valley is from rainfall on the valley floor, and that the contributions from this source exceed 200 acre feet per square mile.

It goes without further explanation that the gentle rains and light storms of dry years do not produce deep penetration to any extent. It is the rainfall of normal, and particularly of wet years with their heavy storms, that causes a substantial recharge of groundwater basins, which can be observed in the response of the water levels in wells. Where clay strata are extensive, this response is lagging, but nevertheless ascertainable. The average proportion of recoverable voids in alluvial materials is about 15 per cent, a rise of the watertable by 1 ft. over an area of 1 square mile would indicate a recharge of 96 acre feet, equivalent to a depth of 1.8 surface inches of water.

Groundwater Basins.—Even the casual observer will notice that Southern California is dotted with thousands of wells, operated by pumping plants. Probably 75 per cent of the water supply of this country is derived from underground sources. The drilling of great numbers of wells has disclosed that the principal valleys, from the San Luis Rey River northerly to the Sierra Madre Mountains, are underlain by deep basins filled with alluvial materials. Having been laid down by flowing streams, these deposits are arranged irregularly, with kidneys of clay interlaced with lenses of gravel or sand. The latter are the water-bearing gravels, which, under favorable conditions, may carry as much as one-third of voids, or interstices, which are filled with water; this water, in turn, being subject to abstraction by means of wells and pumps. The valleys, or basins, are shown on Plate 4.

The entire San Fernando Valley is underlain by such a basin, as is the San Gabriel Valley, the Coastal Plain from Santa Monica down to Newport, the San Bernardino Valley, San Jacinto Valley, etc. The storage capacity of these basins is so enormous that the capacity of surface reservoirs, even of the size of the San Gabriel Canyon Reservoir, is but a fraction thereof. The recharge of these basins is effected by seepage from streams which cross the valleys, and from rain water seeping into the ground of the valley floor and beyond the roots of plant life, ultimately to reach the water-table. The groundwater, sometimes called the "underflow," percolates, as a rule, in the general direction of the surface stream. The rate of percolation is generally slow, ranging from 1 to 3 or 4 miles per year. Unless intercepted by barriers, the underflow will, in its natural course, reach the ocean underground.

A characteristic of most of these basins is the occurrence of underground barriers (dikes) or of lateral constrictions, or both, which interrupt the percolation of the groundwater streams. Taking, for example, the San Fernando Valley. At Van Nuys the valley has a width of 8 miles and a depth to bedrock of 1,000 ft. or more. At its outlet the valley is constricted from Burbank to Elysian Park by the approach from either side of the hill formation, narrowing the valley down to a width of ¾ mile. This is the Elysian Park "Narrows." There is, furthermore, an underground sandstone barrier which crosses the narrows at a depth of less than 200 ft. below the surface. The

combined effect of lateral constriction and barrier is to force the groundwater to the surface and to form the rising stream of the Los Angeles River. This river begins as a small stream in the vicinity of Van Nuys and gradually increases on its course toward the Narrows to a flow of 40 to 50 sec. ft., even in the summer months of a dry period. The Los Angeles River is therefore strictly a groundwater stream (except for its flood flow). In order to prevent pollution, the river is now drained by infiltration pipe lines, from whence it is conveyed to the city.

San Gabriel Valley extends from Pasadena to San Dimas, a distance of some 20 miles, and has a depth of alluvial fill of over 1,000 ft. At the Whittier Narrows the valley is constricted to a width of about two miles. The depth of fill at this point is about 480 ft. The effect of the "narrows" is a stream of rising water, beginning about at the Foothill Blvd. with a small stream and increasing, as the Mission St. bridge is approached, to a river carrying 60 to 120 sec. ft. This supply is diverted in a number of irrigation ditches.

The many narrows constricting our valleys, or basins, are indicated on Plate 4.

In the groundwater basins water will remain pure and potable for indefinite periods and is available for abstraction over long periods as it percolates from the mountains to the sea.

These groundwater basins present a natural and practical solution for the regulation of the otherwise erratic water supply of Southern California, making it possible to store water from a wet period into a dry period; in other words, permitting of a cyclic regulation of water supply. For this reason they are the fundamental physical factor which made possible the development of this country.

Too much emphasis cannot be placed on the economic importance of the deep gravel beds which underlie our valleys. The layman is inclined to lay stress on surface storage, believing that the water problem can be solved by the construction of surface reservoirs. The proper function of our flood control and conservation reservoirs is that of detaining floods. From such temporary storage and flood-waters may conveniently be carried on to the gravel deposits below the mouths of canyons and there caused to sink into the ground, to become a portion of the groundwater underlying our valleys. This method of conservation is also known as the spreading of flood-waters and is now practiced on practically all rivers and streams of Southern California.

Mr. William Mulholland, who might appropriately be called "The Father of Southern California Water Supply," many years ago realized the value of groundwater storage. When planning the Owens River Aqueduct, Mr. Mulholland took advantage of the underground possibilities of San Fernando Valley. In order to dispose of surplus aqueduct water, an irrigation system was planned for this valley and about 60,000 acres are now irrigated from this source. The seepage, or return water, from this irrigation, which reaches the groundwater basin underlying the valley, is estimated at about 25 per cent of the water applied. As a result of 10 to 12 years of irrigation, the groundwater levels in San Fernando Valley have risen in the face of a series of dry years and the flow of the Los Angeles River, which, at the end of a dry period as exists today, would flow from 40 to 50 sec. ft. at the Narrows, now discharges over 80 sec. ft., all of which is rising groundwater. This water is diverted by gravity for domestic use in Los Angeles. Thus a natural process, ingenious in its simplicity, has deliberately been taken advantage of and a gravity supply recovered at the gates of the city, which is conservatively estimated to be worth $3,000 per miner's inch, or, in round figures, $5,000,000.

Literature on Local Water Supply

Water Supply Papers of the U. S. G. S. by W. G. Mendenhall.

No. 137—Development of Underground Waters—Eastern Coastal Plain, Southern California.

No. 138—Development of Underground Waters—Central Coastal Plain, Southern California.

No. 139—Development of Underground Waters—Western Coastal Plain, Southern California.

No. 219—Groundwater and Irrigation Enterprises in the Foothill Belt of Southern California.

These papers, although written about 25 years ago, are still considered as presenting by far the best studies on Southern California groundwaters and are recommended to those interested in the subject.

Bulletin No. 5—Flow in California Streams. By State Department of Engineering, giving records of rainfall and stream runoff and estimated water supply of the State of California.

Bulletin No. 6—San Gabriel Investigations of State Department of Engineering, by Harold Conkling.

Proceedings, American Society of Civil Engineers, May, 1929.

Water Supply from Rainfall on Valley Floor, by A. L. Sonderegger, refers to Southern California conditions.

Acknowledgment.—The foregoing is a paper presented before the Water Supply Section at the 1929 Short Course in School of Citizenship and Public Administration held June 17-21, at the University of Southern California, Los Angeles.

Ohio Sewage Treatment Conference

The third annual Ohio Conference on Sewage Treatment was held Oct. 22 and 23 at Canton, O., with a registered attendance of 105. Two half-day sessions were held, with Charles C. Hommon, of Canton, presiding.

Subjects discussed were: The Canton Sewage Treatment Works, the Salem Sewage Treatment Works, the Ohio Sewer Rental Law, Sewage Disposal Litigation, Operating Small Sewage Treatment Works, and the Biological Oxygen Demand Test. Excellent motion pictures of the Salem Plant were presented.

Officers elected for the ensuing year were: Floyd G. Browne, Marion, chairman; T. C. Schaetzle, Akron, vice chairman; M. W. Tatlock, Dayton, secretary-treasurer; O. F. Schoepfle, Sandusky, member-at-large of the Executive Committee.
mittee.

A cordial invitation was received from Dayton to hold the 1930 conference in that city.

The Dewatering of Fine Screenings

Practice at Various Sewage Disposal Plants in Dewatering Screenings by Pressing and by Centrifuging

By KENNETH ALLEN

Sanitary Engineer, Board of Estimate and Apportionment, New York City

DISPOSAL of sewage screenings is not often a difficult problem in the case of a small installation and where there is land available where they can be buried in trenches, plowed under or merely covered, to prevent odors, fly breeding, etc.; but as the volume increases and land becomes more restricted it presents difficulties that may be very perplexing.

Character and Amount of Screenings.—The character and the amount of screenings per million gallons of sewage naturally varies between wide limits with the character of the sewage and the fineness of the screen. At one plant there will be found a large percentage of paper; at another fecal matter will predominate; at another vegetable kitchen wastes and at another sticks, twigs and leaves, depending on the season. With a normal domestic sewage the screenings will be composed largely of paper and feces, both of which will diminish in amount in stale sewage by disintegration.

In general the fine screenings from normal city sewage usually amount to 15 to 25 cu. ft. per m.g. sewage, weigh 50 to 60 lb. per cu. ft. and contain 75 to 90 per cent water and 80 to 90 per cent volatile matter (dry basis). They are generally so wet as to be "sloppy" but can be handled with a spade.

They are difficult to burn when containing over 70 to 75 per cent moisture and the greater the reduction in this percentage the longer they may be stored without giving off objectionable odors and the more readily is combustion effected.

Methods of Disposal.—Screenings can be disposed of with due regard to sanitation:

(a) By burying in trenches prepared in advance.

(b) By mixing and disposing of with the city garbage.

(c) By digesting, spreading and plowing under.

(d) By dewatering and burying, plowing under or burning.

Burying, in the case of all but small plants, is open to the objection that it requires considerable land and manual labor.

Disposal with garbage is often the most practicable method, but where it is to be incinerated the moisture content demands a thorough mixing with sufficient added combustible rubbish.

Digested screenings are relatively inoffensive, and although containing perhaps 95 per cent moisture, may be disposed of by drying on beds to about 70 per cent moisture, by spreading on the land and plowing under or merely used as fill.

At the Milwaukee works experiments in digesting screenings have been carried on for over a year and others, on screenings from Plainfield, have been made by Dr. Rudolfs at the New Jersey State Agricultural Experiment Station, both with the possibility of success if carried out under proper control. Careful, competent supervision appears to be necessary to bring about active and inoffensive decomposition, involving the proper seeding, temperature and pH control. Moreover, suitable provision for final disposal by drying or otherwise, involving additional land, must be made and in a built-up section this may not be practical. For these reasons some method of rapid preliminary dewatering to not over 70 per cent moisture seems desirable in the majority of cases. There are two general methods of accomplishing this: (1) by pressing, and (2) by centrifuging.

Methods of Dewatering. — Coarse screenings from racks, cages, etc., have been pressed at a number of plants for a good many years. The presses have usually been of the "cider" type, operated by hand or by hydraulic power.

At Washington a hydraulic press of this type, 24 in. in diameter, was installed in 1906, operating under a pressure of 105 to 115 lb. per sq. in., requiring two men for each 8-hour shift. It is understood that this press has stood up well under service and given good satisfaction. In the fiscal year, ending June 30, 1929, 1,905,839 lb. screenings were pressed, varying from 4,153 to 7,974 lb. and averaging 5,221 lb. per day, the weights being of the dewatered material, which contained about 85 per cent moisture.

Favorable results were secured at Washington where coarse screenings were put through a hydraulic press and then burned in a small Decarie incinerator used as a hot water heater for the building. Their volume was reduced about 60 per cent in the press. About three pressings were made per hour during dry weather conditions of flow, when the weight of pressed screenings per 24 hours varied from 2,800 to 3,100 lb. About 200 lb. coal was required to start the fire at the beginning of each shift, or 0.2 lb. coal per lb. pressed screenings.

A similar press, but operated by both steam and hydraulic power, was installed at Boston at the Calf Pasture pumping station in 1912. This required the attention of but one man while handling one to four charges per hour. The dewatered material was burned without difficulty. The press here is understood to have proved unsatisfactory.

At the Ward Street pumping station a steam-operated press, 24 in. by 18 in. diameter, has more recently been installed. The screenings, dewatered to 65 per cent to 75 per cent moisture, are burned under the boilers of the plant.* A press of this kind, operated by steam or hydraulic power, will handle about 500 cu. ft. wet screenings per day and cost in the neighborhood of $3,000.

Dewatering Fine Screenings.—There has been little experience as yet in the dewatering of fine screenings. With the larger amount of fine organic material their water content is probably given up somewhat less readily than from coarse screenings but from what has already been accomplished and with the more extensive experience in dewatering sludge the question of dewatering fine screenings may be considered a matter of detail.

Fine screenings have been dewatered for several years by pressing in the Borough of Queens at three plants in the vicinity of Flushing Bay. The screenings are then burned in small oil-burning "incinerites." A test of one of these, located at Corona, was made in 1920. The screenings were placed in the hand press and left to drain for 19 hours when they were removed and burned. The 2.78 cu. ft. pressed screenings contained 69 per cent moisture, weighed 52.0 lb. per cu. ft. and were consumed in three hours with a loss of 93 per cent weight, for which 0.018 gal. of oil was required per pound dewatered screenings. By care in firing these small installations are quite satisfactory.

In 1914 the city of Baltimore installed a 24-in. press similar to that at the Calf Pasture pumping station at Boston. Pressures here were carried as high as 170 lb. per sq. in. Four-and-one-half baskets were charged per hour, requiring the attention of two men. In spite of the pressures used the moisture in the product was too great for easy burning, possibly due to the high rate of operation.

In 1921 three more presses of the same type were installed at the main

*If they are so sloppy as to be forced through the perforations of the basket a small quantity of shavings are added to absorb the excess moisture. Two men are required for operation on each shift.

Sewage Treatment Plant at Oyster Bay, N. Y.

sewage pumping station. Four pressings per hour can be made with these if necessary. By measurement about 3 cu. ft. dewatered screenings were produced from each of 48 pressings per day from a sewage flow of 25 m.g. As these wighed 60 lb. per cu. ft., the total output amounted to about 8,000 lb. per day. To burn this required about 1,600 lb. of coal.

In 1926 C. E. Keefer made tests in pressing the screenings at the Eastern Avenue sewage pumping station.†

Average Results

	Unpressed Screenings	Pressed Screenings
Cubic feet per m.g. sewage	7.75	4.04
Pounds per cu. ft.	60.17	50.03
Per cent moisture	86.45	72.19
Coal used for incineration:		
Lb. per cu. ft. screenings		11.07
Per cent reduction in volume by pressing		47.85

The estimated cost of a pressing and incinerating plant to dispose of the screenings at this station was:

For: Building	$3,540
Incinerator, chimney, etc.	1,800
Press	3,600
Total	$8,940

and the annual cost was:

For: Fixed charges		$ 894
Operation:		
Coal (97 tons)	$626	
Power for press	10	
Removal of ashes	20	
		656
Total		$1,550

As a result of these tests it was decided to continue this method of disposal.

Experiments in pressing screenings were made by Mr. Keefer at the Back River disposal plant, Baltimore, in 1927, using a cider-type press operated by steam under 175 lb. per sq. in. pressure. The press was manufactured by the Coffin Valve Co., and cost, in 1919, $2,785. The screenings averaged 7.75 cu. ft. per m.g. sewage and contained about 86 per cent moisture, which was reduced to 72 per cent, with a reduction of 48 per cent in volume by the operation.

†Proc. Am. Soc. C.S., Sept., 1929. The flow handled at this station averaged 25 m.g.d. in 1925.

Dallas, Texas, installed a 19-in. hydraulic press in 1915. With a pressure of 60 lb. per sq. in., four to eight baskets of screenings were pressed per 24 hours sufficiently to burn readily under a boiler. The only attention required was that of the boiler room helper. The operation of this press is said to have been satisfactory.

At Milwaukee it was attempted to press the fine screenings in a Berrigan press. This proved quite feasible, but was finally abandoned as too costly.

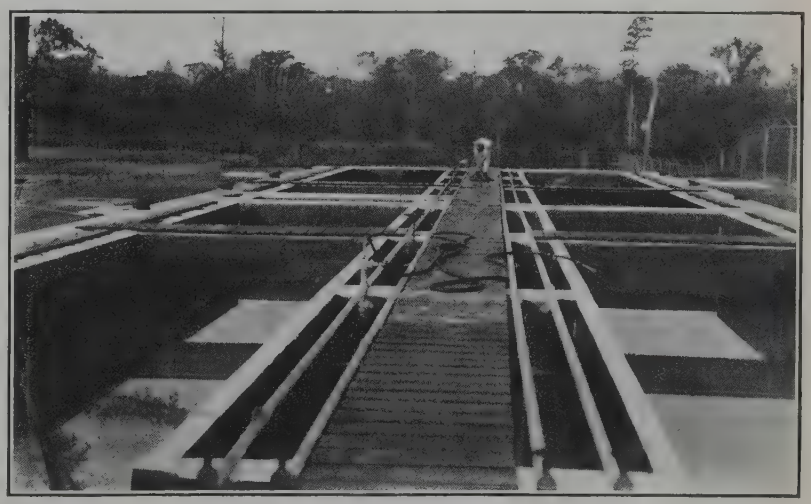
A plant designed by Metcalf & Eddy is now being installed at Dayton, Ohio, in which the screenings from a Dorrco screen with ⅛-in. slots will be dewatered in presses made by the Hydraulic Press Mfg. Co. and then burned in a specially designed incinerator. It is estimated that the moisture content of fine screenings from 26 m.g.d. sewage will be reduced from 85 per cent to 65 per cent by placing them in slotted baskets and compressing under a hydraulic plunger. The 230 cu. ft. dewatered material produced per day will then be burned together with screenings from a 4-in. rack 80 per cent moisture and skimmings 75 per cent moisture.

From the foregoing it is safe to conclude that normal screenings, whether from coarse or fine screens, may be dewatered in a press of proper design to such an extent as to be disposed of by burning under boilers, in a garbage incinerator or in an incinerator specially designed for the purpose, with little additional fuel. At Baltimore the life of a press of the cider type has been found to be about eight years. These are generally of 24-in. or 26-in. diameter, operated under a pressure of 150 lb. per sq. in. and compress the screenings to half their original volume.

Experience with wet screenings has not been so convincing, although these are burned in a few places.

At Miami, Fla., about 40 cu. ft. per day of screenings, averaging 50 lb. per cu. ft., are successfully disposed of by incineration in a Nye odorless incinerator without additional fuel and without odor after pressing under a dead weight of 500 lb. They are stored in covered garbage cans until night, when they are hauled to the incinerator. This is located in a residential section.

The fine screenings at Rye, N. Y., Long Beach, Calif., and coarse screenings at Canton, O., are disposed of without pressing; at Rye in an adjacent Morse-Boulger incinerator with the village garbage, and at Long Beach and Canton in incinerators designed for the plant. At Long Beach 47.7 cu. ft. screenings per day about 80 per cent moisture are successfully burned in a dutch-oven furnace with 21,300 cu. ft. natural gas. At Canton about 27 cu. ft. screenings of similar water content are incinerated daily after an hour's draining in perforated cans, together with an average of about five dead animals, with the use of about ten tons of coal a month. At the Jamaica plant, Borough of Queens, the 5 cu. ft. fine screenings per m.g. from a flow of about 10 m.g.d. of sewage contained 87 per cent mois-



View of Portion of Sewage Disposal Plant at Teaneck, N. J.

ture. The attempt to dispose of these wet screenings with the city refuse in a 150-ton incinerator did not prove satisfactory.

Centrifuging.—There is no reason to suppose that screenings as well as sludge may not be dewatered by centrifuging. The smaller volume of foul drainage liquor would present a less serious problem and it is quite possible that a less expensive type of centrifuge than the Bescoter-Meer might answer the purpose. Very little has been attempted in this line but as the number of screening installations increases it is possible that this method of dewatering may be found practicable.

At Reading, Pa., screenings from a fine-mesh "Weand" screen were placed in canvas bags and dewatered by a centrifugal "hydro-extractor," about 6-in. diameter by 3 ft. 6 in. high, which reduced the moisture in a charge of 500 lb. from 85-90 per cent to 61-73 per cent moisture in eight minutes. Its weight was reduced from 65-70 lb. to 30-35 lb. per cu. ft. by the process, when it contained about 72 per cent volatile matter. It was then burned under the boiler at the plant. The plant was rebuilt some years ago and the screen abandoned.

Experiments were conducted by George G. Gascoigne at Cleveland in which about 1¼ tons of fine screenings, 85 per cent moisture, after a brief period of draining, were placed in burlap bags and dewatered in a "Laundryette" centrifuge. The moisture was reduced to 65 per cent and screenings burned in a small "Kewanee" incinerator by adding about 25 per cent of coal by weight. The incinerator had a nominal capacity of 300 lb. screenings per hour, 90 per cent moisture. Some smoke and odor were given off, but no complaints were recorded.

Screenings were burned under a "Sims" boiler for a while at the Easterly Works several years ago after dewatering in a "Troy" centrifuge, but some odor resulted and the practice has been given up.

At Baltimore tests of a sludge centrifuge made by the Hanomag Co. of Germany indicated that the passages were too small to function properly with screenings.

Centrifuges, belt-driven or direct-connected, are on the market that may prove adapted to service of this nature. They generally consist of a perforated basket, 30-in. to 40-in. in diameter, in which the screenings are placed and which rotates at speeds as high as 900 r.p.m., the drainage liquor being let off by a pipe. To unload, the basket is raised, moved to one side and dumped by rotation on trunnions. In one type there is a counterbalanced "unloader" which, by a slow rotation, scrapes the cake gradually from the top down. The material thus loosened falls through a port in the centre of the bottom, provided with a cone valve, to a conveyor or truck.

The first cost of a 40-in. centrifuge is about the same as that of a press. Operation is largely automatic, requiring but one man, but a fair comparison with presses, which have more often been used, cannot be made at this time.

Conclusions.—Dewatering screenings to an extent when they may be burned without difficulty may be accomplished by pressing and probably by centrifuging. With the increasing number of screening plants and a growing insistence on hygienic conditions this method for their final disposal seems likely to develop in the future.

In conclusion the author desires to acknowledge as the source of much valuable information that he has freely drawn upon in the preparation of this paper, the following gentlemen: Major D. A. Davison, U. S. A., also Robert Cramer, George B. Gascoigne, Charles C. Hommon, J. E. Jewett, F. B. Jones, C. E. Keefer, W. T. Knowlton, F. A. Marston, Langdon Pearse, Asa E. Phillips, W. M. Pratt, Harry L. Shaner, Ralph Van Duyne and W. W. Young. Thanks are also due the several manufacturers of dewatering machinery and incinerators for details concerning their

devices that have been kindly furnished.

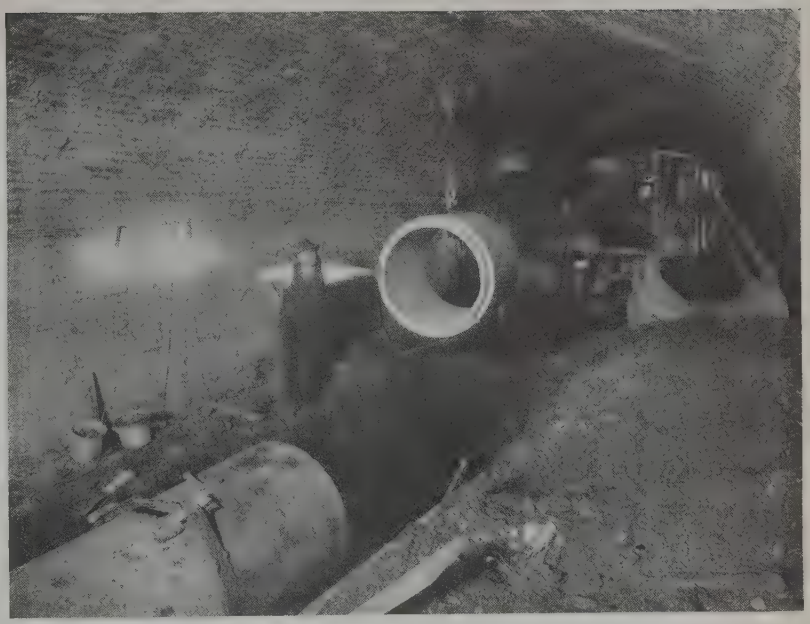
The application of devices for filtering or straining slimes or sludges has not been discussed in this paper, for although some of them may prove valuable for the dewatering of screenings reliable information as to results obtained has not yet been obtained. In one experiment, however, by Filtration Engineers, Inc., screenings conditioned with lime were dewatered from about 90 per cent to 66 per cent moisture on a vacuum filter.

Acknowledgment.—The foregoing paper was presented Oct. 16 at the 35th Annual Convention of the American Society for Municipal Improvements.

Trencher Shovel Digs Sewer in Cramped Quarters

A construction job which afforded more than the ordinary amount of excitement was that recently executed by a crew of Ralph Bucci & Co., Pittsburgh sewer contractors, consisting of digging trench and setting pipe in a shallow, semi-round sewer tunnel under the plant of the Homestead Steel Works, Homestead, Pa. Steaming hot drainage water flows directly into the tunnel from the steel mill.

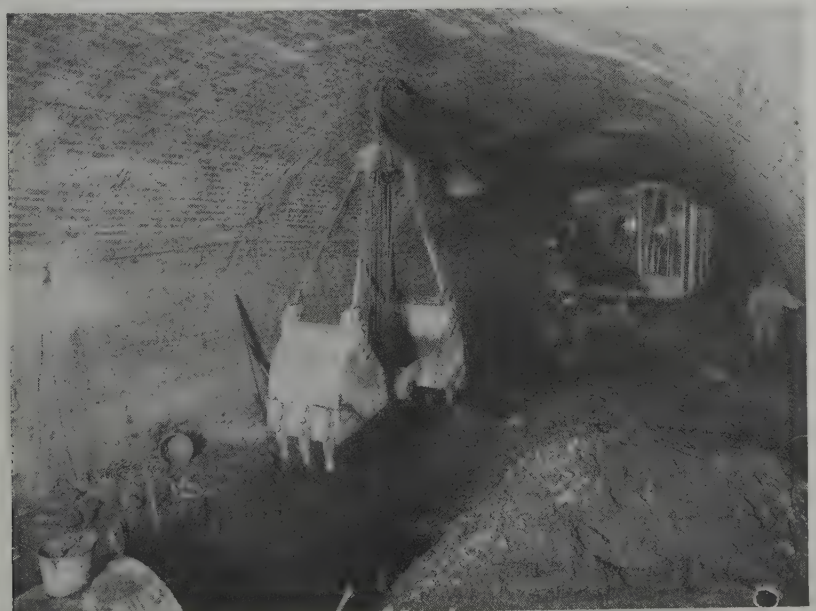
A sanitary sewer of 36-in. reinforced-concrete pipe was laid through the entire length of the 1,000-ft. tunnel. The trench for the pipe was dug to a depth of 4 ft. The contractors took the job after comparing the 13-ft. headroom in the tunnel with the clearance height of their Byers ½-yd. trencher shovel—11 ft. 2 in. It was found that the best way to handle the job was to use the trencher shovel boom, taking off the dipper and arm and substituting a ½-yd. clam-shell bucket. The bucket was replaced with a hairpin hook for pipe setting.



Laying 36-In. Reinforced-Concrete Pipe With Trencher Shovel Under Homestead Steel Works

Under the difficult conditions existing in the tunnel, the shovel was able to dig in excess of 300 cu. yd. a day, it is stated. However, only 80 lin. ft. of trench was excavated at a time; this length of trench was dug and the pipe set in 10 hours. Pipe laying was delayed because all joints in a section had to be sealed with tar and allowed to set before the next section was begun.

The possibility of an added thrill to the workers was introduced when it was learned that the water in the tunnel sometimes rises to a height of 6 ft. during heavy storms. Throughout the work, however, fair weather prevailed, and the members of the crew had nothing more than the normal flow to contend with.



Trenching With Limited Clearance Within Sewer Tunnel Under Steel Plant at Homestead, Pa.

Water Company Spends One Third of Every Revenue Dollar for Taxes

The total amount paid for salaries and wages last year by the Hackensack Water Company, serving fifty-one towns and cities in Bergen and North Hudson Counties, New Jersey, was $1,051,318.65, according to statistics prepared by the company's accounting department.

Taxes for the year amounted to $842,144.02. Of every dollar of revenue, 30½ ct. was paid out for taxes.

More than 50 per cent of the total revenue of the company is paid out in taxes and wages. Practically all of this amount, in addition to expenditures for materials, supplies, maintenance and repairs, is spent in the territory served by the company.

Coal used at New Milford and New Durham cost $100,103. To haul this coal, eleven freight trains of fifty cars each would be required. If placed end to end, the trains would reach over five miles.

The expense of repairing buildings was $22,604. Sufficient money was spent on postage to mail a letter to every man, woman and child in the city of Newark.

More than 1,000 different types and sizes of material are carried in the company's storerooms. During the year more than 3,500 purchase orders and 6,000 voucher checks were drawn. Cards in the company's files showing detailed costs of service installations number over 60,000.

Purchased Power for Pumping Station Operation

By T. R. HUGHES

Mechanical Engineer, American Water Works & Electric Co., New York, N. Y.

WITH the development in the last five years of central station power plants, generating electric energy at high efficiencies, and the increase in reliability of this power, due to the interconnection of the various transmission systems, the advantages of using purchased power for the operation of small pumping stations are becoming more significant. These advantages are being generally realized now. Operation with purchased power means a minimum of investment, a minimum of labor cost and a relatively high operating efficiency for small units. Compensating for these economies the cost of energy is usually somewhat higher than the cost of coal.

Comparison of Operating Costs.—To gain some picture of the size at which the steam plant no longer becomes the most economical for operation, I have plotted a curve in Fig. 1. This shows the total cost of pumping station operation, fuel, operating labor, maintenance and miscellaneous supplies, per water horse-power hour developed compared with the average water horse-power load on the plant. The term "water horse-power" is, of course, the brake horse-power required to drive a pump of 100 per cent efficiency. The cost of pumping per water horse-power hour is a particularly significant figure, both because it is a unit of work and because it may be readily visualized when it is considered that the overall efficiency of the average motor-driven pumping unit is in the neighborhood of 75 per cent. Therefore, one water horse-power hour may be roughly considered as equivalent to 1 kw. h.

The figures shown are all (except No. 14 which represents a carefully prepared estimate) taken from operating records of plants actually in operation and represent results being obtained. The only correction made to them was to reduce coal to $3.50 per ton. They are all fully comparable. The figures represent, with the exception of No. 13, plants operating reciprocating pumps, water being measured by plunger displacement. Actual water measured would be less and cost per water horse-power hour more than shown. With any centrifugal pump where water is metered economy will be correspondingly increased.

In Fig. 1 it will be seen that, with a plant as large as 650 water horse-power, the cost per water horse-power hour is ¾ ct. With a plant of 25 water horse-power average load, the cost of pumping is 4.8 ct. Both of the plants considered are operated more economically by purchased power. There are very few rates for energy at less than 1 ct. per kilowatt hour. To this must be added labor and miscellaneous operating costs. On the other hand with an average load of 25 water horse-power, it is probable that power could be purchased for about 1½ ct. Labor would be less than that required

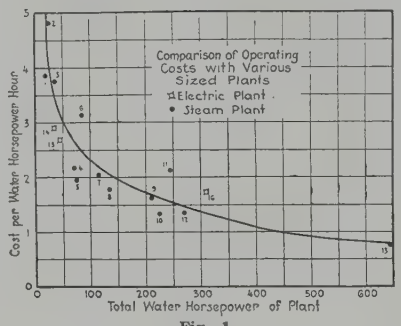


Fig. 1

to operate a steam plant, and it would appear probable that this station could be operated more economically with purchased power. From a point of view of operating cost along, it would seem probable that electricity would prove more economical on the plants smaller than 100 or 200 water horse-power.

Two points are also shown in Fig. 1 which represent the operating cost of plants operated on purchased power. The electric plant of 44 horse-power size, No. 15, is operating more cheaply than the steam plant of that size would. This means that not only is the cost of operation of this plant less than the cost of operation of a steam plant, but also considerable saving has been made in the investment required to build the plant. The 310 h. p. plant, No. 16, operated by purchased power, costs somewhat more to operate than one of equivalent size operated by steam. This, therefore, is approaching the point of demarcation between the economical electric and the economical steam plant.

Comparative Costs for Operation and Fixed Charges.—Figure 2 shows comparative costs for both operation and fixed charges of various types of plants. It is a study of a plant starting with a load of 535 and growing to one with a load of 890 water horse-power; that is, it would be a plant pumping an average of 15 m.g.d. against a head of 203 ft. and would grow to a plant of 25 m.g.d. against a head of 203 ft. In this study steam, Diesel engines and purchased power were all considered. The investment required under each of these heads was very carefully estimated and the operating costs are those which can be achieved. The coal is at $3.50 a ton as was the case in Fig. 1. Diesel engine fuel is at 6 ct. a gallon and electricity 1 ct. per kilowatt hour. Fixed charges on the investment required in each case were taken at 12 per cent for taxes, depreciation and interest. In the upper curve it will be seen that for the smaller plant purchased power is almost as cheap, considering operation and fixed charges, as the Diesel engine plant, even when the load is as great as 535 water horse-power. The lower curve showing operating cost shows that steam is considerably cheaper for each case. The investment in the small steam plant, however, is so large as to throw this out of line and makes the total cost greater than of either electricity or Diesel power. Purchased power is probably the cheapest for plants smaller than 400 h. p. Diesel engines may be the most economical source of power for plants with a load of from about 400 to 600 water horse-power.

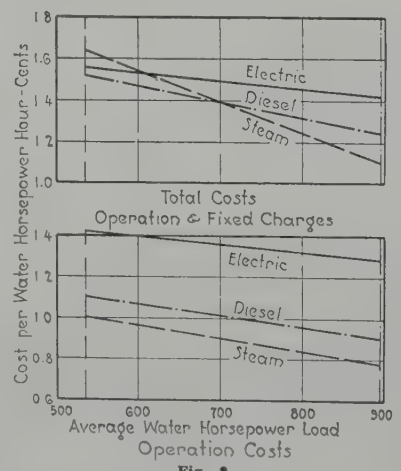

Fig. 2

When Fig. 2 was prepared, it was not realized that, in the case of the particular plant considered, the apparent dividing line between all three types of equipment would be covered. It was merely a coincidence that due to the loads chosen this was the case. The figures, unfortunately, all represent estimates. These curves and generalizations drawn from them are made, not with an idea of laying down any hard and fast rule, and saying to the water works designer that he can always save money, if building a plant whose average load will be 200 water horse-power, by operating it on purchased power, or that he will always save money by building a 400 water horse-power plant and operating it by Diesel engines. The curves can only be used to draw certain general conclusions and point the direction in which the most careful study should be made for plants of various sizes.

The plant studied in Fig. 2 was one which has a relatively high load factor. A plant which has a very low load factor would probably show greater relative economics due to purchased power than the one considered here due to saving banking losses and the like.

Where a plant pumps into a large reservoir with constant load and ample reserve, all the advantages are in favor of purchased energy. In the case of the very small plant with some storage in the system, automatic operation may be used and almost all labor eliminated. In some cases it may prove desirable partially to electrify the plant. Where some existing steam equipment is economical this may be the case, either using the steam for base load or for peaks as may best suit the conditions. The partial electrification of a plant has the double advantage of reducing the cost of duplication of electric power, should it be necessary, to a minimum and also holding a convenient club over the head of the power company to keep them from raising the rates after they think they have secured their customer, since it is always easy to go back to the steam plant if they prove unruly.

The most difficult condition under which purchased power may prove economical is the case of an existing steam operated plant of small size which is to be converted to an electric plant. The only excuse for the electrification is that the total cost of the electrified plant, both for operation and fixed charges on the equipment required for electrification, will be less than the cost of operation of the steam plant. It may be easy to show that the cost of operation of a plant run on purchased power is cheaper than one run on steam power. When, however, we have to pay fixed charges on new equipment out of this saving, it very rapidly evaporates. Although the power companies frequently point out the large savings which may be effected by the electrification, it is frequently difficult to justify this procedure when one must make considerable investment.

The maintaining of a high operating efficiency when the energy cost for the plant is high is important. If a plant is being operated on purchased power, it is highly important that care be taken in the selection of pumping units in order that the efficiency may be as high as possible during normal operation.

Operating Efficiencies.—One installation from which we have very good data on operating results shows that for 12 months the average operating efficiency of unit No. 1 in this plant was 66.7 per cent. Under test conditions and at exactly the right head this unit had an efficiency of slightly more than 70 per cent. It is a constant speed unit and the head varies as much as 10 per cent above and below the average which, of course, cuts into the operating efficiency. Unit No. 2 in this plant had an average efficiency of 72.7 per cent for 12 months with a test efficiency of about 77 per cent. Unit No. 2 is operated by a variable speed motor, and the efficiency, of course, is low at any time at which the motor is run below full speed. These two units pump into a system which has very little storage and, therefore, the pumpage rate has to follow the demand closely and the system is subject to wide variations in load. In spite of the exacting load conditions and with only two units installed, the pumps operated within 6 per cent of their original guarantees. The figures are based on average heads obtained and, therefore, are not absolutely correct.

In another plant at which four units are operated, the average efficiency of the four units on test is 64 per cent. The average operating efficiency for 12 months of these four units is 63.7 per cent. This is a direct system. The four units are relatively small, and all are constant speed units. They are operated close to their point of test efficiency at all times.

A third plant considerably larger than either of these two just spoken of, pumps into rather large reservoirs and the pumpage rate is practically constant from day to day. This plant is operated on purchased power, and the average operating efficiency for 12 months is 83.6 per cent. Tests on the two units operated, both of them variable speed units, give an average efficiency of 82 per cent. The efficiency of 83.6 per cent is hardly reasonable. The variable in measuring average operating efficiency and test efficiency is the head against which the units operate, which varies considerably. The only conclusion that can be drawn from these figures is that the operating efficiencies of these motor driven pumps, which deliver water into a reservoir at a very nearly constant rate, is very near the best test efficiencies of the units. Of the two units in this plant, one has a capacity of 14 and the other a 21 m.g.d. They, therefore, may operate very near to the designed conditions at all times as the one of the most suitable size may be operated all the time.

These last two cases cited illustrate the desirability, when installing several units at a station, of not getting two or three units of the same capacity. A little care in selecting the capacities of the units will result in being able to operate at full load at all times and with consequent high efficiency. When more than one unit is installed, with a change in load, one pump may be readily shut down and another started up and the most suitable unit always kept in operation.

With the interconnection of transmission systems, electric power is quite reliable, but some duplication is usually necessary. Judging by the experience we have had in two particular cases, it would seem probable that the duplication need be for use only for a short time. One plant supplied by a transmission line, 7 miles long, from the nearest sub-station, and that substation supplied by only one high voltage line, 25 or 30 miles long, has been subject to no extended outages. They have a number of times had power off for 15 minutes to an hour.

Another plant supplied by one transmission line, 1 mile long from the nearest sub-station, which does not supply any other consumers, and the substation supplied with power from a single high tension line, 15 to 20 miles long, has suffered from only occasional outages of from 15 to 20 minutes within the last two years. It would seem probable that, in supplying duplication for a plant operated on purchased power, unless the conditions were such as to make interferences likely, an outage of more than two hours would not be likely to occur.

Summary.—Summarizing:

1. We may say that a pumping station operated from purchased power will on operating cost alone be cheaper than with steam for plants whose load is from 100 to 200 water horse-power and below, the advantages of purchased power being greater as the plant becomes smaller.

2. When fixed charges as well as operating costs are considered, purchased power will probably be the cheapest plant to build and operate where the load does not exceed about 400 water horse-power.

3. For operation of a plant with purchased power, care should be taken to select units which will operate very near their peak efficiencies at all times. It is probable that for a direct system the average operating efficiency of the unit may be about 95 per cent of the guaranteed efficiencies provided suitable equipment is installed.

4. Purchased power with the present interconnection of electric systems is quite dependable and except for unusual conditions outages of more than 2 hours should not be expected.

Water Works and Sewerage in Wisconsin.—Figures in 1929 Waterworks, Sewerage and Refuse Code of the State Board of Health of Wisconsin show that 282 municipalities in that state have public water supplies and 211 have public sewerage. Of the latter 127 are not provided with any form of treatment. There are 10 municipalities in the state with less than 500 population (1920 census) that have both water works and sewerage and 29 that have water works only. Over one half the municipalities between 1,000 and 1,500 population have both water works and sewerage and about one quarter have water works only. All cities over 2,000 population except one are equipped with both water works and sewerage.

State Forbids 500 ft. San Gabriel Dam

Report of Consulting Board of Geologists and Engineers on Site for Los Angeles County, Calif., Flood Control Structure

As a result of a report by a consulting board of geologists and engineers, Edward Hyatt, State Engineer of California, has denied the application of the Los Angeles County Flood Control District for authority to construct the San Gabriel dam in the San Gabriel river, 30 miles northeast of Los Angeles, Calif. In the report of the state engineer the consulting board declared that the proposed San Gabriel dam, a gravity concrete structure, 500 ft. high and capable of storing 240,000 acre feet of water, could not be built safely on the foundation existing at "the forks" site. However, the board expresses the opinion that a dam of flexible type, such as an earth and rock fill structure of conservative proportions, could be built safely at "the forks" site.

Disapproval by the state of the application, according to the state engineer, is without prejudice to the right of the county to file any new application for a dam at this or any other site that the county may wish to submit. It means simply that the state finds that a 500-ft. concrete dam if built on the foundations at this location would not be safe and this particular application is disapproved.

The consulting board consisted of Charles P. Berkey, geologist, of Columbia University, New York; George D. Louderback, Geologist at the University of California, Berkeley; Ira A. Williams, Consulting Geologist, Portland, Ore.; G. A. Elliott, Engineer of the Spring Valley Water Co., San Francisco; M. C. Hinderlider, Colorado State Engineer, and J. L. Savage, Chief Designing Engineer of the U. S. Bureau of Reclamation.

The consulting board's report, follows in part:

Each Dam Site a Problem.—The natural conditions in the San Gabriel Mountains are much more complex than is usually appreciated. Although certain general geologic features prevail, each dam site is a problem in itself and demands special study and handling.

The rocks of this site and vicinity are ancient crystalline types, including granitic and dioritic gneisses and occasional schists, all cut by variety of igneous intrusions, including granite, aplite, diorite, dibase, basalt and porphyrites. The result is a crystalline complex, whose detailed history is long and involved, but whose character and quality would be eminently satisfactory for any engineering structure if the rocks had not undergone deformation and decay.

The rock complex is cut through in every direction by faults and slips and crush-zones that have separated the mass into blocks of varied size and shape, most of which are comparatively small and roughly wedge-shaped or lenticular. No portion of this site or immediate adjacent ground is free from this condition. In addition, each individual block formed by these fault movements is internally broken, and mol fractured and jointed, in such manner that most of the material separates readily into small pieces and there are no extensive bodies of solid rock.

Rock in Faulted and Crushed Condition.—The original structural make-up of the rock formation, with its many different types of varying individual resistance to crushing, has favored the development of internal differential movement, and this has resulted in the mashed and jammed appearance that characterizes the rocks of this site. The rock was not originally weak, but was unevenly resistant and the forces producing movement have been powerful enough to overcome the resistance of the whole mass.

It is generally conceded that the San Gabriel Mountain mass has been thrust up, and that in addition to very large movements on the faults along the boundaries of the mountain block, there are a few zones of major movement cutting through it. One of these zones takes an east-west course and has determined the alignment of the east and west branches of San Gabriel river. Another such zone apparently runs nearly north and south and has been followed by the river in its course below the forks. The forks is thus in the junction area of the two fault zones. The unusually numerous fractures at this locality seem to be consistent with this larger structural relation.

In addition to the faulted and crushed condition of the rock, much of it, especially that on the upper slopes of the canyon sides and along the principal movement planes and crush zones, is extensively disintegrated and decayed. The crushed and pulverized rock along the fault breaks is often transformed into clay gouge. Some of it is so soft that when moist it can be molded with the hand.

Unfavorable Controlling Factors.—The surface materials are weathered into soil. By the same process some of the unbroken material beneath is altered or rotted to such condition that it can be broken easily with the fingers. Along the more fractured zones decay extends as deep as explorations have gone. This altered condition, together with the excessively broken character of the ground and the smoothed and lubricated movement planes, are controlling factors with respect to any very large engineering structure.

Observation shows that the crush zones and movement planes and slips occur in all portions of the site, as well as beyond the site proper in every direction. Drilling data prove that the same kinds of weaknesses, especially the slips and faults and broken rock and gouge, extend also beneath the site to as deep as explorations have gone.

Landslides are common on the canyon slopes. These doubtless represent the slumping of individual blocks or groups of blocks, separated from each other by slip planes, when they are weakened by progressive undercutting of a stream, lubrication due to access of water and downward extent of weathering. Relatively recent slides have occurred at the site and at several places in the vicinity.

Where the rock is harder or more uniform than the average, the individual fault blocks are larger, the internal slips and crushes are less numerous and the accompanying decay correspondingly less extensive. This is the reason for the less broken appearance of the east abutment than that of the west abutment, although there are no different kinds of effects or any other principles represented.

Even the floor of the canyon is not free from this condition. A badly broken zone lies beneath the east third of the canyon bottom, where the bedrock channel is deepest. At this level the east portion of the rock floor of the canyon appears to be less substantial than the west, whereas higher in the canyon sides, the west wall is more broken than the east.

Because of the existence of the same conditions beyond the site, together with the less favorable topography both up and downstream, it is not possible to find materially better conditions at any other location in the immediate vicinity of the forks.

The character of the rock in the west wall of the canyon, where the proposed dam would rest upon and against it, is displayed in the abutment excavation. It is here shown to be broken through by an intricate system of fault planes with dips ranging from essentially vertical through intermediate angles to flat-lying and with strikes to nearly all points of the compass. Some of the fault lines may be traced across the excavation in a north-south direction and they thus parallel the canyon, while others appear to be correspondingly extensive in transverse directions.

Fault Planes.—Intersection of the fault planes and joints with which the rock is traversed has separated or split

the mass of the abutment rock into blocks of all sizes. Evidence of movement between contiguous blocks is the presence of a film or band of clay gouge, which when wet is smooth and slippery clay, and when dry, crumbly and gritty. There is often also a variable thickness of fault-breccia or shattered rock.

The fault planes are lines or surfaces of relatively ready percolation of water, by which alteration and softening of the adjacent rock has resulted. The inner parts of the larger blocks are usually comparatively hard and fresh rock; those of the smaller ones crumbly or in varying state of disintegration.

In excavation, separation takes place most readily along the slip surfaces between blocks. Where these are steep and approach parallelism with the canyon side, conditions are favorable to slumping of masses, such as the body of broken rock included in the recent "side" at the northerly side of the west abutment excavation.

No Suitable Foundation Rock Found.—The test shafts, tunnels and borings so far made give little hope that the conditions described above will materially improve with continued excavation. These explorations indicate that no suitable foundation rock for a high masonry dam is available under portions of the west abutment to distances of at least 190 ft. horizontally and 150 ft. vertically beyond the present excavation lines.

At the present time the face of the east abutment excavation has the appearance of being less broken and more substantial than the west side. In excavating into this wall the rock has separated, leaving a face determined by a set of well-defined smoothed surfaces, nearly parallel to the natural slope at this side.

This coincidence of position of a plane of separation with the average slope of the canyon side is to an extent deceptive, for it gives less favorable opportunity to see the actual physical condition of the abutment rock than at the west side. In the top portions of the excavation, however, the same intricate combination of faulting and crushing appears as in the west side. There is reason, therefore, to anticipate that greater depth of excavation may show a similar degree of instability at other levels in this abutment.

While the present excavations and exploration tunnels in the east abutment give promise of more satisfactory foundations than are available in the west abutment, neither the tunnels nor the borings on this side extend far enough to settle this point definitely. Furthermore, even the best rears of rock in this abutment are sufficiently intersected by planes of weakness and joints, some of which contain soft material, to throw doubt on its suitability for a dam of the height proposed.

The bedrock in the floor of the canyon, as shown by the drill cores and by the shafts now being put down, is of the same types of rocks as the canyon walls. In portions of many of the drill holes only a small percentage of core, or even no core, was recovered on account of the poor condition of the rock and both fault breccia and clay gouge are found in some of the cores.

The inference to be drawn from all available data is that the foundation rock in the canyon bottom is broken and is traversed by fault lines to an extent comparable to what is seen in the canyon side walls and abutment excavations. There is good reason to believe that strongly developed lines of break run lengthwise as well as across the canyon floor. Weathering and oxidization are not so general at this lower level, although these effects in certain places reach as deep as explorations have gone.

The fundamental requirement for a high concrete gravity dam is that it be built on firm, sound rock, of uniform compressibility. This condition does not exist at the San Gabriel site.

The Unanimous Opinion of the Board.—It is the unanimous opinion of this board that the foundation conditions are such that the dam proposed in application No. D-175 cannot be constructed without creating a menace to life and property.

While the primary purpose of this report as covered in the preceding pages is to advise on the safety of San Gabriel Dam, as proposed in the plans submitted by the Los Angeles County Flood Control District, the board in its investigations has come to the conclusion that the foundations and other conditions are suitable for a properly built flexible-type dam of conservative proportions. Such a type would not only conform to foundation conditions, but would also provide a structure which can best withstand earthquake shock or earth movement.

Flexible Type Dam Could be Built.—The board is of the opinion that a combination earth and rock fill dam, placed by the hydraulic method with concrete core wall, can be constructed safely at the site under consideration. The location of the reservoir site above a thickly settled and highly improved valley necessitates unusual precautions in the design of the dam, such as limited height, adequate cutoff, large freeboard, flat slopes and an ample downstream toe blanket. It calls for a spillway of generous capacity, designed for maximum floor occurrence. Unless conditions as now disclosed are found to be materially different upon further exploration, the board believes a safe dam of this type can be constructed at this site. Such a dam should be of width up and downstream to provide a percolation distance (length of water travel) along the base of the dam, equal to at least eight times the maximum depth of water against the dam. In addition to these conservative proportions, the dam should be provided with a reinforced concrete core wall, extending a proper distance into the bedrock at all points, in order to increase percolation resistance. Sluiced mat should also extend to bedrock in an open cut on the two sides of the core wall, the mat immediately up-stream from the concrete wall constituting the impervious core, the mat immediately below the core wall to consist of sand only. Such construction would prevent the travel of water in dangerous amounts either around or under the dam, and would provide a safe structure even though the concrete core wall were breached. The surface of the abutments above the crest of the dam should be brought to slopes that will prevent slides. Materials excavated to date from the abutments can be utilized in the earth-and-rock-fill type of dam suggested above.

Inspection of Valves and Fire Hydrants

At the Third Annual Conference of the Maryland Water and Sewerage Association Carl A. Heckmer of the Washington Suburban Sanitary District, Hyattsville, Md., gave the following suggestions as to what constituted a proper inspection of valves and fire hydrants:

Valves.—Semi-annual inspection advisable through Fire Underwriters' requirement is yearly inspection.

Covered valve boxes should be brought to grade.

All boxes cleaned of debris.

Set valve key on nut—pour kerosene or diluted crank case drawings down valve key—oil will run down the valve stem, lubricate it and revive packing.

Operate valve up and down, thereby cleaning groove of sediment and rust which is pushed out sides of groove.

Count number of turns—same for same make and size. This will bring to light bent valve stems or debris under gate without actually closing down main.

Grease gears on large valves—clean teeth of gears with wire brush.

Fire Hydrants.—Physical examination of hydrant first, condition of operating nut, nozzle threads, general appearance.

Turn on water with all caps on—listen with aquaphone for leaks in drain valve or hydrant barrel—note if all nozzle caps are tight in hydrant—measure static pressure by placing one cap on hydrant with pressure gauge attached.

Turn off water—remove nozzle cap and note rate of drainage.

Flush out hydrant noting residual pressure on one nozzle and rate of flow with pitot tube gauge.

Production and Collection of Sewage Gas

Its Advantages in Eliminating Nuisance Around the Disposal Plant and Performing Useful Work, with an Account of the Installation at Springfield, Mo.

By GEORGE S. RUSSELL

Russell & Axon, Consulting Engineers, St. Louis and Springfield, Mo.

THE gases given off from the sludge digestion chamber of either an Imhoff tank or a separate system of sludge digestion are various. The principal constituent, however, is methane, or marsh gas, which can be burned, and as a heat producer has a value between that of the artificial and natural gases used for domestic cousumption. This gas in itself has very little odor, but the other gases with which it is combined, such as sulphurated hydrogen, give rise to most of the obnoxious odors found around a disposal plant.

It can readily be seen then, that if some method of collecting and burning this gas can be devised, we are performing two services. First, we are eliminating one of the worst nuisances around the disposal plant, and second, we may use this waste product to perform useful work.

Some of the large plants in Germany are now collecting the waste gases given off from Imhoff tanks and utilizing them in various ways, either at the plant itself or by piping it into the local gas mains.

The Antigo, Wis., Installation.—One plant in the United States which has made use of this idea, and has been of interest to engineers generally, is the plant at Antigo, Wis. In this plant, which is of the separate sludge digestion type, the gas from the digester is collected and burned in a hot water heater. The hot water from this heater is carried through coils in the digester and serves to increase the temperature of the sludge. On account of the severe winters at Antigo, bacterial reduction is practically nil throughout a large portion of the year and some method of heating the sludge is necessary for satisfactory sludge digestion. Due to the results obtained at Antigo, the writer decided that what was practically a necessity at Antigo might still be made an economy in Missouri.

The optimum temperature for bacterial action, especially as pertaining to sewage reduction, according to various investigators, lies somewhere between 70° and 80° F., while at 40° F. the bacteria are practically inert. As the temperature of ordinary sanitary sewage varies in this latitude from about 40° or 45° in the winter to about 65° or 70° in the summer it is readily seen that this bacterial action is never at maximum efficiency and during the winter months we are getting very little if any reduction. This requires additional capacity for storage of sludge during the time that the bacteria are dormant.

It can be readily seen, then, that less sludge capacity will be required where some provision is made for heating the digestion chamber than under ordinary conditions and if this saving in capacity and consequent saving in construction cost is sufficient to justify the installation and operation of heating equipment, then the latter type will be the more economical. The amount of saving will depend on the range of temperature in the locality where the plant is being installed.

The Plant at Springfield, Mo.—The new plant at Springfield, Mo., is one of the separate sludge digestion type and has a contributory population of about 45,000 people. The writer made alternate designs for the digestion tanks in this plant. The one allowing for no heating had a designed capacity of 2 cu. ft. per capita and required two 50-ft. tanks averaging 21 ft. deep. The alternate design was for a single tank, 65 ft. in diameter and averaging 20 ft. deep, equipped with gas domes and heating coils. This tank has a capacity of 1½ cu. ft. per capita.

The price bid for the latter alternate fully equipped with coils, heater, pressure regulator, etc., was almost exactly the same as for the larger capacity and this alternate was built.

Results at Springfield Plant.—The writer had hoped to have a full report of definite data on this plant to present at this meeting, but due to the breaking of one of the pipes in the heating system, our records are incomplete at this time. We trust that we may give you more exact information in this connection later. However, the writer has sufficient information to feel justified in stating that even for the period from May 1 until the present time the increased efficiency will more than justify the 25 per cent reduction in capacity.

The present sewage flow in this plant ranges from 2½ m.g.d. to about 5 m.g.d. and the gas production from 22,500 to 27,000 cu. ft. We estimate that it will take from 10,000 to 15,000 cu. ft. for the digester. The city is installing hot water radiators in the plant for winter heating purposes, which last year took about two tons of coal per week and we still feel that there will be an excess of gas.

The use of heat in the digester has kept the sludge in excellent condition. In spite of the fact that for nearly a month, a new creamery emptied sufficient milk wastes into the sewer to make the sedimentation tanks look like they were filled with milk, the hydrogen ion content of the sludge has never shown an acid condition, falling as low as 7.0 but averaging between 7.2 and 7.3.

It is therefore self-evident even at the present time that this heating of the sludge gives better digestion and eliminates many of the troubles usually experienced in the operation of this portion of a disposal plant.

Results That May Be Expected.—It seems that the collection of gas from a sewage disposal plant and the utilizing of this gas for heating purposes may well be expected to accomplish the following results:

(1) Eliminate odors incident to Imhoff tanks or separate sludge digestion by the burning of waste gases.
(2) Decrease operating troubles due to maintenance of optimum conditions for sludge digestion.
(3) Decrease first cost by reducing the amount of sludge capacity required more than enough to offset cost of heating system. (This depends on range of temperatures at point of installation.)
(4) Decrease operation cost, due either to utilizing the waste gas for heating of buildings at the disposal plant or the sale of this gas for heating purposes.

Acknowledgment.—The above is a paper presented at the 5th annual Missouri Water and Sewerage Conference.

North Carolina Section Elects Officers.—The North Carolina section of the American Water Works Association at its convention last month at High Point, N. C., elected the following officers:

C. W. Smedberg, Superintendent of the water department of Greensboro, was elected president to succeed McKean Maffitt. T. C. Patterson of Mount Holly, was named vice president to succeed P. T. Dishner of High Point. Both H. G. Baity of Chapel Hill, and E. G. McConnell, of Charlotte, were re-elected secretary-treasurer and editor, respectively. The 1930 convention will be held at Hendersonville, N. C.

Weather As Affected By Electron Migrations

Why It May Be Possible to Forecast Weather Changes with Considerable Accuracy Far in Advance

By HALBERT P. GILLETTE

AT least in temperate latitudes there is an almost continuous flow of electricity from the earth, into the air. The source of this current has puzzled scientists. Perhaps the most commonly accepted theory is that of Bauer, who believes that the electrons come from the sun, and that they enter the earth in the polar regions, flow to lower latitudes and escape thence into the air.

It seems to me unnecessary to assume a solar origin of these electrons. All that need be assumed is that electrons circulate between two great magnetic fields in the earth, a lower field and an upper field, the latter being the well known Heaviside layer of electrons, 75 miles or more above the earth's surface. Electrons moving in orbits constitute an electromagnet, and since electrons in the air as well as in the earth rotate a full circle every 24 hours, with the earth, they constitute electromagnets. But, being free to move, these rotating electrons are repelled or attracted by other magnetic fields, such as the fields of sunspots and the fields of other rotating bodies like the sun, planets, etc.

Most of the sunspots rotate in opposite directions in the sun's two hemispheres, and therefore have opposite magnetic polarity. Hence when sunspots of a given polarity (N or S) predominate, their magnetic fields must tend to repel, the earth's rotating electrons having similar polarity. Due to the inclination of the earth's axis there must be an alternation of repulsion and attraction every six months, according as the earth's north or south pole points most directly toward the sun. This alone would cause important migrations of electrons in the earth and its atmosphere. There is also to be considered the inclination of the sun's axis, for the sun itself is a huge magnet. Finally, every one of the seven visible planets, not to mention several others not yet visible, must be counted upon to produce periodic migrations of the electrons in the earth and its air, depending upon the position of the magnetic axis of each planet relative to the earth.

So we have abundant means for producing a never ceasing flow of the earth's electrons, at times slow and at other times rapid. In short, electron currents must always exist in the earth and its atmosphere; and we need not assume that a single electron travels from the sun to the earth.

When sunspots are most numerous, obviously the migrations of electrons between the upper and lower magnetic fields of the earth will be very pronounced. This explains the fact that aurora are very frequent at or about the time of sunspot maxima. There is a great sunspot cycle of 11.2 years, and a similar cycle of auroral frequency exists. I have seen no mention of an intermediate auroral "peak," but I find that there is frequently one that is very pronounced, about half way between the 11.2-year "peaks." I find that these intermediate auroral "peaks" occur when Jupiter's north magnetic pole points most directly earthward, and that at such times there is usually a rainfall "peak" also. Douglass had previously noticed this intermediate rainfall peak, but had offered no explanation of it.

In this connection it may be well to point out that although the 11.2-year sunspot cycle is very regular, the corresponding rainfall cycle is less regular; for the earth is revolving around the sun at a mean distance of about 93,000,000 miles, and Jupiter is revolving at a distance five times as great and with an orbital velocity less than half that of the earth. In consequence of the changes in relative position of these two planets, there is a seeming lack of periodicity in the rainfall due to Jupiter's magnetic effect on the earth's electrons; but it is easy to calculate just when Jupiter's magnetic axis points most directly earthward; and I find that in every such case there has been a marked increase in rainfall in northern latitudes, provided that it was during the rainy season. This proviso merely means that Jupiter's magnetic field must be assisted by the fields of the earth and sun if much rainfall is to result.

The earth's axis is most inclined relative to the sun about June 21 and Dec. 21; and the sun's axis is most inclined relative to the earth about Mar. 8 and Sept. 8. Hence between Sept. 8 and Dec. 21, there occurs the maximum migration of electrons toward the north pole, and the converse between Mar. 8 and June 21.

In addition to the migration of electrons, there are two other important factors that affect the number of electrons in any region, namely, temperature and pressure. A rise of temperature releases electrons from atoms, and so does a fall of pressure. Hence in the summer and early autumn, electrons increase in number, which accounts largely for the thunder storms at that time. At high altitudes the electrons are more numerous than at low altitudes, which assists in explaining the increase in preciptation at high altitudes; for wherever electrons are numerous electron-whirls are most powerful, other things being equal, and electron-whirls impart a spirally ascending motion to the air.

Electron-whirls are caused by the action of the earth's magnetic field. This explains why cyclonic storms rotate in opposite directions in the earth's two hemispheres. I have little doubt that practically all air currents of meteorological impotance are created by electron-whirls. If so, weather is primarily an electrical phenomenon; and since electrical changes in the earth and its air are mainly the results of astronomical factors (sun, planets, etc.), it will become possible to forecast weather changes with considerable accuracy, far in advance. Eventually such forecasts will state approximately the inches of rainfall in each district during each rainy season. Indeed I shall not be surprsied if it becomes feasible to estimate the rainfall by months, with no slight degree of accuracy.

Ohio Filter Men Meet

The 9th annual Ohio Conference on Water Purification, was held Oct. 24 and 25, at the Fort Hayes hotel in Columbus. Of special interest were papers presented on the taste and odor problem and the sanitation of swimming pools. Visits were made to the Marble Cliff Quarries and to the new water softening plant at Marysville.

Officers for the ensuing year were elected as follows: O. F. Schoepfle, Sandusky, chairman; F. E. Sheehan, Portsmouth, vice chairman; J. M. Montgomery, Piqua, secretary-treasurer; Geo. M. Lieber, Fremont, and J. Sheldon Scott, Steubenville, members executive committee.

Fremont and Dayton invited the conference to hold its 1930 conference in those cities. Action with regard to the location for the next year's conference will be decided by the Executive Committee, which will be influenced by the choice of meeting place for the fourth Annual Sewage Treatment Conference. Its meeting place also is to be decided by its executive committee.

Announcing Three New Editors

We take pleasure in announcing that three new associate editors, each an outstanding authority in his field, have been added to the staff of *Water Works and Sewerage*. Mr. John R. Baylis will have a section on Walter Filtration Plants; Mr. John R. Downes will have a section on Sewage Disposal Works and L. H. Enslow will write on Sanitation, particularly the application of chlorination in the water works and sewerage field.

Mr. Baylis is Physical Chemist, Division of Operation, Bureau of Engineering, Department of Public Works of Chicago. He is in charge of the experimental work on the filtration of the Lake Michigan water for Chicago, and in this capacity designed the Chicago Experimental Filtration Plant, which is the largest and most elaborate plant of its kind ever constructed. Previous to coming to Chicago in 1926 he was principal sanitary chemist, Montebello Filters, City Water Department, Baltimore, Md.

Mr. John R. Downes is Supervising Engineer of the Plainfield and Dunellen, N. J., Joint Sewerage Disposal Works. Mr. Downes has been active in the sewage disposal field for many years. He was in charge of the sewage disposal works of Plainfield, N. J., from 1913 to 1916, in the latter year becoming supervising engineer of the joint sewage disposal works. He was the first president of the New Jersey Sewage Works Association and he was largely responsible for the establishment of the New Jersey Experimental Station.

Mr. Linn H. Enslow is Research Engineer of The Chlorine Institute, Inc. Mr. Enslow in collaboration with Abel Wolman developed the excess chlorine or "residual chlorine" method of controlling chlorine dosage, which is now in universal use in the sanitary field. He formerly was superintendent of the filtration plant of Spartanburg, S. C., and later of the filtration plant at Gatun, Canal Zone. He has been research engineer of The Chlorine Institute since 1925.

These new editors were selected because of their particular fitness for the work they are to handle. Thus the readers of Water Works and Sewerage will be kept informed of the very latest developments and the best practice in the water purification, sewage disposal and chlorination fields.

Hoover's Great Construction Program for 1930

There has been a reduction in the construction of dwellings and industrial buildings (but not in public works) during the past six months. On the heels of this came the stock market slump. President Hoover and his great secretary of the treasury, Andrew Mellon, have announced that they do not regard the deflation of stock prices as an evidence of business weakness. On the contrary they attribute the decline in building to the high rates of interest brought about by abnormal stock market speculation and the flow of money into Wall Street.

Now that the stock speculation bubble has burst, Hoover has announced that he favors a great expansion of public works; and as the first great step in this program he proposes extensive river improvements and canalization that will ultimately result in reduced costs of transporting grain, coal, etc. He also favors enlarged programs of municipal, county and state construction of pavements, roads, water works, sewerage systems, etc. Without doubt the president's great prestige as an executive, engineer and political economist will cause his recommendation to be adopted. So there is assurance that 1930 will be the greatest year of public works construction in the history of America.

In addition to the impetus thus assured under the Hoover plan, it should be remembered that gasoline taxes are financing most of our road improvement programs. In California the monthly gasoline tax incomes are running 16 per cent ahead of those of a year ago. Most of the other states are also showing remarkable increases in gasoline sales, which means corresponding increases in funds available for road construction. Nor should the effect of increased production of automobiles and motor trucks be overlooked, not merely because of its effect on gasoline consumption but because of the increase in the number of voters who will insist upon having better pavements and wider and better roads. It is now certain that the total number of American motor cars and motor trucks produced in 1929 will be about 5,500,000. The old cars are not being scrapped at the rate that once was common, for cars are more durable and we are rapidly becoming a two-car-per-family nation.

As a result of President Hoover's business and economic conferences the greatest construction program in the history of the country has been developed for 1930. It is estimated that this will amount to over $10,000,000,000 and will include the following:

Roads and Streets	$2,200,000,000
Waterworks and Sewers	700,000,000
Steam Railway Construction	400,000,000
Federal Government Construction	750,000,000
Public Utilities	1,000,000,000
Building Construction	5,500,000,000
Total	$10,550,000,000

Nation's Purchasing Power Not Affected by Stock Deflation

In not a few recent articles it has been said that, aside from some reduction in the buying power of the "fleeced lambs," no industrial injury has occurred as a result of the drastic deflation of stock prices. A little thought shows that not even this reduction in buying can affect the total buying power of the nation.

To begin with the earnings of the stocks remain unaltered by their reduced market prices, and it is only their earnings that furnish buying power. The dividends may go to other owners, but this is merely a transfer of buying power. The annual surpluses remain with the companies, so the buying power that those surpluses represent does not change hands.

As to "paper profits" resulting from a rise in stock prices, they are not buying power until the stocks are sold and the profits are actually made available; but when that occurs, and money is transferred, by as much as the seller gains in cash with which to buy goods the seller loses in cash. So, in the final analysis, the total buying power of a nation is unaltered by any change in the prices of stocks, so long as no international trading is involved. International trading in stocks is trivial in comparison with national trading, so this factor need not be considered.

The well known and oft-repeated truth is that the vast majority of Wall St. transactions that involve stocks are gambling transactions. It is pure sophistry to argue that many of the stock buyers and sellers are investors, for active stocks are turned over so frequently that the nature of the transaction is clearly apparent. Most of us have a gambling instinct, so when public gambling on horse races and the like is barred by law, many of us turn to a sort of gambling that is not thus prohibited, and we call it speculating. We are far from implying that laws should be drawn to prohibit or even to curtail buying on margin. On the contrary, let freedom be unconfined, except, perhaps, that phase of it that enables pools to rig the market. Sooner or later men will learn that intrinsic values are not in the habit either of skyrocketing upward or of falling like the stick; and it is better that they learn to beware of such stock markets as we have witnessed in recent years than that they be forbidden to speculate.

In this connection it may be well to point out why many stocks had such a spectacular rise for several years following the close of the world war. Take, for example, public utility stocks. The editor, as a consulting engineer on public utility appraisals and rate cases, was employed by many public utility companies for several years following the war; and testified before commissions and courts as to the rise in wages, materials, taxes that made higher rates of charge necessary. Also it was shown that the values of utility plants had risen as a result of the rise in wages and in prices of machinery and materials; and fair percentages of profit on these higher values were likewise necessary under our constitution. As a result of such hearings, of which the ones in which the editor was engaged, were merely typical of hundreds, the rates of street car fares rose from 5 cents to an average of about 7 cents, and other similar, although usually smaller, increases were secured by utility companies in other fields. Prior to these increases in rates, utility common stocks had declined in price because of inadequate earnings. As increased rates went into effect, such stocks began to rise, and in many instances they increased several fold in price. Seeing such increases in stock values, accompanied by earnings that fully justified the increases, the public eventually came to think that there was no end to the gifts of the Santa Claus they called our American prosperity. So they began discounting anticipated increases in earnings of utilities and railways that were destined not to occur.

In the industrial field a general rise in earnings was also largely due to rise in prices of products, resulting from the inflation in currency that the war had caused. Here the effect was more spectacular than in the utility and railway fields, because it was more sudden. It was sudden because commissions and courts did not delay the rise in rates of charge. Competition usually could not check the rise, for a competitor had to buy lands and plant at prices that had advanced, and was thus forced to charge higher prices for his products, except in those rare instances where a complete offset to such increased costs could be secured through increased efficiency of machinery. Let the value of an industrial plant and lands double as a result of currency inflation, let that plant be mortgaged for half its original value, and let common stock at par equal the value of the other half. Then what happens is this: A plant capitalized at $1,000,000 (half bonds and half common stock) becomes worth $2,000,000, on which the bond holders have a lien of $500,000, leaving an equity of $1,500,000 that belongs to the holders of $500,000 par value of common stock, which now becomes worth $1,500,000, or triple par. As such a stock works up to such a triple value, speculators become inflamed by the sight of rising values. Many who buy secure enormous profits during the rise, and become imbued with the idea that they are Napoleons of finance. Not understanding the underlying cause of the rise, they attribute it entirely to American prosperity. They read that never before has our nation increased per capita productivity so rapidly (which is true, but not the cause of rising prices). They see no reason why this productivity should not continue to mount, so they infer that stock prices will continue to mount, and err because their premise is wrong. Increasing per capita productivity does not increase prices; it decreases them. The industrial companies who are able to show rising net earnings per dollar of invested capital are only those that excel the others in efficiency. These, however, are in the minority, but they are a spectacular minority; and the continued rise of the value of those stocks adds fuel to the speculative furnace—until, at last, the boiler explodes.

Almost any stock purchased seven or eight years ago, following the post-war panic, was a bargain. Such purchasers came to believe that they had shown wonderful business acumen, when, if the truth were known, very few of them had correctly analyzed the problem, if we may judge from the writings of financial advisers during the last eight years. Babson, just before the recent crash, issued a warning to sell, but it is apt to be forgotten that he issued a similar one in 1921 at the very time that he should have been advising the purchase of stocks. And up to the very moment of the recent debacle, the great majority of the professional prophets in the realm of speculation were as optimistic as such prophets usually are.

During the editor's investigation of public utility rates, he analyzed the rates of return on the market values of all classes of American securities for many years back. Some of the conclusions thus derived were published in "Engineering and Contracting" and "The Analyst." The relation between the risk factor and the earnings of bonds and stocks was deduced; and the average "market price of money" was derived. Just before the recent bursting of the stock bubble of 1929, many stocks were selling at more than double the price warranted by the risk factor and the earnings. It was evident from such facts that "frenzied finance" was due for a fall. Many a banker had come to that conclusion. Our Federal Reserve System had issued repeated warnings. But it is the characteristic of nearly every one of us to be oblivious to such warnings, especially when we have ignored them and profited by ignoring them for a year or more. More than two years ago the warnings began to come from conservative bankers, but investors listened to market tipsters instead, and the headache of the day after is now theirs. We are deeply sorry for them. We have ourselves experienced, many years ago, their every feeling. Out of that bitter experience came the resolution never to buy stocks on tips, but to study methods of correctly appraising the intrinsic values of securities. You will be told that no values are intrinsic. This is quibbling over a definition. Certainly there are stock prices that exceed the present worth of prospective earnings, just as there are others that are below that worth. The successful investor, as distinguished from the speculator, first learns to appraise intrinsic values, and then backs his own judgment and not that of some tipster who sells or gives him advice but risks no money of his own.

Why Rock-Fill Dams Are Best Over "Dead Faults"

In several recent reports on dam sites in California, geologists and engineers have used the expression "dead faults," and "crustal stresses long ago adjusted." It is our opinion that there is no such thing as a "dead fault," if by that is meant a crustal crack along which no further movement will ever occur. To begin with it is little more than a guess to say that no recent movement along a fault has occurred, if by recent is meant within a century. And as for saying that no future movement will occur, obviously that is the wildest of conjectures. There are many instances of volcanoes that had been "dead" for generations, yet suddenly became alive. What, then, is the criterion of "death"? Only long inactivity, but "long" is an indefinite and purely relative term. At best the only sound inference that can be drawn from long inactivity is that the volcano is dormant. When it will awake, no one knows, but that it will awake some time is probable. The same is true of crustal movements along faults.

The editor has published evidence that indicates clearly the cyclic nature of volcanic and earthquake phenomena, as well as those great crustal movements that have elevated or depressed large continental areas. More evidence of the same sort will soon be published. Since application of the mathematical rules of probabilities to these data very strongly support the cyclic theory of crustal movements, both great and small, it is no longer logical to speak of any fault as being dead.

This being granted, it follows that no rigid dam should be built over a fault in any region where crustal movements are prevalent. The St. Francis dam is a case in point. It straddled a "dead fault" that suddenly came to life. See "Engineering and Contracting" (April, 1928) for the measurements that showed that a crustal movement took place after the dam was finished, and probably compassed its destruction.

The San Gabriel (Calif.) dam site is under investigation by several geologists and engineers. Already there is disagreement among the doctors, some alleging that the fault at that place is "dead," others, that it shows signs of recent slippage. It is not very material whether recent slippage has occurred or not. That slippage will occur some day is probable, for the region is one of repeated, although slight, crustal movements; none of which would injure ordinary structures, but any of which might destroy a rigid dam.

In a previous editorial article we advocated the use of a "rock-filled dam" for this site. After the writing of that article, but before its publication, E. C. Eaton, Los Angeles County flood control engineer, reported to the Board of Supervisors that it might be wise to substitute a rock-fill design for the concrete, at least on the west abutment. He recommended a careful study of the 250-ft. rock-fill dam at Bowman, near Fresno, Calif. He suggested that the eastern part of the dam be made of concrete as originally designed. It is our opinion that it would be wiser, and probably cheaper, to make the entire dam a rock-fill structure about 250 ft. high. It would then be flexible throughout, and unquestionably safe.

No rock fault should be regarded as being unquestionably dead. Hence dams over faults should be either earth or rock-fill or a combination of both, well sheeted on the upstream face.

Since the foregoing was written, New England has experienced the most severe earthquake shock in 174 years. Incidentally, crustal movement along the Dundian fault, near the Bay of Funday, is believed to have severed nearly half of the score of cables that cross the Atlantic Ocean from that region. The first Atlantic cable was laid in 1858, more than 70 years ago, and this is, we believe, the first instance of cable breakage due to a crustal movement. Had geologists been previously consulted as to the risk of such an accident near the Dundian fault, it is likely that there would have been a difference of opinion, with the majority inclined to call it a "dead fault." In some respects geology is almost an exact science. In most respects it is still embryonic and very inexact. Of this the editor is convinced both by his college training, as a mining engineer and by his recent studies of crustal movements and the geological literature on the subject.

Badger Meter Mfg. Co. Has Biggest Year—Holds Its Annual Sales Meeting

THE accomplishments of the company during 1928 were the key notes of the annual sales meeting of the Badger Meter Mfg. Company, which was recently held in its home office at Milwaukee, Wis. The officials of the company pointed out the strides made during the past year, and also stated that 1928 was the biggest year in the history of the company, which is now in its 26th year. This was duly credited to increased manufacturing space and facilities, additional sales representatives, and a more complete line of water meters.

During the year 1928, the company made an addition to the plant which covered a half block square, giving it an increased floor space of 45,000 sq. ft. in the manufacturing and assembling buildings. Besides this addition a new brass foundry was constructed, having 15,000 sq. ft. of floor space and equipped in the newest and latest type of machines, which makes this foundry one of the most outstanding of its kind in the field.

What News

Coming first by runner, and horse and rider, then stage-coach, steam-car, telegram, cable, down to the days of wireless and airplane, from North—East—West—South, NEWS has been eagerly watched for by a waiting world. The little world watching for the NEWS we have to give is just as eager to know of the happenings in the engineering field—how the output of the manufacturer is increasing and how the distributor is handling it. And, to be a worthy distributor of this information it must come to us from all four quarters — North — East — West — South,—how else could it be NEWS.

Wherever you are, let us tell your news to our engineering world. Anything that is of interest to the growth and welfare of your business, is of interest to us. Send your stories and pictures to The Editor, Distributor News, Gillette Publishing Co., 221 East 20th Street, Chicago.

During the past year some new models were added in order to give Badger Meter a complete line, which new line includes a size and type for all service, from the little ⅝ in. disc meter to the large 12-in. turbine. In accomplishing this the company redesigned its line of compound meters, which now range in sizes from 2 in. to 8 in., complying fully in detail with the American Water Works Association and the New England Water Works Association's standards with reference to laying lengths, likewise establishing capacities averaging 25 per cent greater than standard specifications demand. In addition to this, it reduces the net weight of all sizes of this type of meter on an average of 50 per cent through special cast-iron processes developed, this because of greater tensile strength. Naturally, it makes for increased ease of handling on installations and maintenance. Many developments of a material nature were reported in the Badger turbine meters, which range in sizes from 2 in. to 12 in. All changes were made to increase efficiency and serviceability.

Further refinements were included in the disc meters, which range in sizes from ⅝ in. to 6 in., also in the split case type. This centers itself around the standard oil-enclosed gear trains.

The officers of the company reported that the company's engineering staff and research laboratory staff have been added to considerably and have mapped out a definite program of activities which will keep Badger meters abreast of the demands of the field and will introduce such new meters as are necessary from time to time to increase

meter efficiency. During the past year the company has successfully developed an automatic batch water meter for accurately measuring water on central concrete mixing plants, also a companion concrete batch mix meter for installation on portable concrete mixers.

During the past year the company's industrial meter division has been expanded and now represents a much greater variety in fluid measuring developments, covering hot water, oil, grease, gasoline, brine and acid meters. An electric alarm register set-up for practical application for measuring equipment as applied to water softeners was also developed.

The company's sales conference was concluded with a banquet at the Milwaukee Athletic Club on the last evening of the meeting. Twenty-five of the company's sales representatives, in addition to district managers and other members of the personnel, attended the meeting. The sales representatives came from all parts of the country, but the attendance was much affected by the influenza epidemic which swept the country at the time this meeting was held.

Modern Plumbing in Land of King Zog

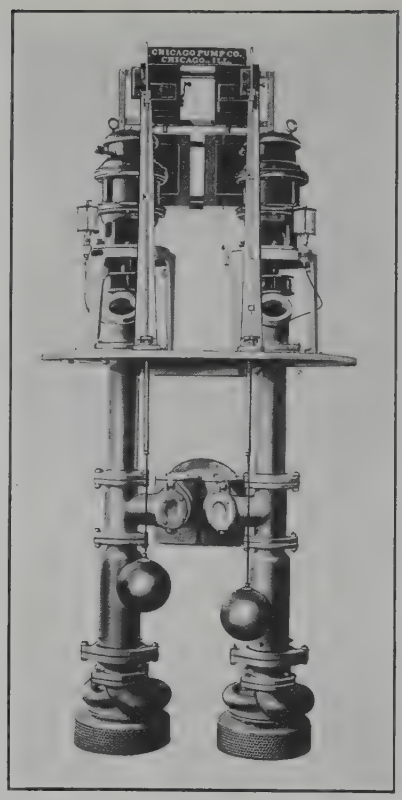
This is a story of Tirana, the home of King Zog of Albania, and it seems as if it ought to begin "Once upon a time," but if it did it would be a fairy story, and this is a true story and the time is NOW 1929.

Tirana is located just northwest of Greece, and King Zog is the newest ruler in Europe, and being a modern king, he wanted some modern improvements, so last month Tirana was supplied with electric lights for the first time in its history.

In spite of the new and modern king and the new and modern electric lights, Tirana is still something of a fairy story appearing town, for the streets are unpaved and there are no sidewalks. On both sides of the narrow main thoroughfare oriental bazaars display their wares—merchandise of all kinds.

There are no "Stop and Go" signals in this town and donkeys laden with wares and women carrying bottles of water on their heads jostle one another in the streets, and to the stronger belongs the right-of-way.

Here then in this town with the fairy-story sounding name and its medieval setting has appeared one of the very latest types of sewage ejectors known to civilization. As soon as the power necessary for operation was available this modern plumbing installation was selected by the American Legation at Tirana.



"Flush-Kleen" product of Chicago Pump Company, chosen by American Legation for installation at Tirana, Albania

Because of the scarcity of mechanics who are familiar with this type of equipment and because repair parts, if needed, would be hard to get, the engineers working for the American Legation gave heed to these matters, and for this reason the manufacturers of the "Flush-Kleen" Sewage Ejectors are pleased that this type of equipment was chosen for the work.

So the "Flush-Kleen" Ejectors have gone to work in the land of King Zog, and it probably won't be long now before the natives and the modern king take up the cry of "Bigger and Better Tirana", and Tirana storekeepers will have to move to other quarters to make way for the steam roller.

Promotions

The Lincoln Electric Company, Cleveland, Ohio, announces that Mr. J. E. Durstine has been advanced to district sales representative for the Southeast, with headquarters at Birmingham, Alabama. Mr. H. P. Egan has been made district sales representative for central Ohio. He will be located at Columbus.

The Lincoln Electric Company are manufacturers of Stable-Arc Welders and Linc-Weld Motors.

To Develop Water Systems on Guaranteed Basis

The Fairbanks-Morse Water Supply Co., Chicago, Ill., has been organized recently to handle the complete development of water supplies on a basis of guaranteed quality, quantity and cost. The parent organization, Fairbanks, Morse & Co., has, of course, been a builder of pumps for many years and has during that time supplied pumps for many of the large municipal and industrial plants of the country. The new subsidiary organization, however, approaches the water supply from an entirely different angle.

After a thorough geological survey and hydraulic investigation of a plant's water supply has shown favorable possibilities, the Fairbanks-Morse Water Supply Co. agrees to deliver a definite quantity and quality of water at a definite price per 1,000 gal. The plan is worked out so that the municipality is not required to invest any money in the pumping plant. Water may be purchased at a fixed price for a period of years, at the end of which time complete title to the plant passes to the city. At any time during the period the municipality has the option of taking over the plant.

Several installations of this character are now being developed. One of these is that of the City of Havre, Mont., where a supply of 3,000,000 gal. a day was guaranteed at an investment cost of $72,000. Three plants are being developed for the city of Brooklyn, N. Y., which will be used for furnishing water for sluicing ashes at incinerator plants. At Muskegon Heights, Mich., another guaranteed supply is being developed.

The Fairbanks-Morse Water Supply Co. is headed by P. D. Bowler as vice-president and general manager. Mr. Bowler was one of the founders of Layne & Bowler Corp. and was president and general manager of that organization for many years.

P. D. Bowler

The Hooker Chemical Plant at Tacoma Begins Operations

THE Hooker Electrochemical Co. of Tacoma, Wash., and Niagara Falls, N. Y., has just completed and put into operation its plant at Tacoma Tide Flats, construction of which was started last August. This is a record in construction of this type. The cut taken from a drawing of McKim, Mead and White, architects, shows the building to be of a permanent character and pleasing in appearance. The site comprises about twenty acres, located on Alexander Avenue near Hylebos Waterway. In choosing this site the officers of the company secured convenient shipping facilities, satisfactory power supply and rates, without excessive land values. These features allow a central distributing point for liquid chlorine and a convenient foreign outlet for caustic soda.

Tacoma Plant of Hooker Electrochemical Company from drawing by McKim, Mead & White, Architects

The twenty-five years of experience gained by the Hooker Company in their Niagara Falls plant, which was started on a small scale and is now one of the largest chlorine producers in the country, has enabled them to open the Tacoma plant on a large scale. With the exception of a few skilled executives transferred from the eastern plant, the personnel of the western organization is made up of western men.

The patents covering the Townsend Cell (the process of manufacture whereby electric current is passed through a brine solution made from common salt, thus securing the elements sodium and chlorine), are owned by the company. This process is economical in power consumption and requires a minimum floor space per ton of output, in that Townsend Cells can be efficiently run at over 5,000 amperes. About twenty different chlorine products are now being manufactured at the Niagara Falls Plant, and these products will be duplicated in the west as the demand arises.

Elon H. Hooker, President of Hooker Electrochemical Company

The two main raw materials for this plant are power and salt. The power is supplied under a contract with the Department of Public Utilities of the City of Tacoma, and the salt is secured in New York, Louisiana, California and from Spain, Italy and China. Handling facilities permit of it being unloaded at a rate of 1,000 tons a day, and it is stored in steel tanks to provide for full capacity operation for many months.

The general supervision of the sales work of the company is in the hands of Mr. M. H. Hooker, one of the three vice-presidents, while Mr. A. H. Hooker, Jr., is sales manager for the Tacoma plant. Mr. Hooker, Jr., has his headquarters in Tacoma and is available at all times for consultation on sales service problems.

The general administrative offices of the company are located at 25 Pine Street, New York City, in a building owned by the company, and in this building Mr. Elon H. Hooker, president of the company, has his offices. Mr. Willard Hooker and Mr. E. R. Bartlett serve the company as vice-presidents, and Mr. Bartlett also occupies the position of works manager for the plants at Tacoma and Niagara Falls. Mr. R. L. Murray is superintendent of the plant at Niagara Falls, and Mr. J. A. Flynn fills this office for the Tacoma organization. The other officers are Mr. J. M. Rowland, chief engineer; Mr. A. M. Hooker, technical director, and Mr. L. A. Ward, secretary.

The present capitalization of the company is $2,700,000 6 per cent cumulative preferred stock, par value $100.00, and $2,500,000 common stock, $100.00 par value, paying 6 per cent annual dividends. The bonded indebtedness is approximately $3,500,000, of which $1,500,000 6 per cent service B bonds were recently sold. It is believed that the investment in the Tacoma plant is something in excess of $1,500,000.

Follow Through

The Insley Manufacturing Company, engineers and manufacturers of Indianapolis, Indiana, and a division of the National Equipment Corporation, has issued in booklet form, for the use of their salesmen, all trade paper advertising to be used by them during the first six months of the year. Because it seems such a practical thing to do, we quote the statement which appears on the cover:

"Good advertising is nothing more or less than the assembly in printed form of the sales experience of an organization and the selling points proven to be most effective, to the end that the work of the salesmen in selling the customer is made easier, and the efficiency of the salesman is therefore increased.

"We want our salesmen to know our advertising, and to use it effectively. Each Insley advertisement has, or should have, a separate basic idea or sales appeal, which either advances our products in the esteem of the prospect or meets resistance that may be in his mind. The salesman should know these points, watch for new ones and incorporate them in his sales presentation.

"With this idea in mind we have had proofs of our Trade Paper Advertising for the first six months of 1929 made in booklet form, and request that you put it in your Insley Sales Manual, and refer to it occasionally. We hope it will help you yourself develop new ideas, and that it will help you put these ideas across with your customers. If it does this, it is good advertising."

All distributors will see the logic and good sense in the Insley Manufacturing Company, asking their salesmen to study their national advertising, and the same reasons which make it advantageous to these salesmen, will make it equally valuable for distributors to study the advertising of all the lines which they represent. Insley has presented this method to their men in a very compact and convenient form, but distributors could make their own booklets, containing, just as the one described, all advertising presenting their lines for from three to six months, as the advertisements appear, and study them. Take advantage of the national advertising which the manufacturers give you, and follow through.

Uniform Name Adopted for International Cement Companies

According to a statement issued by Mr. H. Struckmann, president of the International Cement Corporation, all subsidiaries of this corporation in the United States, as well as the Cuban Portland Cement Corporation, Argentine Portland Cement Company and the Uruguay Portland Cement Company, will be known as the Lone Star Cement Company. This change in no way affects the management, policies or products, but is one in name only.

The name, now universally adopted, had its origin about 30 years ago in the "Lone Star State," when a small mill in Texas began to produce Lone Star Cement, and which was to grow into a chain of 13 mills with an annual capacity of 20,000,000 barrels, under the direction of the International Cement Corporation, formed in 1919, when the annual capacity was 2,900,000 barrels.

While each Lone Star Cement Company is an independent organization, the resources of the International Corporation are available for scientific research and support in all modern practices. "Incor," a perfected high-early-strength Portland Cement is one of the achievements of the International System. This product was used in the construction of the Moffat Tunnel, and also in the Arlington Memorial Bridge, over the Potomac River from Washington, D. C., to Virginia, now under construction.

The mills of the Lone Star Companies are located in Alabama, Indiana, Kansas, Missouri, Louisiana, Pennsylvania, Texas, New York and Virginia, as well as the foreign countries previously mentioned. Cooperation between these companies enables them to render rapid, dependable service.

Road Show Queen Rides a Caterpillar

Miss Lily Damita, starring with Ronald Colman in The Rescue and The Bridge at San Luis Rey, who was acclaimed Queen of the Road Show at Cleveland, during her personal appearance in that city. "Good Roads lead to Good Movies," said Miss Damita, "and both are great educators and instruments of peace and understanding." This is the first "Caterpillar" Ten of the line and already famous as the most traveled and viewed tractor in the world. It has traveled over 10,000 miles and has been seen by over 1,000,000 people. Gov. C. C. Young's daughter unveiled it at California State Fair. "Jimmy" Walker unveiled it at Eastern States Exposition.

Gorman Joins Wallace & Tiernan

Arthur E. Gorman, well known sanitary engineer, has joined the staff of Wallace & Tiernan, and will be located at the headquarters of this company in Newark, N. J., on sales promotion work. Mr. Gorman has served the Department of Public Works of the city of Chicago as chief sanitary engineer, and more recently as public health engineer for the Sanitary District of Chicago.

He entered the service of the city of Chicago in January, 1924, following the water-borne typhoid fever outbreak on the South Side in the fall of 1923, prior to which time he served for six and a half years with the United States Public Health Service as an assistant and associate sanitary engineer. A very effective system for supervision and control over the chlorination of Chicago's water supply was installed under his direction.

The American Water Works Association, in June, 1927, awarded to him the John M. Diven Memorial Medal, as the member "who has best served the Association during the year." For two and a half years he served the American Public Health Association as secretary, and last year was made chairman of the Public Health Engineering Section of this association. When the American Water Works Association met in Chicago in 1927 he was secretary of the Chicago Local Committee, and last fall at the Fifty-seventh Annual Meeting of the American Public Health Association in Chicago, he served as Convention Manager.

Mr. Gorman has a wide acquaintance in the waterworks and public health profession and has the best wishes of his friends in his new undertaking.

Cutler-Hammer, Inc.

According to a recent announcement the Cutler-Hammer Manufacturing Company of Milwaukee, Wisconsin, has become Cutler-Hammer, Inc. The new company is organized as a Delaware corporation with the following officers: Chairman of the Board, R. F. Bacon; President, B. L. Worder; Vice-president, F. L. Pierce; Vice-president, J. C. Wilson; Treasurer, H. F. Vogt; Secretary, W. C. Stevens.

The Board of Directors announced are: F. R. Bacon, Milwaukee, Wis.; F. L. Pierce, Milwaukee, Wis.; B. L. Worden, West Orange, N. J.; Carl A. Johnson, Madison, Wis.; T. Johnson Ward, New York, and L. A. Lecher, Milwaukee.

In the change from a Wisconsin to a Delaware corporation the Cutler-Hammer Mfg. Co., of Milwaukee, the Cream City Foundry Co., of Milwaukee and Cutler-Hammer Manufacturing Co., of New York, are united under one name. They are identified with the manufacture of electric motor control, wiring devices and allied lines.

Timken Steel & Tube Co. Plans $1,000,000 Expenditure

A 200-acre tract of land, extending 2 miles west of this company's present holdings, has been purchased to put into effect during the coming year an expansion program which will amount to about $1,000,000. Room will be provided for future expansion, according to information received from the Timken Roller Bearing Company, of Canton, Ohio.

A tube mill, the first unit of this work, is now under way. This calls for a building 320 feet wide by 420 feet long, which will represent for building and equipment a cost of about half a million dollars. It is expected that this mill will be ready for operation by April 1st.

Palouse Tractor and Equipment Co. Takes Western Territory

According to newspaper story, the subdivision of the territory formerly served by the Hofius-Ferris Company in the far west, a new company has been organized to take over Whitman County, Washington, and Clearwater and Latah counties in Idaho, as tractor and equipment distributing headquarters. The new company will incorporate for $50,000 and operate under the name of The Palouse Tractor and Equipment Company.

H. W. Fairweather and L. J. Acuff, former residents of Spokane, become managers of the new company and will reside in Pullman, Washington. They were formerly interested in the Hofius-Ferris Company. Mr. L. C. Thomas, who had been serving as manager of the Pullman branch of Hofius-Ferris, will also be connected with the new organization.

Hercules Motors Declares Dividend

The year 1928 paid a total dividend of $5.00 to the stockholders of the Hercules Motors Corporation of Canton, Ohio, according to a report of a meeting of the directors held the last of December. A $2.50 dividend was declared July 1st, and the same amount January 2, 1929.

Business for the past year was reported as slightly in excess of 50 per cent over the previous year, and profits increased accordingly. Orders on the company's books for delivery during 1929 are already in excess of the total number of units shipped during 1928, and the increase of 1929 over the business of 1928 promises to be a large one, judging from present reports.

The following directors and officers were elected: H. H. Timken, Chairman of the Board; E. A. Langenbach, president; Chas. Balough, vice-president and general manager and H. P. Blake, Secretary. H. H. Timken, E. A. Langenbach, R. W. Gallagher, Gordon Mather and Chas. Balough will succeed themselves as directors.

H. Burdett Cleveland Announces New Member of Staff

Mr. Arthur L. Reeder, a member of the Society of Civil Engineers, and of the American Water Works Association has recently joined the staff of H. Burdett Cleveland, Consulting Sanitary Engineer, as Principal Assistant Engineer.

Mr. Reeder's experience in water purification and sewage disposal and construction, has been extensive. Over a long period of time he was connected with the Philadelphia Filtration Bureau, the Baltimore City Water Department and with the Pennsylvania State Department of Health. His most recent work has been in connection with installations at Reading, Pa., and Youngstown and Niles, Ohio.

The offices of these consultants are located at 225 Broadway, New York City.

Prest-O-Lite Establishes New Plant at Memphis

A new Prest-O-Lite Acetylene Plant, at 1241 North McLean Boulevard, Memphis, Tenn., commenced operations December 19, 1928. This plant, which is the thirty-sixth of the Prest-O-Lite chain, will supply nearby industries with dissolved acetylene for oxy-acetylene welding and cutting.

J. Brown is superintendent of the Memphis plant and C. A. Anderson, whose headquarters are at Birmingham, is district superintendent.

A. J. Sweet Joins Westinghouse

Mr. Arthur J. Sweet, formerly in consulting practice in Milwaukee, has joined the Commercial Engineering Department of the Westinghouse Lamp Company. Since 1910, when associated with the Holophane Company, Mr. Sweet has made extensive studies of street lighting problems.

In 1913 Mr. Sweet went to Milwaukee to become a member of the firm of Vaughn, Meyer & Sweet, and while serving in this capacity the City of Milwaukee adopted the recommendations of his firm for a complete new street lighting system. After severing his connection with this firm he entered into independent practice, which he continued until joining the Westinghouse organization.

Monarch Tractors Corporation Becomes Division of Allis-Chalmers Mfg. Co.

An announcement from the Allis-Chalmers Manufacturing Company, Milwaukee, states that the Monarch Tractors Corporation is to be taken over and operated as the Monarch Tractors Division, Springfield Works of Allis-Chalmers Manufacturing Company, effective January 1st, 1929.

The Springfield, Illinois, works will continue the manufacture and distribution of the Monarch Tractors, but will have the advantage of the larger organization and increased facilities gained through the new arrangement.

Change of Address

Announcement is made of the removal of the California Filter Company to their new headquarters, 981 Folsom Street, San Francisco, Calif.

Representatives or New Lines Wanted

Editor's Note.—From time to time we receive letters from distributors wishing to be put in touch with manufacturers of certain lines of equipment, or from manufacturers seeking representatives for their products. Items of this kind will be published and names and addresses furnished interested persons upon request.

New York corporation wishes to establish agencies throughout the country, prefer men specializing in heating and ventilating equipment.

A manufacturer of paving expansion joints is looking for distributors for northern California territory.

New York corporation, producing complete line of coal-tar products, wishes to make dealer connections throughout the country.

A contractor's superintendent, located in Florida, would like to represent some road equipment manufacturers in his territory.

A Michigan distributor, with many years' experience, representing at this time prominent manufacturers of pumping machinery, offers the services of an established representative to manufacturers needing increased facilities in this region.

Manufacturers' representatives located in New York would like to add line of heavy contractors' equipment of established reputation, other than the lines now handled by them. They would like exclusive sales rights for such equipment.

New York company would like to represent manufacturers not already established in eastern market, or who would like to make a change in their sales arrangements.

Machinery company in the east is interested in representing established lines of road machinery, with the exception of graders.

A man of many years' experience in the machinery business in the south would like to make a business connection for the sale of road machinery equipment.

Eastern Distributor handling Brick and Clay Products, and similar commodities, would be pleased to get in touch with manufacturers desiring eastern representation.

The Third Conference of the Machinery and Equipment Association is scheduled to be held at the United States Chamber of Commerce Building, February 14th.

Link-Belt Announces Three More West Coast Appointments

LAST August the Pacific Coast Division of the Link-Belt Crane and Shovel Department was opened in San Francisco by the Link-Belt Company, whose executive offices are located in Chicago. R. B. ("Buckets") Randall was made manager of this division, and Garfield & Company became agents for northern California and Nevada. At that time it was announced that several other appointments in the western terriory would follow.

In September A. H. Cox & Co., Seattle, was appointed as agent for Washington, and the National Machinery Co., Vancouver, for British Columbia. Now the announcement is made that J. L. Latture Equipment Company, Portland, has become Link-Belt crane and shovel agent for the state of Oregon and eastern Washington.

The National Machinery Company is

A. H. Cox, President

eminently fitted for handling British Columbia territory, and is ably headed by Mr. Newson as manager. All of the organizations named are well known throughout the northwest, and in addition to the Link-Belt account, they are representatives for several other leading manufacturers.

A. H. Cox & Company organized in 1910 to do a general machinery business, and in 1919 expanded and entered the construction equipment field. A. H. Cox, president, G. H. Jamison, manager of the construction equipment department, and W. F. ("Duggan") Lewis, formerly with Link-Belt Meese & Gottfried Company, are widely known in the crane and shovel industry.

The J. L. Latture Equipment Company was established in 1919. It now occupies a four-story concrete building which houses offices, display sales rooms

J. L. Latture, President

and warehouses. The president of this organization, J. L. Latture, enjoys a wide acquaintance among members of the contracting and logging industries of the northwest. The views we present with this story give a very good idea of the type of men and plants caring for the equipment machinery distribution in the far west.

The Link-Belt line of cranes and shovels, which has been supplemented by two new models within the past year, covers a range of sizes from ¾-yd. to 2 yd., each equipped and easily convertible as shovel, crane, dragline, trench shovel and skimmer excavator.

A. H. Cox & Co., Seattle

J. L. Latture Equipment Co., Portland, Ore.

Day & Maddock to Represent Erie Machine Shops

Announcement has been made of the appointment of Day & Maddock as distributors for the eastern Ohio territory for the Erie Machine Shops of Erie, Pa., manufacturers of Erie Steam and Gasoline Rollers. They will be located at West 82nd Street, south of Dennison, Cleveland, Ohio.

Linde Air Products Opens New Memphis Plant

A new oxygen producing plant was put into operation by The Linde Air Products Co., of New York, at Memphis, Tennessee, late in December. The new plant is located at 1241 North McLean Boulevard, with Mr. E. C. Heyman, superintendent of the old plant, in charge. The old plant, at 48 West McLemore Avenue, has been discontinued.

New Appointments

The Chicago Pump Company announces that the following representatives will handle their products during the coming year:

Ace Combustion & Engr. Co., 222 Milan St., Shreveport, La.; Harry Cooper Supply Co., 1224 Chemical Building, St. Louis, Mo.; F. L. Bunker, P. O. Box 1223, Greenboro, N. C.; L. Brandenberger, 149 W. 2nd St., So., Salt Lake City, Utah; Alfred P. Brown, Dexter Horton Bldg., Seattle, Wash.; John A. Butler, 18 Catherine St., Lynbrook, L. I.; Robert B. Brown, Newark, N. J.; J. J. Smith, 3620 Ednor Road, Baltimore, Md.

A Change of Address

The Southern Iron & Equipment Co., rebuilders of locomotives, cars, shovels, etc., who for the past twenty years have had their offices in the Grant Bldg. at Atlanta, Ga., have moved their general offices from the Grant Bldg. to their works at Hemphill Ave. and Southern Railway, Atlanta.

(Continued on page 40)

There is no standing still . . .

An Advertisement of the
American Telephone and Telegraph Company

During the past two years 6000 switchboards have been reconstructed in the larger cities served by the Bell System to enable the operators to give a more direct and faster service.

Previously in towns where there were more than one central office, your operator would hold you on the line while she got the operator at the other central office on an auxiliary pair of wires. Now she connects directly with the other central office and repeats the number you want to the other operator. You hear her do this so that you can correct her if there is any mistake.

This little change cost millions of dollars. Likewise, it saves millions of minutes a day for the public and it has cut down the number of errors by a third.

It is one of the many improvements in methods and appliances which are constantly being introduced to give direct, high-speed telephone service.

There is no standing still in the Bell System. Better and better telephone service at the lowest cost is the goal. Present improvements constantly going into effect are but the foundation for the greater service of the future.

Pavement Breakers, Drills, Compressors.—Several new pieces of literature have just been issued by the Sullivan Machinery Co., 122 South Michigan Ave., Chicago, copies of which will be sent upon request. Bulletin No. 81-V describes and illustrates the new K-2 Buster, for breaking concrete. This tool provides a wide degree of utility with economy in operation. Bulletin No. 81-S contains 32 pages and is devoted to rock drills. Full description and illustrations are given of model L-7 Rotator Rock Drill, steam rotator, DP-331 and light rotator, DP-321. Both of these bulletins are on heavy enamel paper in the loose leaf style, suitable for filing with other literature. Booklet No. 2007 is an attractive broadside illustrating portable compressors (which are given more in detail in Catalog 83-F), Drills, Spaders (Catalog 81-N), Portable Hoists, and Drill Sharpeners (new Catalog 72-I). If asking for any of this literature, we would appreciate it if you would give the name of our publication.

Hydrants, Valves, Etc.—Write to the Columbian Iron Works, Chattanooga, Tenn., for descriptive literature of the Columbian Fire hydrants, Gate valves, Valve boxes, Hydrant extension sections, or other water works equipment. We would appreciate it if you would mention our publication if asking for information.

Cast Iron Pipe.—United States Cast Iron Pipe & Foundry Co., Burlington, N. J., will be pleased to send you literature explaining the differences between the deLavaud Cast Iron Pipe and other types of pipe. This is a centrifugally cast pipe in which the graphite particles are finely divided and evenly spread.

Traffic Treads.—Alan Wood Iron & Steel Company, Widener Building, Philadelphia, Pa., have issued a new catalog illustrating and describing their "AW" Diamond Pattern Rolled Steel Traffic Treads and will be pleased to send copy upon request. These treads will be found of interest to highway officials and engineers who are put to it to prolong the life of wooden floor bridges and enable them to stand the wear and tear of modern traffic. On new bridges a traffic lane is determined upon and the treads laid accordingly, or are laid over the lines of traffic wear on old and worn floors. This company has branch offices in Boston and New York in the east, Dallas in the southwest and Seattle, San Francisco and Los Angeles in the west. Write to any of their headquarters for full particulars concerning this product. Kindly mention our magazine if writing for a catalog.

Tractors.—Caterpillar Tractor Company of San Leandro, Calif., and Peoria, Ill., has just issued a new 32-page booklet giving specifications and construction details of the new "Caterpillar" Ten. The track assembly with all its parts, the transmission, steering clutches, brakes, drive, and engine construction are thoroughly discussed. A complete list of specifications and special equipment is included. Copies of this book may be secured from the local dealers, or by writing the manufacturer. If requesting a copy of this book, kindly mention our publication.

Paver.—The Ransome Concrete Machinery Company of Dunellen, N. J., has just issued a very handsome, fully illustrated 36-page book, called "The Master Paver." A complete description is given of the Power Loader, Water Control, Drum, Drum Rollers, Discharge, Boom, Boom Bucket, Supporting Frame, Operating Levers, Engine, Gears, Shafts, Clutches, Main Frame, Crawler, Crawler Drive, Derrick, Distributing Chute and Calcium Chloride Attachment. Important parts are clearly shown in photographs, and pictures of the paver at work on specific jobs are shown, and names of the owners given. The book contains diagrams and specifications of the new Ransome 27-E, and one section is devoted to "Central Mixing Plants." If writing the manufacturer for a copy of this book, kindly give the name of our publication.

Pipe Cutting Tool.—A folder from the Tucker Company, Inc., 75 Murray Street, New York City, gives a detailed description and price list of parts in all sizes of their cutter for cast iron pipe. This tool can be used in any ordinary trench without extra excavating. It will cut a piece one inch long or more at any point without starting joints or otherwise disturbing the main, and will make a clean cut in a gas or water main in the trench. Write to the Tucker Company for literature and price list of the Anderson Pipe Cutting Tool. In writing, kindly give the name of our magazine.

Water Level Indicators — Weather Gages, Etc.—Several pamphlets have been received from Julien P. Friez & Sons, Baltimore, Maryland, devoted to their recorders, indicators and air gages. In the Airport Bulletin two outfits are described. For large airports a complete set of instruments for observing meteorological conditions is offered. In addition to permitting visual observation of all local weather conditions, this equipment records these conditions graphically on charts. A complete picture of the weather is thus furnished. Equipment No. 2 is an economical combination of instruments for airports when complete meteorological records are not desired. The Bulletin "Telaugage" describes the Au Water Level Indicator for remote indications of levels of all impounded and flowing waters. The development of the self-synchronizing electric motor has made possible the accurate transmission of this information automatically and its reproduction, several miles away if necessary, on dials graduated to show changes as small as one-hundredth of a foot. For literature on these Recorders, Indicators and Airport instruments write Julien P. Friez & Sons, Baltimore, Md., mention our publication.

Electrical Testing. — The Wagner Electric Corporation of St. Louis, Missouri, has just issued the fourth edition of its bulletin on Manual of Electrical Testing, a 20-page bulletin on testing single phase and polyphase motors, and testing transformers for core loss, copper loss, polarity, insulation, temperature rise and efficiency. This is a loose leaf style bulletin suitable for binding with other literature. The bulletin gives the addresses of the offices of this corporation located in all the principal cities from coast to coast. If writing for a copy of this particular bulletin specify No. 138. We would appreciate it if you would give the name of our magazine.

Municipal Refuse Incinerators.—The Hiler Engineering & Construction Co., Inc., 122 Livingston Street, Brooklyn, N. Y., has issued a very attractive little 24-page booklet on the Heenan System of Municipal Refuse Incinerators. This system of municipal waste disposal was made the recognized standard in the United States in 1906 after one of the most exhaustive studies of the problem had been made, covering existing plants in this country and abroad. Illustrations and descriptions are given of the plants in use in the

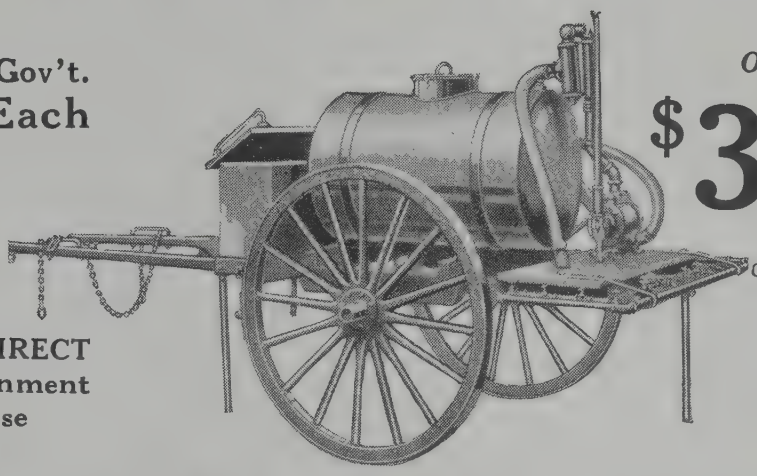
U. S. GOV'T. WATER CARTS At a Give-away Price

Cost U. S. Gov't. $275.00 Each



ONLY

$37.50

F. O. B. Columbus, Ohio

Horse Drawn

Shipping Weight 1600 Lbs., Crated

SHIPPED DIRECT From Government Warehouse

A Cart With Many Uses

These Water or Tank Carts are part of the U. S. Gov't surplus stock—they are brand new, have never been used—cost $275.00 each and we now offer them to you at the almost give-away price of only $37.50.

Think of it!—a 150 Gallon, Heavy Gauge Galvanized Iron Tank Cart, equipped with Double Acting Gould Force Pump—25 ft. of 2″ hose—16 Brass Faucets, etc. Strong, Sturdy 54″ Wheels, Steel Hubs and Axle—for less than 1/6 what the Government originally paid for them!

These Carts are horse drawn—and make the ideal equipment for sprinkling walks or roadways—for sprinkling and spraying flowers, trees and shrubbery—for hauling water, gasoline or oil—a real handy utility Tank Cart with dozens of uses.

Send us check or money order for $37.50 and we will send you one of these Water Carts, in its original crate, just as it was delivered to the U. S. Gov't by the Studebaker Wagon Works or other high grade manufacturer who built it.

Note These FEATURES

Made for the U. S. Gov't by the Studebaker Wagon Works and other high grade Wagon Builders. Never used—comes to you in original crates just as delivered to the U. S. Gov't Warehouse. A mighty useful and handy outfit. Tank is of heavy gauge one-piece galvanized iron, with splash partitions, solid riveted joints, capacity 150 gallons, Gould Double Acting Force Pump, extra large strainer—25 ft. of 2-inch hose (we do not guarantee condition of hose, yet it may give considerable service); wheels 54 inches in diameter, 3-inch steel tires, 10-inch steel hubs; tread 56 inch, steel axle 2x2 in.; foot brakes, tool box under seat; 15 brass faucets in rear for drawing off contents and one extra large master faucet.

For Spraying

Easily converted into a sprayer. By making a few changes in the pipe connection, this outfit can be converted into an air pressure sprayer worth at least $300.00. Instructions sent with each cart.

Guaranteed Exactly as Represented

You take absolutely no risk in ordering these carts. The publishers of this paper have inspected these Carts and know the splendid value represented in these carts and the opportunity for its subscribers to get the greatest Bargain ever offered. Remember, these carts have never been used—come to you just as delivered to U. S. Government. They are EASILY WORTH SIX TIMES THE PRICE WE ASK.

We can't begin to tell you in this ad the wonderful value represented in these Tank Carts—they must be seen to be appreciated. We do know that after you get one, you wouldn't sell it for several times the low price you paid for it. Many who have ordered one, after receiving it and seeing its splendid value and the many uses to which it could be put, have immediately ordered from one to three more. Send your order now.

National Jobbing & Export Co. Dept. Z, 192 N. Clark St. Chicago, Illinois

principal cities. At Buffalo, N. Y., is the largest incinerator plant in this country which represents the latest type of the Heenan System and which has the most complete and effective equipment for the handling and destroying of 500 tons of Mixed Garbage and Rubbish in 24 hours. Write for literature on this system.

Western Hot Patch Plant.—A product of the Austin-Western Road Machinery Company, 400 North Michigan Avenue, Chicago, for keeping roads in repair winter and summer. Write to their Chicago office or any branch office for their Bulletin on Winter Repair Work for particulars concerning this equipment. We would appreciate it if you would mention our magazine.

Cast Iron Pipe.—The McWane Cast Iron Pipe Company of Birmingham, Alabama, will be pleased to send upon request, illustrated literature giving full information concerning their product, its cost, life and uses. The western branch of this organization is the Pacific States Cast Iron Pipe Company of Provo, Utah.

Aerator.—The Simplex Surface Aerator, an effective means of producing "activated Sludge," is fully described in Bulletin E-5-28, issued by the Simplex Ejector and Aerator Corporation. The Chicago address is 2528 W. Madison St., Chicago. If writing for literature, kindly mention our magazine.

Automatic Air-Lift. — The Sullivan Machinery Company, 130 South Michigan Avenue, Chicago, has a handbook on their automatic air lift, and special automatic control information of particular interest to water works superintendents. Their catalogs also describe air made wells, and contain a complete story of how a city elected a mayor on his promise to get them well water, and how his promise was kept by the use of this method. Kindly mention our publication when requesting catalogs.

Layne Well Systems. — Write to Layne & Bowler, Inc., Memphis, Tenn., for information concerning their guaranteed pumps and screens. We would appreciate if it you would use the name of our paper if writing for particulars.

Wrought Iron Pipe.—"The Installation Cost of Pipe" is the title of a Bulletin issued by the A. M. Byers Company, Pittsburgh, Pa., containing cost data and full particulars concerning this product and its uses. Ask for Bulletin No. 38, giving the name of our magazine.

Trimo.—The trade name by which the wrenches manufactured by the Tremont Manufacturing Company, Inc., are known. These pipe wrenches are made with a braced frame to stand the hardest strain, with hard biting jaws that can be easily renewed, and the heat treated steel handles assure tremendous strength. Write for detailed information and prices to Roxbury (Boston), Mass., mentioning the name of this magazine.

Gate Valves.—The Darling Valve & Mfg. Company, with offices in New York, Chicago, Houston and Oklahoma City and headquarters in Williamsport, Pa., will be pleased to send you literature on the construction and operation of the Darling Gate Valves. If writing for particulars on this product, kindly mention our paper.

Deep Well Works.—The United Iron Works, Inc., of Springfield, Mo., with general offices in Kansas City, manufacturers of "Pomona" double stroke deep well power pumps, offer without obligation methods for economically solving pumping problems. The engineering experts will be pleased to advise with you. Descriptive catalogs will be sent upon request. If writing, kindly give the name of our magazine.

Pumps. — New Catalog containing complete information on centrifugal pumps, plunger pumps, and deep well power heads may now be obtained by writing the American Well Works, Aurora, Illinois. Their engineering department will be pleased to discuss your needs with you, recommending the best equipment for your purposes. Kindly use the name of our publication if writing for information.

Mono-Cast Pipe. — The trademark name of the American Cast Iron Pipe Company for a centrifugal cast iron pipe made in a refractory mold, was chosen because only one second is required to transform the molten metal into pipe by this method. Write to the Birmingham office of this company, or to their branches in the principal cities for literature on this product. Ask for information on Mono-Cast Cast Iron Pipe, giving the name of our magazine.

Disposal Plants. — Fairbanks-Morse and Co., Chicago, or any of their branch offices in the principal cities will be pleased to furnish complete details concerning their F-M Trash pumps for handling unscreened sewage direct from sewers. Write for information, giving the name of our publication.

Excavators.—Write to the Bucyrus-Erie Company at Erie, Pa., or to their branches in any of the principal cities for information concerning the performance of their excavating machines. This will give you a gauge by which to measure the work you are now able to do, with the records of other equipment.

Ejectors.—The Shone Sewage Ejectors, manufactured by Yeomans Brothers, 1423 Dayton Street, Chicago, are in use in all quarters of the globe with long service records to their credit. Write to this company for literature giving the special features which enter into the merits of this equipment.

Cast Iron Pipe.—"The Two-Main System" is the title of a book which The Cast Iron Pipe Research Association is distributing free to city officials, engineers and taxpayers. It is a pocket size volume, written in non-technical style, with charts, drawings and photographs to make the telling more forceful. It explains how the two-main system is able to meet the demand of the taxpayer for a means of preventing the tearing up of costly streets for extensions, repairs, etc. A valuable book for public officials and engineers. Write to Mr. Thos. F. Wolfe, Research Engineer, Peoples Gas Bldg., The Cast Iron Pipe Research Association, for a copy of this book, kindly mentioning the name of our paper.

Clay Pipe.—The Clay Products Association, Conway Building, Chicago, makers of vitrified clay pipe, will be pleased to send you full information regarding this product.

Meters — Gauges — Valves. — Information on complete equipment for filtration plants may be secured by writing the Simplex Valve & Meter Company, 6749 Upland Street, Philadelphia, Pa. The Simplex Rate of Flow Controller is adaptable to large and small filter plants from 30-inch effuent to 3-inch. The Simplex Venture Type Meter indicates, records and totalizes the rate of flow, and the Simplex Filter Gauges may be had in many combinations of Indicating, Recording and Totalizing. If writing for particulars on this equipment, kindly mention our magazine.

Filtration Plants.—Norwood Engineering Company, Florence, Mass., will be pleased to send you full particulars regarding the Norwood Municipal Filtration Plants. Kindly give the name of our publication if requesting information.

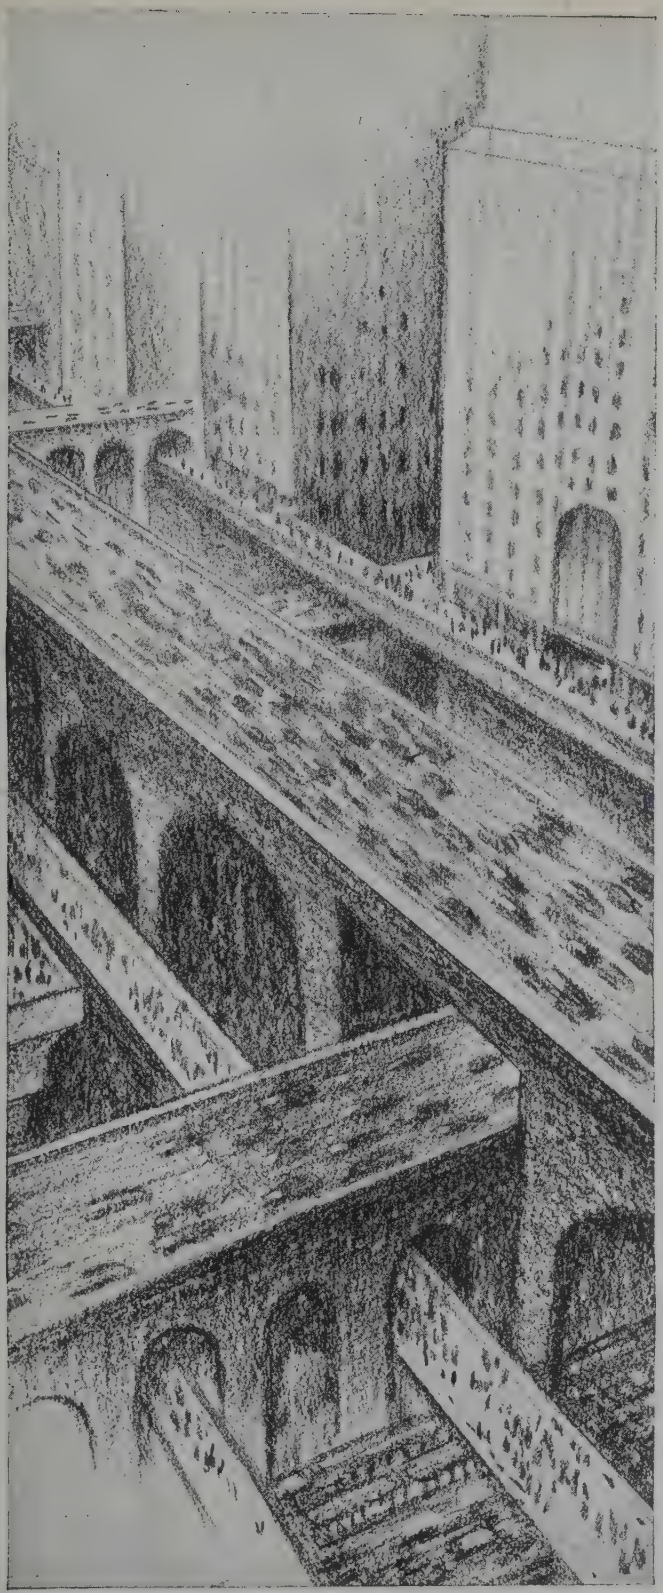
Steel Tanks.—A new Water Works Catalog has been issued by the Pittsburgh-Des Moines Steel Company, 906 Tuttle St., Des Moines, and 4 Neville Island, Pittsburgh, Pa., with branches in the principal cities. These elevated steel tanks insure a large supply of water at any and all times. If desiring information, ask for Catalog No. 2, kindly giving the name of our magazine.

Pipe Cutter.—Manufactured in two sizes for all types of pipe by the Ellis & Ford Mfg. Co., 18 Piquette Ave., Detroit, Mich. Circular giving full particulars will be sent by manufacturer upon request. We would appreciate it if you would mention our magazine, if writing.

Meter Boxes.—The Ford Meter Box Company of Wabash, Indiana, have a special bulletin on the Ford Type S Meter Boxes for "warmer climates." Meters can be set or removed in an instant. The Ford standard testers can be adapted for testing meters in a series, each meter clamped in separately and the work economically and conveniently handled.

Centrifugal Pumps. — Catalog-W-67

(Continued on page 44)



FOR CITIES WHICH LOOK 100 YEARS AHEAD

CITIES looking a century ahead are planning to meet problems undreamed of a decade ago. Problems involving underground and surface transportation . . . . pedestrian and motor traffic . . . . the interlocking problem of proper gas and water systems.

The streets of the future need never be torn up for pipe replacements. For cast iron pipe may be laid and forgotten. Cast Iron pipe's full span of life has never been measured. Mains that have served a century, two centuries, and longer, are still in service.

Cast Iron Pipe made by the members of The Cast Iron Pipe Research Association is manufactured under laboratory control to the modern standards of the Association members. The Association offers to taxpayers, city officials and engineers, information on every subject pertaining to the use of pipe for water, gas, sewers, road culverts and for industrial needs. All information is supplied without cost or obligation. Address: Thomas F. Wolfe, Research Engineer, Peoples Gas Building, Chicago.

CAST IRON PIPE

issued by DeLaval Steam Turbine Co., Trenton, N. J., gives methods of meeting water supply problems at the lowest cost. Full information regarding geared steam turbine driven pumps, electric motor driven pumps or internal combustion engine driven pumps. If writing for a copy of this booklet, kindly give the name of our publication.

Hydraulic Supplies.—Write to the Reading Meter Repair Company, Inc., Reading, Pa., for prices and particulars regarding testing or repairing water meters, using the name of this magazine.

Air Pump.—The Indiana Air Pump Company of Indianapolis, Ind., will be pleased to send upon request a catalog giving details regarding construction and operation of air-lift method of pumping wells. If writing this company, kindly give the name of our publication.

Porous Concrete Well.—Upon receipt of a request E. Thorpe, 1932 Illinois Avenue, East St. Louis, will send you a folder describing the advantages of the porous concrete well. With this information they send a list of satisfied users of this type well.

Force Pumps.—Bulletin 28-MF has just been issued by the Domestic Engine & Pump Co., Shippensburg, Pa., giving specifications and types of their pressure force pump units.

Adensite.—A liquid integral compound used in the gauging water for Portland cement concrete and mortar, is described in a folder recently issued by the Adensite Co., Inc., 116 West 39th St., New York. The folder contains many illustrations showing where the product has been used, and a list of buildings where installations have been made. Write for full particulars concerning this product to the manufacturer, giving the name of our magazine.

Sanitary Specialities.—Manufactured by the Servicised Products Corporation include Bituminous rope, sewer compound and sewer belts (both acid and root proof), and asphalt liner slabs, proof against sewer liquors. Illustrated literature giving complete descriptions and details concerning these products for obtaining permanently tight and lasting sewers will be sent upon request by the Servicised Products Corporation, 6051 West 65th Street, Chicago, Ill. If you will mention our publication when writing to Mr. A. C. Fischer of the Servicised Company for this information it would be greatly appreciated.

Moir-Buchanan Centrifugal Process.—This process is to obtain high density, low absorption and long life of concrete pipe. Rights to use this process may be secured through the Asphalto-Concrete Corporation, 1440 Broadway, New York City. If interested in learning about this process and how strength and durability are secured by this method write to Mr. Geo. H. Schroder of the Asphalto-Concrete Corporation, using the name of our magazine and ask for full particulars.

Chlorinator.—Bulletin W-21 issued by the Paradon Manufacturing Company of Arlington, N. J., describes in detail the Paradon Chlorinators for city and private water and sewage systems, industrial plants and swimming pools. If writing for this bulletin address Mr. R. V. Donnelly, care of the manufacturer. We would appreciate it if you would mention our publication.

Centrifugal Pumps.—In order to be of assistance to users in choosing the right pump for their needs, Bulletin 1632-I has been issued by the Allis-Chalmers, Milwaukee, Wis. Types for steam turbine drive, motor drive or gasoline engine drive are described to best fit the purposes of installation. Write to Mr. H. G. Hoffman for copy of this bulletin, mentioning Municipal News and Water Works.

Dragline.—Write to Koehring Company at Milwaukee, Wis., or to any of their branches in the principal cities, for Dragline Bulletin DL9. The ease of control and speed in functioning are important features of this heavy duty Koehring equipment. Mr. O. C. Dahlman will furnish bulletin on request. If writing mention our magazine.

Cast Iron Pipe.—James B. Clow & Sons, 201-299 North Talman Avenue, Chicago, with foundries at Coshocton, Ohio, Newcomerstown, Ohio, and Birmingham, Alabama, carry large stock of pipe at points where large supplies can be obtained on short notice. Wire or write them concerning your requirements, they will be glad to care for your needs without delay. Mention our magazine when writing this company.

Cast Iron Pipe.—The Central Foundry Company, manufacturers of cast iron pipe with offices located in the principal cities, will be pleased to have you call at the nearest office or write to the New York office, 420 Lexington Avenue, for complete information in regard to their product, an iron to iron joined pipe, allowing for expansion and contraction, vibration and uneven ground settlement. Used for water supply, fire protection and other service.

Hydrants and Valves.—The Mathews Fire Hydrants, built for easy installation and so that an extension section may be used to adapt them to new grades, are described in literature of the R. D. Wood & Co., Philadelphia. If you will write to Mr. C. Becker of this company he will gladly send you full information about their sand-cast and "sand-spun" centrifugal cast iron pipe fittings, valves, boxes and hydrants. Please use the name of our magazine if writing.

Lubricant.—The Dot Lubricant Equipment Company, Division of the Carr Fastener Company, Cambridge, Mass., has issued a unique little folder called "Little Journeys in Dot Lubrication," illustrating and describing the various steps in the use of this lubricant. The trip described is that of taking the grease from the storage tank to the bearings quickly, comfortably for the user, absolutely free from dust and dirt.

Meters.—The Union Water Meter Company of Worcester, Mass., with offices in New York City and Philadelphia, will be pleased to send you literature concerning their King Frost Protected Meter, built to overcome every known weakness in frost meter design. If interested in meters of this type write to Mr. E. K. Otis for full particulars. We would appreciate it if you would mention this publication.

Valves.—Golden-Anderson Valve Specialty Company located in the Fulton Building, Pittsburgh, have issued a descriptive and data catalog on their automatic valves for steam and water service. Full details are given on each page as to construction, operation variations together with cross-section drawings. Data required for ordering is made very clear. If you desire a copy of this catalog write to Mr. J. A. Voland of the Golden-Anderson Company mentioning the name of our magazine.

Francois Cementation Process.—The Dravo Contracting Co. have acquired the sole American rights to the Francois patents, and have a highly skilled staff who will be pleased to help you with your problems. This method of grouting covers chemical processes for a hundred and one different cases, the engineers of the Dravo Company are ready to help you solve your problems. Write to their company at Pittsburgh, Pa., mentioning our magazine.

Hydrants, Valves, etc.—Full particulars for supplies needed by water works and fire departments will be sent upon request by the Bourbon Copper & Brass Works Co., 618 E. Front St., Cincinnati, Ohio, manufacturers of fire hydrants, gate valves, and extension valve boxes. Write for their catalog, giving the name of our magazine.

Sewer Cleaning Machine.—W. H. Stewart, whose factory is at Walkerville, Ontario, has branches in St. Louis, Mo., Jacksonville, Fla., and Boston, Mass., so that his patrons on this side of the border may be served without paying duty. Literature describing his sewer and conduit rods will be furnished on request. Rods will be shipped on trial. If writing to Mr. Stewart for information concerning his equipment kindly mention our publication.

Zeolite.—"Softening Municipal Water Supplies by the Use of Zeolite" is the title of a bulletin issued by the Zeolite Chemical Company, 140 Cedar Street, New York City. This booklet describes Green Sand, a natural base exchange Zeolite Mineral, used for the purpose stated. Write to Mr. R. E. Wagner of the Zeolite Company for a copy of this bulletin. If writing, we would appreciate it if you would mention this magazine.

(Continued on page 46)

THE durability and economy of highways surfaced with Stanolind Cut-Back Asphalt has been well demonstrated on many roads throughout the Middle West.

Main Street at Hutchinson, Minn., was surfaced with Stanolind Cut-Back Asphalt, using 3/10 of a gallon per square yard, and 20 pounds of Torpedo Gravel per square yard. Roller was used to surface.

Manhole and Catch Basin Covers.—Write to Wm. E. Dee Company, 30 North La Salle, Chicago, Ill., for particulars concerning the different types of manhole and catch basin covers. Prices will be included on request. If writing, kindly use the name of our magazine.

Chlorination.—Wallace & Tiernan, Newark, New Jersey, manufacturers of chlorine control apparatus will be pleased to send you full particulars in regard to the sterilization of water by their method, and to furnish you with record of cities where their apparatus is being used. If writing for information, we would like to have you mention our magazine.

Rayflectors.—The trade name of patented reflecting devices designed for utilizing light from automobile headlights, or other outside sources, to make signs and signals visible at night. The Rayflectors are manufactured by the Ray-Signs Corporation, of New Haven, Connecticut, and are described and well illustrated in a very attractive, well bound, 12-page booklet. These devices come in three sizes and in white, red, green and amber. This black and gold booklet will be sent upon request by the manufacturer, and we would appreciate it if you would mention our publication when writing.

Lubrication.—The story of the Alemite Manufacturing Corporation system of lubrication issued in magazine style. This pamplet, Lubrication Maintenance, is published in the interest of better industrial lubrication and lower production costs, and will be mailed free to any one interested. If writing for this booklet, will you kindly mention our publication? The address of the Alemite Manufacturing Company is 2646 North Crawford Avenue, Chicago.

Valves.—The Darling Valve & Mfg. Company with offices in New York, Chicago, Houston and Oklahoma City and headquarters in Williamsport, Pa., will be pleased to send you full information in regard to the design and performance of their valves which are built to minimize friction and wear. If writing for literature to Mr. A. G. Smith at the Williamsport office of the company, kindly use the name of our magazine.

Bags.—Let the Bates Valve Bag Corporation, 35 Wacker Drive, Chicago, tell you about their multi-wall-paper bags in a very attractive folder which they have recently issued. These bags are proving of inestimable value to the contractor in protecting his plaster from losses by the elements. This company also manufactures the Bates Ties and Tools for the use of contractors in speeding up reinforced concrete work, by fast, tight, non-slipping ties requiring no special skill to apply. Write to this company for their latest literature, mentioning the name of our publication when writing.

Electric Power.—A very attractive forty-eight page booklet, well bound and profusely illustrated, is now being distributed by the Electric Machinery Manufacturing Company of Minneapolis, Minnesota. It is devoted to the subject of power factor correction with capacitors (static condensers). The title of the book is "Reducing the Cost of Electric Power" and gives a non-technical explanation of power factor and shows when and how to apply capacitors to reduce electric power cost. It also explains the construction of capacitors. This company has offices in all the principal cities where copies of this book may be secured, or from their main office at Minneapolis.

Dredges.—Catalog E issued by the Norbom Engineering Co., Darby, Pa., gives full particulars concerning the Norbom Hydraulic Dredges. These dredges will be built to suit your special requirements. Write for a catalog giving the name of our magazine.

Inertol.—This is a waterproofing and anticorrosive compound for impregnating concrete surfaces and for protecting steel, making the structures waterproof under pressure and immune against aggressive chemicals. This is manufactured by the Inertol Company, Inc., 253 Broadway, New York City, and stocks are carried in Newark, N. J., Chicago and San Francisco. In color it is a glossy black and comes ready for use, and needs no skill in applying, but is used cold with brush or paint sprayer. An illustrated broadside has just been received from this company giving the many uses for this product, prices, etc. Write to the manufacturer for full information, mentioning this magazine.

Meter Testers.—A catalog giving complete information on the Mueller Meter Tester will be sent upon request if you will write to Mr. C. N. Wagenseller of Decatur, Illinois, mentioning this publication, or they may be secured at any of the branch offices of this company. The Mueller Meter Testers are simple of operation and of a lasting quality of construction. Statistics show that meters under-register oftener than they over-register and an accurate meter tester insures honestly earned revenues. Meters should be tested before installation and at regular periods thereafter. The Mueller catalog will give you complete information on this subject.

Hydraulic Dredge Capacity Indicator.—The Ellicott Machine Corporation, 1111 Bush Street, Baltimore, Maryland, specialists in dredging outfits, are equipped to furnish you with well designed hydraulic dredge, either diesel, electric, gasoline or steam driven, built for efficient and economical service. Mr. C. E. Ellicott, Jr., will be pleased to furnish you full information concerning outfits for jobs of all sizes. If you will mention this magazine, he will send for your convenience a hydraulic dredge capacity indicator.

Governors.—How to increase production and profits and lower operating costs, by the use of Pierce Governors, is described in Booklet No. 14, issued by the Pierce Governor Company, of Anderson, Indiana. This equipment on power engines results in a smooth, uniform flow of power to meet every load. Fuel, operating and repair bills are reduced and the life of engines prolonged. Mr. D. J. Nolan, of the Pierce Governor Company, will be pleased to send you a copy of this booklet, and we should be pleased if you would mention our magazine when writing.

Portable Compressors.—Ingersoll Rand Company, 11 Broadway, New York City, will be glad to send you catalog describing their gasoline engine or electric driven portable compressors in six sizes. If writing for this information, will you please mention our magazine.

Steel Sheet Piling.—Lackawana Steel Sheet Piling, particularly suitable for the long sea wall. For information regarding this product write to the Bethlehem Steel Company, Bethlehem, Pa. Mr. S. H. Yorks is sales-manager. In writing Mr. Yorks, give the name of our magazine.

Pumps, Engines, Hoists.—If you have hoisting problems, write to Mr. Clarence E. Bement, of the Novo Engine Company, 200 Porter Street, Lansing, Michigan, asking for a free copy of Novo Hoisting Handbook. This is not a catalog but a book of useful information for the man who must meet hoisting problems. They will also be glad to send you full particulars concerning their entire line of products.

Lumber.—For the users of lumber the National Lumber Manufacturers Association, Transportation Building, Washington, D. C., has much valuable information in booklet form, which they will be glad to send you. Bulletin No. 16 is called "Simplified Practice" and another booklet containing much general information is called "Information on Lumber and Where to Find It." Either of these booklets will be sent without obligation by addressing the company at Dept. 4651, at the address given above. If applying for a copy kindly use the name of our magazine.

Water Softeners.—The International Filter Company, 333 West 25th Place, Chicago, present in an illustrated bulletin Crystalite, a water softening product. This is an attractive 16 page booklet, well printed on heavy enamel paper. It discusses the chemistry of zeolite water softening; the early history and development of zeolites; Crystalite as a super rapid zeolite; the advantages of upflow softening illustrated with curves. Crystalite Water Softeners installed by the International Filter Company are illustrated, and special industrial uses for Crystalite are listed. If writing for this bulletin, kindly mention our magazine.

"ACIPCO" Products Are All *Quality*  *Checked*

As one of the pioneer pipe founders who helped establish modern standards of cast iron pipe manufacture—affiliated with the Cast Iron Pipe Research Association—this company will hereafter emblazon all of its products with the "Q-check" trade mark of that Association.

This "Q-check" mark appearing on our pipe is but a new, outward symbol of that old, inherent quality which has characterized Acipco products for a quarter century.

Tens of millions of feet of our pipe are now in service. The men who laid this tremendous footage have already checked our products for quality. To these we present this "Q-check" mark as a guarantee of continued satisfaction. To those who have never used our pipe, we offer this "Q-check" mark as an official endorsement of our products. To all concerned with the use of pipe for water, gas, sewers, road culverts, etc., we submit this reminder: Don't forget to look for the "Q-check" mark and you can forget the pipe after you've laid it!

The symbol shown above has been adopted as a trade mark by the Cast Iron Pipe Research Association with which this company is affiliated. Insist on the "Q-check" mark when specifying cast iron pipe for gas, water, sewer, or industrial use.

DISTRIBUTOR NEWS

The Distributor's Department in the Gillette Construction Group

Station GCG

This is the Gillette Construction Group broadcasting from our headquarters in Chicago, the news and views of distributors and manufacturers in the field of construction engineering. Every month 70,000 receiving sets throughout the world, made up of 27,000 readers of Engineering and Contracting; 27,000 readers of Roads and Streets, and 16,000 readers of Municipal News and Water Works are able to enjoy these tri-monthly broadcasts, which are sent to them through the interest and courtesy of makers and distributors of all kinds of equipment machinery.

Distributors and manufacturers in all lines of construction engineering products have served as announcers over this station. We want them to continue to let us hear from them. There are many more with interesting stories to tell who have not yet been heard over GCG. Just send your items and pictures to The Editor, Distributor News, Gillette Publishing Company, 221 E. 20th St., Chicago, and they will be broadcast over Station GCG, which has no wave length limit. Please stand by for Distributor News items coming through GCG March issue of Municipal News and Water Works.

Ashcraft Is Sauerman Representative

Since last December the sale of Sauerman equipment in western Pennsylvania and the adjoining border counties in Ohio and West Virginia has been handled by Charles E. Ashcraft, 335 Fifth Ave. (the State Theater Building), Pittsburgh.

Mr. Ashcraft, formerly engineer and salesman for the Beckwith Machinery Company, has designed plants and furnished equipment for hundreds of contract jobs and industrial projects in the district. He had charge of many Sauerman installations made by the Beckwith Company so is well informed on their slackline cableways and power drag scrapers.

He is a native of Kentucky and holds a civil engineering degree from the University of Cincinnati. Before taking his degree he had much experience in practical engineering, such as surveying, architecture, building construction and railroad engineering. He has worked with the United States Engineers on the design and construction of works of navigation, as superintendent of construction with the Foundation

Charles E. Ashcraft

Company, and as general superintendent of construction for the Baker-Dunbar-Allen Company.

He has been identified with many important slackway water developments and the operation and care of works of navigation on the Monongahela River. New Lock No. 4, Monongahela River, which was probably the most important work of which he had charge, now has the distinction of passing more tonnage than any lock in the world, except the locks at Sault Ste. Marie, Mich.

After many years spent in contracting work, during which time Mr. Ashcraft engaged in building various kinds of structures such as retaining walls, docks, trestles, coal tipples, water intakes, pump pits, etc., he decided to abandon the roaming life of a construction man and naturally turned to the field of selling construction equipment. So it happened that he joined the Beckwith Machinery Company at a time when they were establishing advisory engineering service for the benefit of their contracting and industrial clientele. This consultation work with contractors and engineers, involving the designing of all kinds of structures, required a theory and practice in a field of engineering construction which Mr. Ashcraft's wide experience enabled him to bring to it.

The fact that the Beckwith Company has withdrawn from the sale of Sauerman equipment, owing to a desire to concentrate largely on the sale of tra tors and tractor auxiliary equipme was the reason of Mr. Ashcraft's resi nation from that company and his a rangement with Sauerman Bros., I He will now devote his entire time Sauerman equipment. His services c be of great benefit to aggregate pr ducers, industrial plants, contracto and other users of slackline cablewa and power drag scrapers, for his expe ence makes him familiar not only wi the details of applying this equipme but also with the many other proble with which these clients are co fronted.

H. W. Moore Equipment C Establish Wyoming Branch

The H. W. Moore Equipment C of Denver, Col., well known distri utors of construction and road buil ing machinery, have recently organiz a company under the laws of the Sta of Wyoming, to be known as the H. Moore Equipment Co. of Wyoming.

The new company, which is locat at 421 W. 17th St., Cheyenne, will under the management of Mr. John Wortham, who is also treasurer of t company. Among the lines which w be represented in Wyoming are: Gali leaning and straight wheel grade road rollers and maintainers; Ced Rapids crushers, screens and conveyo Schramm compressors; Jaeger concre mixers; General excavators; Mari steam shovels; Lakewood grade ro ers, concrete and asphalt finishers a clamshell buckets; Baker snow plo and maintainers; Wehr "One Ma power maintainers; Chausse asph and tar heating equipment; Super S ney steel plows, fresnos, slips; Atl conveyors, etc.

The officers of the H. W. Moo Equipment Co. of Wyoming, Inc., a Mr. George L. Meffley, president; J. Moore, vice-president and secreta and J. R. Wortham, treasurer.

Mr. Moore states that the reason f starting a branch in Cheyenne is b cause they believe the development the State of Wyoming now justifi such a venture and that results, so f have been very satisfactory. Until t year, Mr. Moore says, there has be no equipment house in the state. small stock of equipment and repa will be carried in Cheyenne, which w assure service to the Cheyenne cu tomers.

CAST IRON PIPE

THE symbol shown above has been adopted as the trade mark of The Cast Iron Pipe Research Association. Cast iron pipe with age-defying qualities acknowledged for generations, plus the improvements which scientific research has introduced, can hereafter be identified by this symbol. It will appear on cast iron pipe made by the leading pipe founders listed below. Insist on the "Q-Check" mark when you buy cast iron pipe, whether for gas, water, sewer, or industrial service.

The Cast Iron Pipe Research Association is a service organization of leading pipe founders, formed to promote the scientific improvement and proper use of cast iron pipe. Pipe bearing the "Q-Check" mark may be obtained from the following: American Cast Iron Pipe Co., Birmingham, Ala.; James B. Clow & Sons, 219 N. Talman Ave., Chicago, Ill.; Donaldson Iron Company, Emaus, Pa.; Glamorgan Pipe & Foundry Co., Lynchburg, Va.; Lynchburg Foundry Company, Lynchburg, Va.; National Cast Iron Pipe Company, Birmingham, Ala.; United States Cast Iron Pipe & Foundry Company, Burlington, N. J.; Warren Foundry and Pipe Company, 11 Broadway, New York City.

The Cast Iron Pipe Research Association, Thomas F. Wolfe,
Research Engineer, Peoples Gas Building, Chicago.

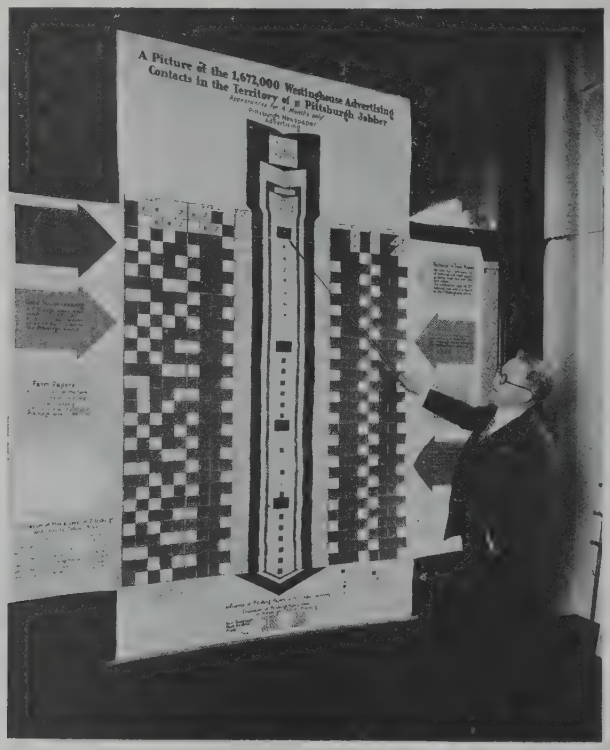
Westinghouse Increases Advertising Program In Techanical Journals

According to a statement issued by Mr. J. C. McQuiston, general advertising manager of the Westinghouse Electric and Manufacturing Company, a greatly expanded program of advertising for 1929 in the technical, trade and business publications has been decided upon.

"The increase," states Mr. McQuiston, "in the number of products from year to year which we manufacture has made it advisable for us to change our technical advertising to keep step." He believes that leading industries offer a market for a large number of Westinghouse products, and it is the plan to use group advertisements to call to the attention of executives in an industry, the whole line of equipment suitable for that industry. The story of Westinghouse service will be emphasized in a series of messages presented in technical magazines.

The aim of the advertising policy for expanding the electrical industry, as outlined by Mr. McQuiston, is to educate the public concerning the vital part that electricity plays in modern civilization, and to cooperate directly with distributors of electrical products in advertising programs, as a direct service to distributors.

The field of advertising media to be used, includes business and technical magazines, farm papers, financial publications and school and college papers. For general institutional and consumer advertising continued use will be made of newspapers on a considerably expanded scale. An interesting feature mentioned in connection with the plan for the use of newspapers is the Sunday rotogravure advertising, which up to this time has never been used for this purpose.



J. C. McQuiston, General Advertising Manager of the Westinghouse Electric and Manufacturing Company, Perfects New Form of Chart by Which He Knows in Detail Months in Advance Where Each Advertisement Will Appear and at the Same Time Has a Complete Picture of His Entire Campaign Before Him. This Chart Was Prepared for Use in the Westinghouse Company's 1929 Advertising Program.

T. W. Rosholt Company To Handle Tracksons

Trackson Tractor Equipment for the McCormick-Deering Industrial Tractor will be represented in the north central section of the country by Thorman W. Rosholt Company, 928 S. Fourth St., Minneapolis, according to an announcement of the Trackson Company, Milwaukee, Wis.

The territory to be represented by the Rosholt Company includes Fargo and Grand Forks, N. D.; Winona, St. Cloud, Minneapolis and Mankato, Minn., and Eau Claire, Wis., where the International Harvester Company maintain branches.

Stocks of Trackson full-crawlers, loaders, shovels, cranes, bulldozers, etc., will be carried, as well as repair and replacement parts.

New Department Manager For H. O. Penn Machinery Co.

Mr. M. V. Rider, formerly New York sales manager for the T. L. Smith Company, has joined the H. O. Penn Machinery Co., of New York, as manager of their road building department. He will handle the sales of all road construction equipment for them.

George Haiss Mfg. Co. Announces New Distributors

The Equipment Company of Boston, Mass., has been made distributor for the George Haiss Mfg. Co., Inc., New York, for eastern Massachusetts, Rhode Island and the southeastern part of New Hampshire.

The northern and eastern parts of Florida will be covered for the Haiss Company by the Coulter-Hart Equipment Company, of Tampa, Fla.

W. C. Caye & Company Will Represent Erie Machine Shops in Georgia

Announcement is made of the appointment of W. C. Caye & Co., 158 Walker St., Atlanta, Ga., as distributor for the Erie Machine Shops, Erie, Pa., manufacturers of Erie steam and gasoline rollers.

Trimont Mfg. Company Makes Purchase

The Trimont Mfg. Co. of Roxbury, Boston, Mass., has purchased the Stillson wrench business of the Moore Drop Forging Company of Springfield, Mass., and will continue the manufacture of both the Original Pattern and Popular type Stillson wrenches.

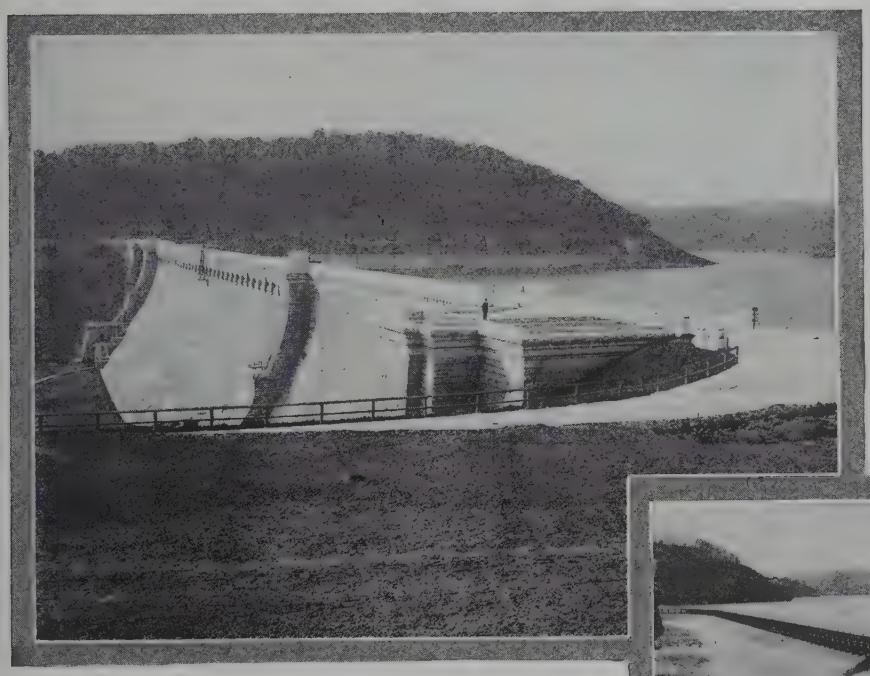
The Morco Original Pattern Stillson will, under Trimont manufacture, be known as SANDO Original Pattern Stillson and the Marco Popular will hereafter be known as MOROCO Popular.

All of the Trimont Company's 40 years' experience in the making of fine tools goes into the forging, hardening and other manufacturing processes of these Stillson wrenches and both will compare favorably in quality and price with other Stillsons of their type now on the market.

The Dow Chemical Company of Midland, Mich., announce the appointment of Mr. Donald Williams as assistant sales manager to succeed Mr. S. W. Putnam, whose resignation was accepted in December.

MILLIONS WERE SPENT

to construct this New York Water Supply System



Croton Dam and Spillway, part of the extensive storage system which assures New York's millions an unfailing supply of pure water.

MUNICIPAL governments spend millions of dollars annually to protect the water supply of their communities. Reservoirs, aqueducts and filtration plants are maintained at tremendous expense to insure a permanent supply of pure, clear water. But, unless that water reaches the faucets in the same pure state in which it leaves the reservoir, these safeguards are practically destroyed.

That is why it is so important to use Copper or Brass for service pipe. Pipe made of these metals *cannot* rust. Its use eliminates the health menace of rust-contaminated water, the expense of replacements and the damage to pavements that must be torn up when repairs are made.

Although the initial cost is somewhat higher than that of the rustable or so called *rust-resisting* kind, Copper or Brass pipe is an economy in the long run. With them, the first cost is the last. Once installed, they will serve *without attention* for generations.

Before you order service pipe write for our interesting booklet "WATER SERVICES THAT SERVE."

Michigan Valve & Foundry Purchased by Banking Interests

According to recent information, control of the Michigan Valve and Foundry Company of Detroit has been purchased by Chicago and Detroit banking interests. A meeting was held on February 11th, when the new company was organized and officers and directors elected.

Serving on the Board of Directors is Mr. Thomas Neal, who was chairman of the board of General Motors from 1912 to 1915 and who is at present chairman of the board of the Equitable Trust Company of Detroit and a director of the First National Bank of Detroit; Mr. Neil B. Dawes who is a partner in the Chicago banking house of Lane, Roloson and Company; Mr. J. Russell Forgan, a partner in the Chicago banking house of Brokaw and Company; Mr. E. S. Jackson, formerly with the Chrysler organization as auditor; Mr. F. W. Marschner, formerly with the Chalmers Motor Car Company and American Motor Car Company, who has been western manager of the New Departure branch of General Motors Corporation; Mr. R. J. Goldie who has been in the automotive industry for a number of years with Chalmers Motor Car Company, Timken-Detroit Axle Company, and has recently been engaged in consulting engineering work; Mr. W. F. Rockwell, president of the Pittsburgh Equitable Meter Company, the Wisconsin Parts Company, and the American Water Meter Institute, and is a director in the Kensington Water Company, Tri-Cities Water Company, Timken-Detroit Axle Company, Pittsburgh Employers' Association, and chairman of the Distribution Equipment Managers Division of the American Gas Association.

Mr. R. J. Goldie will have active charge of the company's business, serving as vice-president and general manager. The other officers of the company are: Mr. W. F. Rockwell, president and chairman of the board, and Mr. E. S. Jackson, secretary-treasurer.

Established in 1869 as the Galvin Brass and Iron Works, the Michigan Valve and Foundry Company has been well known to the water works industry since its formation. The company was a pioneer in valve and hydrant design and manufacture. It is expected that the new company will adopt a vigorous expansion policy, and announcements of sales offices may be looked for in the near future. It is reported that new machinery is being installed and the capacity of the plant enlarged, and a large amount of business has been booked for immediate delivery where approximately four hundred men are now employed. The company owns some valuable patents and according to announcement will manufacture new lines as well as continue the manufacture of the old lines.

G. H. Jamison, Manager of the Construction Equipment Department of A. H. Cox & Company, Equipment Distributors Located at Seattle, Washington. Cox & Company Represent the Link-Belt Company in Their Territory.

Secretary Davis Speaks at Ground Breaking for Byers Plant

On Feb. 11 formal recognition was taken of the ground breaking for the new $10,000,000 plant which the A. M. Byers Co., of Pittsburgh, Pa., is to construct at Ambridge, Pa. The following excerpts are given from the remarks of Secretary of Labor James Davis as significant of what the Byers New Process might mean to the ferrous industry:

"Heretofore the effort had been to create a machine that would imitate the movements of a human worker. All such efforts failed. Now the metallurgist has stepped in and brought success. He has known better than to try making a machine take the place of a man. Instead of a machine he has invented a process. And where the machine always failed, the process works.

"The part of it which has convinced me of its success is the dropping of the old idea of the 'heat' and substituting a ball of iron weighing 2,500 to 3,000 weight, and making this in a short time.

"There is a saving, too, because under the old method, in the production of 2,500 to 3,000 weight of iron, with two crop ends to the ball, three balls to the heat, and five heats to a day, there were thirty crop ends, but with this new process there are but two crop ends to the same weight. And while, as just stated, it formerly required a day's labor to produce this weight of iron, it can now be produced in half an hour.

"This new process will mean increased production, too; which means giving employment to more men, cheapening the cost of iron so that more of it can be sold and used, and perhaps opening new industries for the working of iron into new products, with still further extension of new jobs to new men.

"In the long run every new process or method or machine that improves or speeds production and cuts down its cost in money and labor, is a boon to humanity."

Southern Plants of Acetylene Products Co. Acquired by Prest-O-Lite Co.

The two acetylene producing plants, formerly owned by the Acetylene Products Co., located at 401 E. Buchanan St., Phoenix, Ariz., and 914 Texas St., El Paso, Tex., have been acquired by the Prest-O-Lite Co., Inc.

These plants are now being operated as units of the Prest-O-Lite chain, which brings the number of plants operated by this company up to 38. These centrally located plants are able to supply the local demand for dissolved acetylene used in welding and cutting.

Mr. Everett R. Kirkland is superintendent of the Phoenix plant, and Mr. Carl F. Chesak is superintendent of the El Paso plant. Mr. R. C. Dagett, whose headquarters are at the San Francisco office, is district superintendent.

Engineers Incorporate

Mr. W. N. Brown of Washington, D. C., who for a number of years has specialized in geodetic and topographic mapping, has announced a firm incorporation to be known as W. N. Brown, Incorporated. Mr. Brown, who is well known as a mining and civil engineer, will have associated with him Mr. A. F. Brooke, Mr. H. V. Jacobs and Mr. W. T. Brown. Offices will be maintained in the Architects Building, 1800 E. Street, N. W. Mr. Brooke and Mr. Jacobs have been associated with Mr. Brown for several years past.

Some of the important accomplishments of Mr. Brown have been: the topographic mapping of the City of Cincinnati, the topographic survey of Naval Reserve No. 1, surveys of large areas along the Mississippi River for flood prevention, and surveys for hydroelectric developments in North Carolina and West Virginia. He is now engaged in revising the topographic survey of the City of Louisville, Ky., covering an area of approximately 40 square miles.

McEverlast Opens Chicago Office

Mr. Lee S. Trainor has been named district manager for the newly opened Chicago office of McEverlast, Inc., Los Angeles, Cal. Mr. Trainor will be located at 35 East Wacker Drive.

A-2437 Valve Box Cover. Tires cannot displace this "Stay-Put" Clow Valve Box Cover.

A-2425 Valve Box — adjustable to any variation in depth of valve. Made in 3 sections of heavy gray iron, thickly tarred.

By ordering valve boxes with pipe often a full car can be made up and the carload rate procured.

even

"Less Carload Lots"

are shipped without delay from the

World's Largest Stock

Clow carries the world's largest and most complete stock of cast iron pipe and fittings. Clow immediately ships orders of any size from this huge stock.

Clow maintains stock at strategic shipping points, cutting down shipping costs on "Less Carload Lots."

Clow always *carries in stock* such special fittings as split sleeves, offsets, half circle pipe, cutting-in-tees, valve boxes, test plugs, Eddy valves and hydrants, and also: bell and spigot, flanged, and threaded pipe, tools, lead and oakum.

You can save precious waiting time—save transportation costs on L. C. L.—with orders to Clow, and speed up installation time with special Clow fittings.

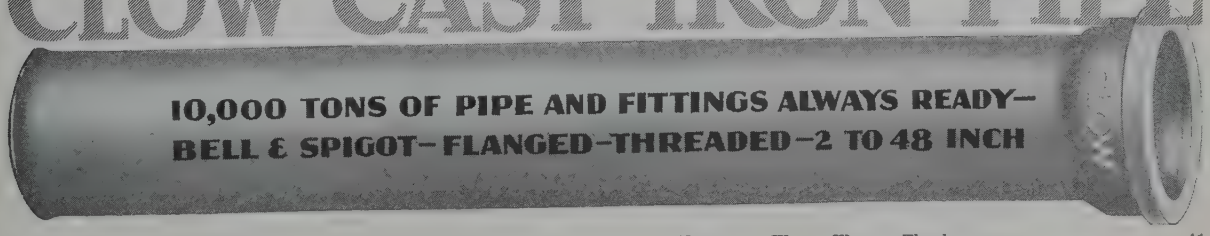
CLOW CAST IRON PIPE



Representatives or New Lines Wanted

Editor's Note.—From time to time we receive letters from distributors wishing to be put in touch with manufacturers of certain lines of equipment, or from manufacturers seeking representatives for their products. Items of this kind will be published and names and addresses furnished interested persons upon request.

New York corporation wishes to establish agencies throughout the country, prefer men specializing in heating and ventilating equipment.

A manufacturer of paving expansion joints is looking for distributors for northern California territory.

New York corporation, producing complete line of coal-tar products, wishes to make dealer connections throughout the country.

Manufacturer of building specialties wishes to establish distributors throughout the country. Manufactures concrete reinforcements and metal lath; Reed clips, form spacers, continuous column tie, continuous chair stirrup, beam bar spacers, slab bar spacers, continuous Hi-chair, continuous anchor slot, sleeping spacing anchor, humpback hairpin clip, lath hanger, stone anchors, straight wire lengths and special wire lengths.

Manufacturer of threadless pipe couplings and tees, with rapidly growing business, is seeking additional representatives.

A contractor's superintendent, located in Florida, would like to represent some road equipment manufacturers in his territory.

A Michigan distributor, with many years' experience, representing at this time prominent manufacturers of pumping machinery, offers the services of an established representative to manufacturers needing increased facilities in this region.

Manufacturers' representatives located in New York would like to add line of heavy contractors' equipment of established reputation, other than the lines now handled by them. They would like exclusive sales rights for such equipment.

New York company would like to represent manufacturers not already established in eastern market, or who would like to make a change in their sales arrangements.

Machinery company in the east is interested in representing established lines of road machinery, with the exception of graders.

A man of many years' experience in the machinery business in the south would like to make a business connection for the sale of road machinery equipment.

Eastern Distributor handling Brick and Clay Products, and similar commodities, would be pleased to get in touch with manufacturers desiring eastern representation.

Machinery distributor established in Porto Rico and Santo Domingo would be pleased to make arrangements to take on new lines in these territories.

Executive with 20 years' experience in selling contractors' and builders' machinery and equipment, is starting new organization and would like to hear from manufacturers desiring representation in Northern California.

Distributor Notes from Barber-Greene

An office has been opened at 527-528 Merchants National Bank Bldg., Cedar Rapids, Ia., by the Barber-Greene Company of Aurora, Ill., manufacturers of ditchers, loaders, conveyors, coal equipment, etc. Mr. Jack Marson of the Barber-Greene Company will have supervision of this office. Mr. Marson has been with the Barber-Greene Company for a number of years.

Another branch office under the supervision of Mr. Marson has been opened at 1106 Nicholas St., Omaha, Neb. Mr. W. E. Toole is in direct charge of this office.

Distributor Notes from Domestic Engine & Pump

Howard E. Read Corporation, 800 N. Delaware Ave., Philadelphia, is to serve that territory as distributor for the complete line of "Domestic Dependable Power Pumps."

The Western Contractors Supply Company, who represent this manufacturer in the Chicago territory, has opened a branch in Indianapolis, Ind., under the managership of Mr. C. F. Messenger. This branch will probably handle the same lines they have been representing in Chicago.

American Hoist & Derrick Appoints Export Sales Manager

The American Hoist & Derrick Company, whose works and main office are at St. Paul, Minn., announces the appointment of Mr. F. E. Bauer, Jr., as export sales manager with offices at 50 Church St., New York City. Mr. Bauer has represented the American Hoist & Derrick Company in foreign fields for many years and has a wide knowledge of business conditions in Asia and the Orient.

C. M. Taylor Becomes Sales Manager for Lincoln Electric

Announcement has been made by the Lincoln Electric Company, Cleveland, O., of the appointment of Mr. C. M. Taylor as sales manager.

Mr. Taylor is a graduate of Western Reserve University and served in the United States Army Air Corps during the war. In 1923 he became factory manager for Lincoln Electric, in whose employ he had been since his college graduation, with the exception of his period of service in the army.

He was elected as vice-president of the company in 1925. The Lincoln Electric are manufacturers of "Stable-Arc" welders and "Linc-Weld" motors.

Bay City Dredge Works Now Bay City Shovels, Inc.

For the purpose of more clearly indicating its present principal type of product (convertible power shovels), the Bay City Dredge Works of Bay City, Mich., announces the corporate name will hereafter be Bay City Shovels, Inc. The announcement from the company states that no change of policy or ownership is contemplated, and the ownership, direction and management of the company will remain in the hands of the individuals who organized and developed the original institution.

Ziegler Company Opens Branch in Fargo

Mr. O. H. Strand, who has been with the Wm. H. Ziegler Company of Minneapolis, Minn., has been placed in charge of a branch office which this company has opened in Fargo, N. D.

Mr. Strand will represent the accounts which the Minneapolis office handles, including a complete line of contractor's equipment, coal handling machines and all kinds of material-handling machines. Among the accounts are Barber-Greene, Bucyrus-Erie, Chain Belt, Sterling Wheelbarrow, Williams Buckets, Plymouth Locomotives, Butler Bins, etc.

Inland Lime & Stone Co. Announces Plans

Inland Lime & Stone Co., a subsidiary of the Inland Steel Co., has announced plans for the development of a large quarry near Manistique, Mich., for the production of chemical and metallurgical lime. It is expected that the quarry will be in production late next year.

The company has also announced plans for the construction of a new harbor near this quarry. Work will commence when navigation opens in the spring.

Road Oil properly applied develops Good Roads at the lowest cost

You can obtain smooth, dustless dirt or gravel roads by properly applying Standard Asphalt Road Oil to the surface.

Standard Road Oil will waterproof the roadway, making a firm, durable surface at all seasons and under all weather conditions. And the cost is low.

Photographs show Wisconsin State Highway No. 35, west of Galesville, being treated with Standard Asphalt Road Oil.

Valuable Information Yours for the Asking

Write Now

Catalog Service

Useful Equipment Information

Watch these trade announcements for new and improved equipment

By writing the manufacturers named and mentioning this magazine, copies of the following catalogs will be sent to you without obligation

TRADE PUBLICATIONS

Portable Compressors.—Bulletin 797, now in its fourth edition, has just been issued by the Chicago Pneumatic Tool Company, 6 East 44th St., New York. The Chicago Pneumatic Portable Compressors, gasoline engine driven are now made in five sizes, viz.: 100, 160, 220, 265 and 310 cu. ft. free air per minute. This equipment is fully described and illustrated in the Bulletin referred to. If writing the manufacturer for a copy, we would appreciate it if you would mention our publication.

Compressors, Drill Sharpeners, Pneumatic Tools.—The Sullivan Machinery Company, 122 South Michigan Avenue, Chicago, Ill., will be pleased to send you a copy of their new eight-page folder, Form 2007, calling special attention to their portable air compressors, mounted to suit your requirements; drills, spaders, hoists and sharpener—all illustrated and described. Catalogs will also be sent upon request, write for information. Kindly mention our magazine, if writing manufacturer,

Paver.—A compact little booklet of 16 pages has just been issued by the Koehring Company, Milwaukee, Wis., on the new 27-E Paver. Each section of this paver is illustrated and described in detail. The new Greater Koehring 27 E is 11 ft. 3 in. high, weighs 22 tons and has great stability because of low center of gravity. Booklet is called The Greater Koehring Paver. Write manufacturer for a copy, mentioning our paper.

Chemicals.—The Hooker Electrochemical Company of 25 Pine St., New York City, or Tacoma, Wash., will be pleased to send you literature concerning the Hooker chemicals. Among the products of this company are listed: Caustic Soda, Liquid Chlorine, Bleaching Powder, Muriatic Acid, Monochlorbenzine, Paradichlorbenzine, Benzoate of Soda, Benzoyl Chloride, Ferric Chloride, etc. Plants are located at Niagara Falls and Tacoma. If writing manufacture, kindly give the name of our paper.

Meter Boxes.—If you will write to H. W. Clark Company, Mattoon, Ill., they will be pleased to send you catalog No. 24, giving full information in regard to their meter protection boxes, constructed of bronze, with locking device and assuring safeguard from climatic conditions. Construction provides for access for repair work or replacements. If requesting copy of catalog, kindly mention our magazine.

Automatic Control Valves.—The Ross Valve Mfg. Co., Inc., Archibald St., Troy, N. Y., will be pleased to furnish you with particulars regarding their automatic pressure control valves for feed water filters, portable fire hydrants, hydraulic engines, hydraulic booster pumps, etc. Write for information, giving the name of our publication.

Sewage Ejectors.—Write for catalog of the Pacific Flush-Tank Co., Ravenswood Ave., Chicago, or 9 Park Place, New York, giving complete information regarding Miller Flush Tank Siphons, sewage pumps and ejectors, portable diaphragm sludge pumps, sewer joint compound, etc.

Cast Iron Pipe.—National Cast Iron Pipe Company, Birmingham, Ala., will be pleased to send you particulars in regard to cast iron pipe for water and gas. Pipe made by sand cast and deLavaud centrifugal processes, also fittings and 2-in. cast iron service pipe. Branches in the principal cities.

Filtration Plants.—The Norwood Engineering Company, Florence, Mass., has much information on the installation of filtration plants which they would be pleased to send you if interested in municipal plants. Write for records of Norwood Municipal Filtration Plants. Kindly mention our magazine.

Reinforced Concrete Pipe.—The Lock Joint Pipe Company, Ampere, N. J., would be pleased to send you full particulars concerning Lock Joint Reinforced Pressure Pipe; its permanence, high carrying capacity, tightness, expansion joints, etc.

Sluice Gates.—Coldwell-Wilcox Company, South Water St., Newburg, N. Y., manufacturers of sluice gates, sheer, flap and butterfly valves, flexible joints, etc., will be pleased to send you full information concerning any of these products. If writing for catalog, kindly mention our paper.

Concrete Pipe.—Write to the Asphalto-Concrete Corporation, 1440 Broadway, New York City, for full information and manufacturing rights for the use of the Moir-Buchanan Centrifugal Process of making concrete pipe. Low manufacturing costs, low laying costs, high density, low absorption and long pipe life are features of this product.

Chlorinator.—The Paradon Manufacturing Company, Arlington, N. J., has issued Bulletin W-22, describing in detail the Paradon Chlorinators for city and private water and sewage systems, industrial plants and swimming pools. If writing for a copy of this bulletin, we would appreciate it if you would mention our magazine.

Rust-Proof Pipe.—"Water Services that Serve" is the title of a booklet issued by the Copper and Brass Research Association, 25 Broadway, New York City. This booklet is a treatise on the need and way of securing a pipe which will withstand soil corrosion on the outside and internal corrosion from the flow of water on the inside. A copy of this booklet will be sent you upon request. If requesting a copy, kindly mention our publication.

Centrifugal Pumps.—The Byron Jackson Pump Co., Berkeley, Calif., with branches in the large cities, will be pleased to send you literature on their sewage pumps, designed for wet or dry pit operation, and which will pass any solid that can enter the pump. The oversize bearings are lubricated from the surface and are protected from pressure fluid by special arrangement of ports. If writing the manufacturer, kindly mention our magazine.

Water Meters.—Write to the Badger Meter Manufacturing Company, Milwaukee, Wis., for detailed bulletin on their complete line of meters, ranging in size from the smallest disc to the 12-in. turbine. This information will point out the way to reduce your pumping costs, by the use of the Badger Turbine Meter at the pumping station and the meters on the service lines. Many changes were made during the past year to increase efficiency and serviceability. If writing for literature, kindly mention our magazine.

Excavator.—Write to the Bucyrus-Erie Company, South Milwaukee, Wis., or Erie, Pa., for bulletin on their D-2 Diesel Drag-Shovel. This shovel is built for the hardest work at a minimum cost. Easily convertible to clamshell-crane, shovel or dragline. Manufacturer will be pleased to furnish you with performance records of this equipment.

Automatic Valve Control.—Cutler-Hammer, Inc., Milwaukee, Wis., has issued their second edition of "Modern Valve Control Practice," describing the C-H automatic valve control system. The new edition contains much additional information and data. There are also new photographs to show the use and installation of motor-driven valves. One of the outstanding features shown in the book is the operation of all valves throughout the plant by means of push-

? What will the years do for you?

? What will **YOU** do with the Years?

Become A Building Estimator

You might doggedly *blast* your way upward in this well paid profession. But the heartbreaking discouragement and years of struggle are unnecessary. To save all this, the Tamblyn System was developed by Gordon C. Tamblyn, who has been building foreman, construction superintendent, estimator, and finally a successful contractor. He learned there is always a shortage of good reliable estimators to protect the contractor's profits. As a result he offers in his System a thoroughly practical training you can follow at your own pace at home. You will gain a thorough knowledge of subjects essential to success at the top of the building industry. As you progress with the course, you progress in a business way. On completion of the work you are fitted for a responsible position as Building Estimator. But you won't stop there—And to start,—now, today, at once—the first step is finding out the details, without the slightest obligation.

This System is an aid, not only to young men determined to make their mark in the building field, but is used by many—

Architects
Superintendents of Construction
Foremen
Engineers and Contractors

A booklet "Your Road Map to Comfort, Security and Prosperity" outlines the upward steps in the building industry, which the Tamblyn System makes clear and easy. Send the coupon for this booklet.

Send us the coupon.

buttons from a single centralized control board. The book also explains in detail the construction and the operating principle of the C-H automatic valve control system, including the new unit for small valves. This is a very comprehensive booklet on the subject and every plant engineer should have a copy, which the manufacturer will be pleased to send upon request. Kindly mention our magazine if asking for copy of bulletin.

Boothal.—This is a water clarifying coagulant, put out by the Booth Chemical Company, Elizabeth, N. J. It is composed of an aluminum salt and the proper proportion of alkali to completely precipitate the alumina. The kind of alkali used is dependent upon requirements. It is particularly well adapted for use in the purification of waters of low alkalinity for public supplies, paper mills, bleacheries, etc. It is shipped in sealed rope paper bags, 60 lb. net, and the package may readily be emptied into the hopper of any suitable dry feed apparatus for application to the water to be coagulated. The feeding is thus more accurate than where solutions are used and less labor is required. The factory of the manufacturer is located at Townley, N. J., but mail is received at Elizabeth, N. J. The manufacturer will be pleased to send you pamphlet giving much information in regard to the use of Boothal, and to point out the economy and simplicity of their system of coagulation. If writing for literature or information, kindly mention our magazine.

Water Purification Equipment.—A booklet has been issued by the International Filter Company, 333 West 25th Place, Chicago, which is a catalog of International Water Purification Equipment and also contains much general information concerning water softening and filtration plants. It is bound in loose leaf style, made up from a series of bulletins, dealing in detail with disc filters; concrete gravity and wood tank type gravity filters; pressure filters; swimming pool filteration; neutralizers; steam purifiers; hot flow water softeners; exchange type (zeolite) water softeners; water purification for ice making, etc. There are several pages devoted to International sales and service, and blank questionnaires to be filled out and mailed in to enable the manufacturer to assist you in solving your problems. The manufacturer will be pleased to send you this complete and comprehensive booklet upon request. Kindly mention our name if asking for copy.

Water Filters.—Information on gravity and pressure plants for all capacities will be furnished you upon request, by the Roberts Filter Mfg. Co., 632 Columbia Ave., Darby, Pa. If writing for information, kindly give the name of our magazine.

Hydraulic Packing.—For water works purposes, on centrifugal or reciprocating pumps and hydraulic valves, write for information concerning Mabbs Rawhide Packing. This packing never becomes hard or glazed. Manufactured by the Mabbs Hydraulic Packing Company, 431 S. Dearborn St., Chicago.

Gas Main Stopper.—The Safety Gas Main Stopper Co., 523 Atlantic Ave., Brooklyn, N. Y., will be pleased to furnish you with particulars on the use of the Goodman Cylindrical Stopper, to stop the flow in sewers. Write for information, giving the name of our publication.

Filter Sands and Gravel.—To meet the most rigid specifiactions on this product write to the Northern Gravel Company, Muscatine, Ia., for information on their "Standard."

Castings.—Write to the South Bend Foundry Company, South Bend, Ind., for information concerning their patented chilled manhole covers. Information furnished on all kinds of gray iron castings.

Valve Housings.—S. E. T. Valve & Hydrant Company, 50 Church St., New York City, will be pleased to send, upon request, descriptive literature on their cast iron sectional valve housings, built in different sizes and depths. This company makes a complete line of municipal street castings and will furnish catalog if desired.

"The Cleaning of Water Mains."—This is the title of a booklet issued by the National Water Main Cleaning Company, 32 Church St., New York, describing the method so successfully used by them for the past twenty years. Write for a copy, giving the name of our magazine.

Hydro-tite.—This is a modern joint material for self-calking joints, for bell and spigot pipe joints, manufactured by the Hydraulic Development Comapny, 50 Church St., New York. Write for particulars.

Service Boxes, Wrenches, Lids, Keys, Etc.—A circular from the H. W. Clark Company, of Mattoon, Ill., manufacturers of water works necessities, describes their Type A, B and M service boxes. They would be pleased to hear from you with specifications and requirements, as their engineers will be glad to help you work out equipment best suited to your needs. Clark wrenches, plugs, service box keys and repair lids are all described in this literature. Ask for folder V-11-3M, and kindly mention our name if writing manufacturer.

"Oxwelding Pressure Vessels" is the title of a booklet just issued by The Linde Air Products Company, 30 East 42nd St., New York City. This is a copyrighted article of the Linde Air Products Company, being a reprint from Oxy-Acetylene Tips of January, 1929. It is an 8-page article dealing with welding problems from the angles of experience, selection of material, design, preparation and technique, inspection and test, and what procedure control has accomplished. This booklet will be sent upon request without charge. If writing the manufacturer for a copy, kindly mention our magazine.

Flood Lights.—"Light Where You Want It" is the title of a little booklet issued by the National Carbide Sales Corporation, 342 Madison Ave., New York City. Construction, sizes, operation, and portability are set forth in this booklet. The National Carbide Lantern, for use of contractors, street repair gangs, tunnel workmen, etc., is described in a folder. This literature, together with prices, will be sent by the manufacturer upon request.

Valves.—Westcott Hub End Valves, manufactured by the Westcott Valve Co., East St. Louis, Ill., are described in a folder issued by the manufacturer. There are but four working parts, the stem, the disc nut and two rocker back discs. Write to manufacturer for full information concerning this product, mentioning our magazine.

Dosing Tank Counter, Sewage Tees, Nozzles, Etc.—Bulletin No. 100, issued by the Pacific Flush-Tank Co., 4241 Ravenswood Ave., Chicago, contains full descriptions, table of weights and price list of this equipment. The new dosing counter for checking the amount of sewage treated by keeping count of the number of times the dosing tanks have discharged may be mounted on the roof of the tank or attached by brackets to the side wall. The counter is protected by a weather-proof cover and has been operated in all kinds of weather. For complete information about the Marley Sewage Tees for sprinkling filter beds and nozzles of the threaded spindle type, lock spindle type and spindle and half spray plug, write to the manufacturer. If requesting literature on this equipment, we would appreciate it if you would mention our magazine. The New York office of this company is at 9 Park Place.

Compressors.—The Sullivan Machinery Company, 122 S. Michigan Ave., Chicago, Ill., has issued a new handbook on Compressed Air Practice, containing numerous suggested uses for compressed air as an aid to speeding production and improving products. It also contains helpful information concerning piping, lubrication and the care of compressed air equipment. The manufacturer will be pleased to send a copy of this book upon request, and we would appreciate it if you would mention our publication if writing.

Industrial Engines.—Bulletin No. 201 has been issued by the Weber Engine Company, Kansas City, Mo. This is a horizontal, 2-cycle, single cylinder, medium compression engine, of comparatively light weight, designed and constructed to insure the greatest strength and rigidity. For users requiring power units of 30-hp., 40-hp., 60-hp., 80-hp., 100-hp. and 125-hp. it affords a thoroughly reliable, compact and economical oil or gas engine of great simplicity. This engine is adaptable for water, sand, drainage or irrigation pumps, electric

"No Permanent Well Water Available," they thought—

—But Sullivan Air Lift Air Made Wells gave Amarillo 7 Million Gallons Daily

Amarillo, Texas, needed more water. An impounded, treated, slack tasting supply would not do. The people wanted well water. And they elected a new mayor on his promise to get it.

Palo Duro Canyon, a nearby tract of land was available. Underlying it was a 25-foot bed of fine quicksand, saturated with water. It lay only 145 feet from the surface.

But wells previously drilled in the canyon had failed. Sand clogged the screens. The wells fell off to less than 90 g.p.m. In some places the sand was pumped out—and the overlying clay caved into the wells.

Nobody thought the sand strata of Palo Duro Canyon could yield a permanent water supply. But a 20-inch "Air Made" Well, pumped by Sullivan Air Lift was installed. It started at 60 g.p.m. In three weeks it was producing 700 g.p.m.

The "Air Made" Well process removed the sand and inserted coarse gravel. Every day the well grew stronger. The city was convinced.

Nine more "Air Made" Wells were installed. Their daily capacity is seven million gallons. And a system of back-blowing repeated at intervals, keeps the wells free from sand—and the water flow ever-increasing.

Sullivan Air Lift has solved many water problems. If your wells slow up—if you are tired of pulling sucker rods and working barrels—if you are having trouble with varying water levels or crooked wells—if you are interested in a water system that has no moving parts in the well to need inspection or repair—investigate modern Sullivan Air Lift. Complete Amarillo story, and Air Lift Booklets are free on request.

Sullivan Machinery Company
130 S. Michigan Ave., Chicago

SULLIVAN TRADE MARK

generators, air compressors, rock crushers, pipe line machinery, mills and industrial plants. The bulletin contains illustrations and cross-sectional drawings and full description. Write for a copy of this bulletin, kindly mentioning our magazine.

Hydrants, Valves, Etc.—Write to the Columbian Iron Works, Chattanooga, Tenn., for descriptive literature of the Columbian Fire hydrants, Gate valves, Valve boxes, Hydrant extension sections, or other water works equipment. We would appreciate it if you would mention our publication if asking for information.

Cast Iron Pipe.—United States Cast Iron Pipe & Foundry Co., Burlington, N. J., will be pleased to send you literature explaining the differences between the deLavaud Cast Iron Pipe and other types of pipe. This is a centrifugally cast pipe in which the graphite particles are finely divided and evenly spread.

Paver.—The Ransome Concrete Machinery Company of Dunellen, N. J., has just issued a very handsome, fully illustrated 36-page book, called "The Master Paver." A complete description is given of the Power Loader, Water Control, Drum, Drum Rollers, Discharge, Boom, Boom Bucket, Supporting Frame, Operating Levers, Engine, Gears, Shafts, Clutches, Main Frame, Crawler, Crawler Drive, Derrick, Distributing Chute and Calcium Chloride Attachment. Important parts are clearly shown in photographs, and pictures of the paver at work on specific jobs are shown, and names of the owners given. The book contains diagrams and specifications of the new Ransome 27-E, and one section is devoted to "Central Mixing Plants." If writing the manufacturer for a copy of this book, kindly give the name of our publication.

Pipe Cutting Tool.—A folder from the Tucker Company, Inc., 75 Murray Street, New York City, gives a detailed description and price list of parts in all sizes of their cutter for cast iron pipe. This tool can be used in any ordinary trench without extra excavating. It will cut a piece one inch long or more at any point without starting joints or otherwise disturbing the main, and will make a clean cut in a gas or water main in the trench. Write to the Tucker Company for literature and price list of the Anderson Pipe Cutting Tool. In writing, kindly give the name of our magazine.

Cast Iron Pipe.—James B. Clow & Sons, 201-299 North Talman Avenue, Chicago, with foundries at Coshocton, Ohio, Newcomerstown, Ohio, and Birmingham, Alabama, carry large stock of pipe at points where large supplies can be obtained on short notice. Wire or write them concerning your requirements, they will be glad to care for your needs without delay. Mention our magazine when writing this company.

Cast Iron Pipe.—The Central Foundry Company, manufacturers of cast iron pipe with offices located in the principal cities, will be pleased to have you call at the nearest office or write to the New York office, 420 Lexington Avenue, for complete information in regard to their product, an iron to iron joined pipe, allowing for expansion and contraction, vibration and uneven ground settlement. Used for water supply, fire protection and other service.

Hydrants and Valves.—The Mathews Fire Hydrants, built for easy installation and so that an extension section may be used to adapt them to new grades, are described in literature of the R. D. Wood & Co., Philadelphia. If you will write to Mr. C. Becker of this company he will gladly send you full information about their sand-cast and "sand-spun" centrifugal cast iron pipe fittings, valves, boxes and hydrants. Please use the name of our magazine if writing.

Manhole and Catch Basin Covers.—Write to Wm. E. Dee Company, 30 North La Salle, Chicago, Ill., for particulars concerning the different types of manhole and catch basin covers. Prices will be included on request. If writing, kindly use the name of our magazine.

Chlorination.—Wallace & Tiernan, Newark, New Jersey, manufacturers of chlorine control apparatus will be pleased to send you full particulars in regard to the sterilization of water by their method, and to furnish you with record of cities where their apparatus is being used. If writing for information, we would like to have you mention our magazine.

Valves.—Golden-Anderson Valve Specialty Company located in the Fulton Building, Pittsburgh, have issued a descriptive and data catalog on their automatic valves for steam and water service. Full details are given on each page as to construction, operation variations together with cross-section drawings. Data required for ordering is made very clear. If you desire a copy of this catalog write to Mr. J. A. Voland of the Golden-Anderson Company mentioning the name of our magazine.

Francois Cementation Process.—The Dravo Contracting Co. have acquired the sole American rights to the Francois patents, and have a highly skilled staff who will be pleased to help you with your problems. This method of grouting covers chemical processes for a hundred and one different cases, the engineers of the Dravo Company are ready to help you solve your problems. Write to their company at Pittsburgh, Pa., mentioning our magazine.

Hydrants, Valves, etc.—Full particulars for supplies needed by water works and fire departments will be sent upon request by the Bourbon Copper & Brass Works Co., 618 E. Front St., Cincinnati, Ohio, manufacturers of fire hydrants, gate valves, and extension valve boxes. Write for their catalog, giving the name of our magazine.

Sewer Cleaning Machine.—W. H. Stewart, whose factory is at Walkerville, Ontario, has branches in St. Louis, Mo., Jacksonville, Fla., and Boston, Mass., so that his patrons on this side of the border may be served without paying duty. Literature describing his sewer and conduit rods will be furnished on request. Rods will be shipped on trial. If writing to Mr. Stewart for information concerning his equipment kindly mention our publication.

Zeolite.—"Softening Municipal Water Supplies by the Use of Zeolite" is the title of a bulletin issued by the Zeolite Chemical Company, 140 Cedar Street, New York City. This booklet describes Green Sand, a natural base exchange Zeolite Mineral, used for the purpose stated. Write to Mr. R. E. Wagner of the Zeolite Company for a copy of this bulletin. If writing, we would appreciate it if you would mention this magazine.

Western Hot Patch Plant.—A product of the Austin-Western Road Machinery Company, 400 North Michigan Avenue, Chicago, for keeping roads in repair winter and summer. Write to their Chicago office or any branch office for their Bulletin on Winter Repair Work for particulars concerning this equipment. We would appreciate it if you would mention our magazine.

Cast Iron Pipe.—The McWane Cast Iron Pipe Company of Birmingham, Alabama, will be pleased to send upon request, illustrated literature giving full information concerning their product, its cost, life and uses. The western branch of this organization is the Pacific States Cast Iron Pipe Company of Provo, Utah.

Aerator.—The Simplex Surface Aerator, an effective means of producing "activated Sludge," is fully described in Bulletin E-5-28, issued by the Simplex Ejector and Aerator Corporation. The Chicago address is 2528 W. Madison St., Chicago. If writing for literature, kindly mention our magazine.

Automatic Air-Lift. — The Sullivan Machinery Company, 130 South Michigan Avenue, Chicago, has a handbook on their automatic air lift, and special automatic control information of particular interest to water works superintendents. Their catalogs also describe air made wells, and contain a complete story of how a city elected a mayor on his promise to get them well water, and how his promise was kept by the use of this method. Kindly mention our publication when requesting catalogs.

Wrought Iron Pipe.—"The Installation Cost of Pipe" is the title of a Bulletin issued by the A. M. Byers Company, Pittsburgh, Pa., containing cost data and full particulars concerning

No Floats or Fixtures but Absolute Water Control

A constant water level can be automatically maintained in reservoirs, tanks and standpipes by the use of

GOLDEN-ANDERSON

Automatic Cushioned Controlling Altitude Valves

These valves are always cushioned in closing and opening. They are extensively used for automatically maintaining a uniform stage of water in reservoirs, tanks and standpipes. No valves inside. No floats or fixtures, inside or outside of tanks. No freezing troubles.

Three ways of closing these valves:

1st—Automatically, by Water.
2nd—By Electricity, if desired.
3rd—By Hand.

May also be arranged to automatically close when a break occurs in the mains. When necessary they may be so connected as to "work both ways" on a single line of pipe.

GOLDEN-ANDERSON

Pat. Automatic Cushioned Water Pressure Regulating Valves

1. Maintain a constant reduced pressure regardless of fluctuations on high pressure side.
2. Perfectly Cushioned by water and air. No metal-to-metal seats.
3. The best valve made for maintaining a constant low pressure where consumption is continuous.
4. Operates quickly or slowly as required—No attention necessary.
5. Positively no hammering or sticking. Sizes to 24 in.

GOLDEN-ANDERSON

Pat. Cushioned Water Relief Valves

1. Automatically relieve excess pressure.
2. Prevent stress strain and bursting of mains.
3. Correct mechanical construction.
4. Perfect air and water cushioning.
5. No metal - to - metal seats. No hammering or shocks.
6. Angle and globe pattern. Sizes 3 to 24-in.

GOLDEN-ANDERSON

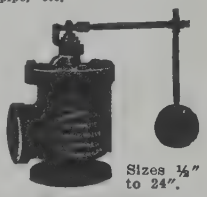
Pat. Automatic Cushioned Controlling Float Valves

1. Automatically maintain uniform level in heaters, tanks, etc.
2. Air and water cushioned.
3. No metal - to - metal seats.
4. No waste of water.
5. No water hammer or shock.
6. Angle or Globe, patterns to 24-in.

GOLDEN-ANDERSON

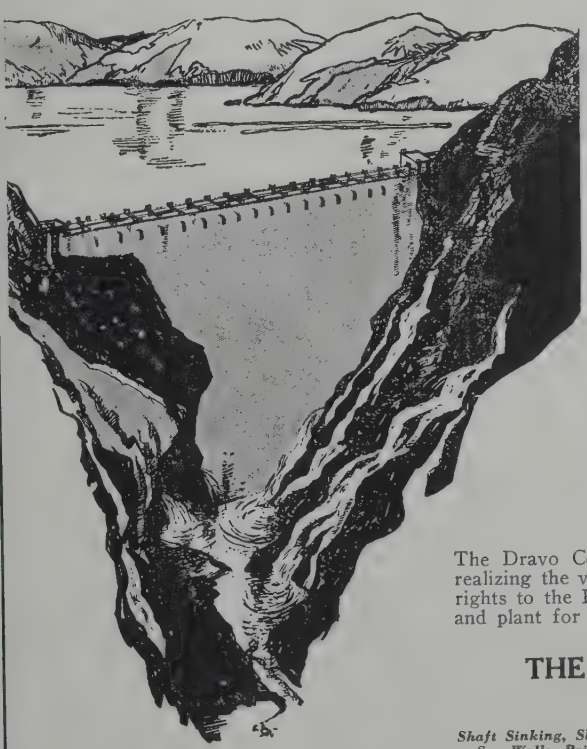
Pat. Automatic Cushioned Water Float Valves

1. Automatically Maintain Uniform Water Levels in Tanks, Standpipe, etc.
2. Instantly Adjusted to Operate Quickly or Slowly.
3. Floats Swivel to any Angle—Most Satisfactory Float Valves known.
4. No Metal - to-Metal Seats—No Water Hammer or Shock.
5. Cushioned by Air and Water.



Sizes ½" to 24".

Golden-Anderson Valve Specialty Co., 1385 Fulton Bldg., Pittsburgh, Pa.



Have You a Leakage Problem?

Francois Cementation Process

The surest and most economical method of overcoming difficulties due to the presence of water or bad ground.

The cementation process—the specialized high pressure injection of liquid cement mixtures into cavities, fissures, or cracks—has been developed to a high degree in Europe, and more particularly in Great Britain by the Francois Cementation Company, who have a long list of successful contracts to their credit, including internationally known structures.

Some features of the Francois Process are:

Grout is under perfect control;
Pressures to 3,000 pounds per square inch if required;
Chemical processes for a hundred and one different cases;
Wide experience in many years specialization.

The Dravo Contracting Company, after many years successful work and realizing the value of specialized grouting, have acquired the sole American rights to the Francois patents, and at their disposal is a highly skilled staff and plant for the execution of contracts.

THE DRAVO CONTRACTING COMPANY
PITTSBURGH, PA.

Shaft Sinking, Slopes, Tunnels, Pneumatic Caissons, Submarine Construction, Locks, Dams, Sea Walls, Bridge Piers, Steel Barges, Steel Towboats, Inland Waterway, Floating and Terminal Equipment, Steel Headframes, Steel and Concrete Tipples.

this product and its uses. Ask for Bulletin No. 38, giving the name of our magazine.

Trimo.—The trade name by which the wrenches manufactured by the Trimont Manufacturing Company, Inc., are known. These pipe wrenches are made with a braced frame to stand the hardest strain, with hard biting jaws that can be easily renewed, and the heat treated steel handles assure tremendous strength. Write for detailed information and prices to Roxbury (Boston), Mass., mentioning the name of this magazine.

Gate Valves.—The Darling Valve & Mfg. Company, with offices in New York, Chicago, Houston and Oklahoma City and headquarters in Williamsport, Pa., will be pleased to send you literature on the construction and operation of the Darling Gate Valves. If writing for particulars on this product, kindly mention our paper.

Deep Well Works.—The United Iron Works, Inc., of Springfield, Mo., with general offices in Kansas City, manufacturers of "Pomona" double stroke deep well power pumps, offer without obligation methods for economically solving pumping problems. The engineering experts will be pleased to advise with you. Descriptive catalogs will be sent upon request. If writing, kindly give the name of our magazine.

Pumps. — New Catalog containing complete information on centrifugal pumps, plunger pumps, and deep well power heads may now be obtained by writing the American Well Works, Aurora, Illinois. Their engineering department will be pleased to discuss your needs with you, recommending the best equipment for your purposes. Kindly use the name of our publication if writing for information.

Disposal Plants. — Fairbanks-Morse and Co., Chicago, or any of their branch offices in the principal cities will be pleased to furnish complete details concerning their F-M Trash pumps for handling unscreened sewage direct from sewers. Write for information, giving the name of our publication.

Cast Iron Pipe.—"The Two-Main System" is the title of a book which The Cast Iron Pipe Research Association is distributing free to city officials, engineers and taxpayers. It is a pocket size volume, written in non-technical style, with charts, drawings and photographs to make the telling more forceful. It explains how the two-main system is able to meet the demand of the taxpayer for a means of preventing the tearing up of costly streets for extensions, repairs, etc. A valuable book for public officials and engineers. Write to Mr. Thos. F. Wolfe, Research Engineer, Peoples Gas Bldg., The Cast Iron Pipe Research Association, Chicago, for a copy, kindly mentioning the name of our paper.

Clay Pipe.—The Clay Products Association, Conway Building, Chicago, makers of vitrified clay pipe, will be pleased to send you full information regarding this product.

Meters — Gauges — Valves. — Information on complete equipment for filtration plants may be secured by writing the Simplex Valve & Meter Company, 6749 Upland Street, Philadelphia, Pa. The Simplex Rate of Flow Controller is adaptable to large and small filter plants from 30-inch effuent to 3-inch. The Simplex Venture Type Meter indicates, records and totalizes the rate of flow, and the Simplex Filter Gauges may be had in many combinations of Indicating, Recording and Totalizing. If writing for particulars on this equipment, kindly mention our magazine.

Filtration Plants.—Norwood Engineering Company, Florence, Mass., will be pleased to send you full particulars regarding the Norwood Municipal Filtration Plants. Kindly give the name of our publication if requesting information.

Pipe Cutter.—Manufactured in two sizes for all types of pipe by the Ellis & Ford Mfg. Co., 18 Piquette Ave., Detroit, Mich. Circular giving full particulars will be sent by manufacturer upon request. We would appreciate it if you would mention our magazine, if writing.

Meter Boxes.—The Ford Meter Box Company of Wabash, Indiana, have a special bulletin on the Ford Type S Meter Boxes for "warmer climates." Meters can be set or removed in an instant. The Ford standard testers can be adapted for testing meters in a series, each meter clamped in separately and the work economically and conveniently handled.

Centrifugal Pumps. — Catalog-W-67 issued by DeLaval Steam Turbine Co., Trenton, N. J., gives methods of meeting water supply problems at the lowest cost. Full information regarding geared steam turbine driven pumps, electric motor driven pumps or internal combustion engine driven pumps. If writing for a copy of this booklet, kindly give the name of our publication.

Centrifugal Pumps.—In order to be of assistance to users in choosing the right pump for their needs, Bulletin 1632-I has been issued by the Allis-Chalmers, Milwaukee, Wis. Types for steam turbine drive, motor drive or gasoline engine drive are described to best fit the purposes of installation. Write to Mr. H. G. Hoffman for copy of this bulletin.

Standard Construction Castings.—This is the title of a catalog which is attractive and different from the usual. It has just been issued by the Flockhart Foundry Company, 80 Polk Street, Newark, N. J. The booklet contains a Foreword explaining that the catalog is the result of a study, covering the past eight years, of the designs of castings used by governmental bodies, public utlities, etc., with a view to classifying and simplifying existing types, developing new types in some cases, but always seeking permanence and reasonable cost. The company was aided in this work by prominent engineers and State Highway Commissions, to whom they give credit. The table of contents itemizes twenty-three data sheets, each covering a separate type of casting. The data sheets then follow, each with sectional drawings, descriptions, with dimensions and code numbers for ordering. The Flockhart Company has had forty-eight years of experience in making castings for the construction field, and offers a free engineering service to their patrons in solving their problems. In addition to the products listed in the catalog, the company presents a list of products about which they will be pleased to send you detailed information. If writing for Standard Construction Castings ask for Catalog No. 101, which will be sent you without obligation. We would appreciate it if you would mention our magazine if writing manufacturer.

Chemicals.—A very complete and handsome book has just been issued by the LaMotte Chemical Products Company, McCormick Building, Baltimore, Md., called "The A B C of Hydrogen Ion Control." This is the fifth edition of this book, bearing the 1929 copyright of the company. It deals with the Colorimetric Method of determining hydrogen ion concentration and for water analysis, and serves as a text-book and guide to those just taking up the subject. It is written in terms readily understood by the non-technical reader. It also contains a complete line of materials and equipment for the analysis of water, sewage and industrial wastes. From the introduction through to the very end this will be found interesting and instructive reading. A Research Department is maintained by the company and it is always at the service of their patrons. A copy of "The A B C" will be sent you upon request, and we would appreciate it if you would mention our magazine if writing the manufacturer.

Tarvia.—A product for road construction, repair and maintenance manufactured by The Barrett Company, with offices in all the principal cities of the United States and Canada. Write to any of the branches of this company for help in solving your road problems.

SAVE YOUR TIME! USE OUR SERVICE! Prices on equipment, names of manufacturers or their catalogs will be cheerfully furnished to you by our Service Department. Write Municipal News and Water Works, 221 E. 20th St., Chicago.

ADVANTAGES OF PERMANENT PLANT FOR CONCRETE PIPE MANUFACTURE

No. 5 of Technical Series

Atlantic Cement Products, Inc.
Hicksville, Long Island, N. Y.

Improvement in quality will lead to increased use of concrete pipe

No loss of time because of bad weather will result in lower manufacturing costs with steady employment of labor and equipment. Accurate forecasts of production can be made. Being protected, equipment lasts longer. When under shelter and provided with comfortable and familiar conditions, workmen produce more. The smaller turn-over in labor favorably affects production.

With activities concentrated, closer supervision results. The superintendent can watch every step in the process of manufacture and prevent mistakes.

The Purchaser and his Engineer should satisfy themselves that the Pipe Manufacturer has modern equipment; employs modern methods; has proper facilities for making tests; and that an Inspector will easily be able to see what he should. The Manufacturer who has a modern permanent plant with easy access for inspection of process and product is naturally favored by Engineer and Purchaser.

The permanent concrete pipe plant produces a uniform product. It can run summer and winter—day and night if need be—and the product will not suffer in quality. The stock can be built up prior to heavy spring demand.

Discriminating Purchasers are paying more for centrifugally made concrete pipe. A fair investigation will prove the superiority of the

MOIR-BUCHANAN Centrifugal Process

DISTRIBUTOR NEWS

The Distributor's Department in the Gillette Construction Group

SOS

This department is conducted by Station GCG (The Gillette Construction Group), but we need your help and cooperation. The more stories and items you send in to us, the more interesting will this section of our papers be to all our readers. Let us hear from you. Address The Editor, Distributor News, Gillette Publishing Company, 221 East 20th Street, Chicago.

Distributor Advertising Service Announced by Petroleum Heat and Power Company

An intensive advertising campaign has been planned by the Petroleum Heat & Power Co. of Stamford, Conn., to include newspapers, general and trade magazines, direct mail campaign, billboard and other features, which they expect to tie up directly with their distributors and dealers by means of a publicity service bureau.

The organization of this advertising and publicity service bureau for the benefit of the distributor is in the hands of Mr. J. R. Lunstead, formerly associated with the Radio Corporation of America. This direct tieup of the dealers' local advertising with national advertisements is an indication of the importance of the distributor in the sales promotional work.

There will be available for distributors and dealers, seasonal tie-up in newspaper ads for which either electros or complete matrices will be furnished, reprints of national advertisements, etc. This material will be distributed by the new service bureau, and the distributors will be informed on the latest methods of preparing and placing their local advertising, and in securing the best results from their efforts. The dealer is offered the personel service of the publicity bureau staff.

Feenaughty Machinery Represents Galion in Oregon, Washington and Idaho

Feenaughty Machinery Company, which was appointed several months ago as distributors in Oregon for the Galion Iron Works & Manufacturing Company, has now been given the Washington and Idaho territory as well. This announcement was made by the Pacific Coast representative of the Galion Company, Mr. Y. T. Leftwich. This change was made when the Jeffrey Manufacturing Company acquired control of the common stock of the Galion concern.

Butler Bin Make Several New Appointments

Fourteen new distributors have been appointed to handle the products of the Butler Bin Company of Waukesha, Wis., manufacturers of steel storage bins, weighing and measuring hoppers, bin gates, etc. The new representatives are: Arizona Road Machinery Co., Phoenix, Ariz.; General Equipment Mach. Co., Miami, Fla.; Hofius-Ferris Equip. Co., Spokane, Wash.; J. B. Harbison Equip. Co., Little Rock, Ark.; Loggers & Contractors Equip. Co., Portland, Ore.; Mechanical Supplies Co., Cincinnati, O.; W. T. McDonald & Co., Indianapolis, Ind.; New Mexico Road Machinery Co., Albuquerque, N. M.; Stannard-Arnold Co., Salt Lake City,

Suddenly, out of a spring sky . . .

An Advertisement of the
American Telephone and Telegraph Company

All was well on the telephone front on April 27, 1928. Suddenly, out of a spring sky, rain began to fall over central Pennsylvania. As night came on this turned into a furious storm of sleet, snow and wind. Inside of 48 hours, 3700 telephone poles were down. Seven thousand miles of wire tangled wreckage. Thirty-nine exchanges isolated. Eleven thousand telephones silent.

Repair crews were instantly mobilized and sent to the scene. From Philadelphia 47 crews came. Other parts of Pennsylvania sent 13. New Jersey, 6. New York, 4. Ohio, 6. Maryland and West Virginia, 12. In record time, 1000 men were stringing insulated wire and temporary cables along the highways, on fences and on the ground.

Within 72 hours the isolated exchanges were connected and the 11,000 telephones back in service. Then, while the temporary construction carried on, neighboring Bell System warehouses poured out all needed equipment, new poles were set, new crossarms placed and new wire and cable run.

In any crisis there are no state lines in the Bell System. In all emergencies of flood or storm, as well as in the daily tasks of extending and maintaining the nation-wide network, is seen the wisdom of One Policy, One System, Universal Service. Better and better telephone service at the lowest cost is the goal of the Bell System. Present improvements constantly going into effect are but the foundation for the greater service of the future.

Link-Belt Elects Watson Vice-President

James S. Watson, a Philadelphia youth thirty-four years ago, entered the local plant of the Link-Belt Company. Announcement has just been made of his election to the vice-presidency of the company. His headquarters will be at the Dodge works in Indianapolis.

After Mr. Watson had been with the company about eight years, gaining experience in various departments, he was chosen to take charge of the exploita-

James S. Watson

tion of Link-Belt silent chain as a power transmitting medium. This was in January, 1903, when silent chain was new, having been introduced in 1900. Since then Mr. Watson has become well known throughout the country as the head of the drive chain division of his company.

For the past nine years he has been located at the company's Dodge Works in Indianapolis, where as general manager, he has been in charge of production and sales of Link-Belt silent and roller chain drives, as well as Herringbone speed reducers through a band of power transmission engineers located in all the principal cities.

With this item we present a picture of the outward and visible Mr. Watson, but for knowledge of the man himself, we quote his business ideals:

"A definite knowledge of one's product; faith in one's self; belief in one's business associates; respect for one's competitors; and a general adherence to the Golden Rule."

Portland Cement Association Appoints New Southwestern Manager

Mr. Charles A. Clark, formerly district engineer in Dallas, Texas, for the Portland Cement Association, has been appointed manager of the Southwestern offices of the company, with headquarters at Kansas City, according to announcement of Mr. William M. Kinney, general manager of the association.

Mr. Clark is an alumnus of the University of Missouri, and during the past twenty years has been associated with several important engineering projects. On the Florida East Coast Railway from mainland to Key West, he acted as concrete inspector, and later was active in the development of Illinois' model highway system.

In 1917, Mr. Clark joined the staff of the Portland Cement Association as a fieldman for Missouri and Oklahoma. After a period of administrative work in the Chicago general office, he was assigned to Dallas as district engineer. From his Kansas City office, he will have supervision over Texas, Oklahoma, Kansas, Nebraska and Western Missouri. Mr. Clark is to succeed Mr. Forest Kaufman, resigned.

Many New Distributors to Handle REX Equipment

The Chain Belt Company has just appointed fourteen new distributors in almost as many states, to handle their line of REX equipment, including mixers, pavers, pumps, saw rigs, plaster and mortar mixers. The recent appointments are: The G. C. Phillips Tractor Co., Birmingham, Ala.; McGowin-Lyons Hardware & Supply Co.; Mobile, Ala.; Burnite Machinery Company, Denver, Colo.; Fuchs Equipment Company, Omaha, Neb.; Gierke-Robinson Co., Davenport, Ia.; Sheehan & Company, El Paso, Tex.; The Arizona Road Machinery Co. (branch of Sheehan), Phoenix, Ariz.; The New Mexico Road Machinery Co. (branch of Sheehan), Albuquerque, N. M.; Youngstown Mill Supply Company, Youngstown, O.; The LaLance Equipment Co., Huntington, W. Va.; McNeilly Machinery Company, Columbus, O.; Earnest Brothers, Norfolk, Va.; The Clyde Company, New Orleans, La.; Stannard-Arnold Machinery Co., Salt Lake City, Utah.

Huebotter Joins Waukesha Engineering Staff

Mr. H. A. Huebotter, well known to automotive and Diesel engineers, has recently joined the technical staff of the Waukesha Motor Company, Waukesha, Wis. He comes to the Waukesha Motor Company from the Butler Manufacturing Company, Indianapolis, Ind., where he was chief engineer.

Mr. Huebotter has been engaged in both practical and theoretical research for a number of years. From the time of his graduation from Purdue University in 1912, he has devoted his energies to automotive research, design and production. Extensive opportunities for research were available to Mr. Huebotter, when for several years at Purdue, he conducted classroom instruction, and worked out various experimental problems.

He is a member of the Society of Automotive Engineers, and is the author of the book "Mechanics of the Gasoline Engine."

M. B. Rider Joins H. O. Penn Mach. Company

Mr. M. B. Rider, formerly New York sales manager for the T. L. Smith Company, has joined the H. O. Penn Machinery Company as sales manager of the road building equipment division. Mr. Rider is well known in the east because of his long experience with road building equipment and the construction industry in general.

The H. O. Penn Machinery Company represent a number of prominent manufacturers of construction equipment, and Mr. Rider will handle the sales of all road construction equipment. Among the manufacturers whose products he will sell are Chain Belt Company and Butler Bin Company.

Atlanta Branch Opened by J. D. Adams Company

A new branch office and warehouse has been opened in Atlanta by J. D. Adams Company to serve their Georgia trade.

For a number of years the Adams adjustable leaning wheel graders and other road equipment have been sold by distributors in Georgia. This equipment is now being sold and serviced by the Atlanta branch.

Business Outlook in Maryland Good

J. J. Smith, 3620 Ednor Road, Baltimore, recently appointed representative for the Chicago Pump Company, reports that the outlook for business in Maryland and the District of Columbia for lines handled by him is unusually good.

In addition to a complete line of electrically-driven pumping machinery, Mr. Smith handles cast iron boilers, steel boilers of high and low pressure, ventilating equipment and hot water storage heaters.

Recent Appointments

The Chicago Pump Company have recently added to their list of representatives the following: Mr. Bernhard E. Hovind, 326 Jay St., La Crosse, Wis., and S. T. Weaver Company, 1002 N. Clinch St., Knoxville, Tenn.

Not in the bag

ANDREW J. PIPE emphatically denies the rumor that his recent disastrous contest with a Trimo pipe wrench was "in the bag."

"I know that I made a miserable showing, but I want all pipe lovers to know that I did my best.

"This new Trimo has a vicious grip and an ugly disposition. In fact it makes me feel a little shaky just to think about it."

The day when a stubborn pipe or nut could put up a winning fight is gone now. Trimo, Improved and Mightier, makes 'em all say "uncle."

Look over the rugged frame, heat treated handle, business-like jaws—what chance has a pipe got with this *all steel wrench?*

SERVICE EXCHANGE
For
Manufacturers or Distributors

Editor's Note.—From time to time we receive letters from distributors wishing to be put in touch with manufacturers of certain lines of equipment, or from manufacturers seeking representatives for their products. Items of this kind will be published and names and addresses furnished interested persons upon request.

New Lines Wanted

Road machinery distributor would like to secure exclusive sales rights for state of Mississippi for line of automatic or self-loading wheeled scraper.

A Michigan distributor, with many years' experience, representing at this time prominent manufacturers of pumping machinery, offers the services of an established representative to manufacturers needing increased facilities in this region.

Manufacturers' representatives located in New York would like to add line of heavy contractors' equipment of established reputation, other than the lines now handled by them. They would like exclusive sales rights for such equipment.

New York company would like to represent manufacturers not already established in eastern market, or who would like to make a change in their sales arrangements.

Machinery company in the east is interested in representing established lines of road machinery, with the exception of graders.

A man of many years' experience in the machinery business in the south would like to make a business connection for the sale of road machinery equipment.

Eastern Distributor handling Brick and Clay Products, and similar commodities, would be pleased to get in touch with manufacturers desiring eastern representation.

Machinery distributor established in Porto Rico and Santo Domingo would be pleased to make arrangements to take on new lines in these territories.

Executive with 20 years' experience in selling contractors' and builders' machinery and equipment, is starting new organization and would like to hear from manufacturers desiring representation in Northern California.

A contractor's superintendent, located in Florida, would like to represent some road equipment manufacturers in his territory.

District respresentative for sanitary engineering specialties would be interested in any line in the water works field. Has had experience in field of filters, softeners and water meters.

Representatives Wanted

Manufacturer of hoisting machinery and air compressors has open territory in New York and New England states for aggressive distributor.

Manufacturer of two cycle oil and gas engines in sizes from 30 to 125 H. P. adaptable for water works and many industrial purposes, wishes to establish points of distribution throughout the country.

New York corporation wishes to establish agencies throughout the country, prefer men specializing in heating and ventilating equipment.

A manufacturer of paving expansion joints is looking for distributors for northern California territory.

New York corporation, producing complete line of coal-tar products, wishes to make dealer connections throughout the country.

Manufacturer of building specialties wishes to establish distributors throughout the country. Manufactures concrete reinforcements and metal lath; Reed clips, form spacers, continuous column tie, continuous chair stirrup, beam bar spacers, slab bar spacers, continuous Hi-chair, continuous anchor slot, sleeping spacing anchor, humpback hairpin clip, lath hanger, stone anchors, straight wire lengths and special wire lengths.

Manufacturer of threadless pipe couplings and tees, with rapidly growing business, is seeking additional representatives.

Manufacturer of metal tie and spacer wishes to establish distributing points throughout the country.

Manufacturer has some attractive territory available for distributors for complete line of generators, and centrifugal, diaphragm and piston pumps.

Charles Edison Heads Splitdorf Companies

Charles Edison, son of the famous inventor, Thomas A. Edison, and one of the younger outstanding figures in the industrial life of the country, is the new president of the Splitdorf-Bethlehem Electrical Company and the Splitdorf Electrical Company.

The Splitdorf Electrical Company, well known as manufacturers of magnetos, spark plugs and other ignition devices, has for several months been making parts for the Edison Radio. The assembling of chassis for the Edison Radio has now been concentrated in the Splitdorf Radio Corporation, of

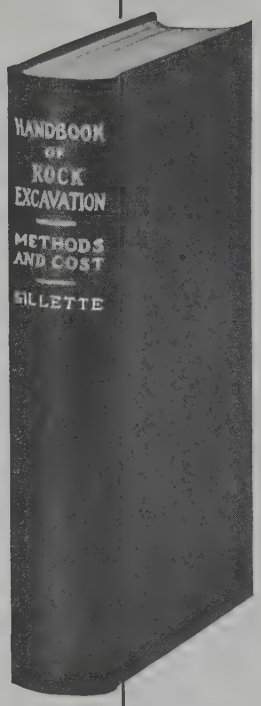
Charles Edison

which Mr. Edison is also the president, thus leaving the Splitdorf Electrical Company free to continue in its research and development in the ignition field.

Associated with Mr. Edison in the management of the Splitdorf Companies are executives who have had long, wide and varied experience in the Edison industries. Among them are: L. W. McChesney, vice-president and general manager; R. H. Allen, vice-president in charge of finance; H. F. Miller, treasurer; Howard H. Eckert, secretary, and Henry Lanahan, general counsel. Other announcements as a result of the reorganization of the affairs of the companies are L. S. Dunham, chief engineer; H. E. Krause, works engineer, both located at Newark, N. J.; and W. L. Kaiser as central district manager, with headquarters at Chicago.

J. L. Hart Machinery Company formerly known as the Coulter-Hart Equipment Company of Tampa, Fla. will represent George Haiss Mfg. Co., Inc., of New York, in the northern and eastern part of Florida.

WHO PAYS for Over-Breakage ?



Ever find yourself losing on the removal of rock slips or falls not included within the definite "neat lines" specified and shown in the blue prints? H. P. Gillette's "Handbook of Rock Excavation" (on page 15) points out this pitfall in which many a contractor has dropped a good share of his profits. You are told how to guard against it.

This is only one helpful point of the thousands contained in the Handbook. Much more valuable are those that go beyond the prevention of loss and show new ways to increase profits. All in all, there is a wealth of useful information that belongs at the elbow of the man who has a rock job on hand or ahead of him.

Our offer gives you the opportunity to examine every detail of this standard book for ten days. Read the coupon, fill in and mail.

Akers of McWane Co. Joins Cox Agency

Mr. Arthur K. Akers of Birmingham, Ala., is rapidly becoming known as a writer of fiction, but as a writer of autobiography we were able to secure but little from him. Mr. Akers has so many friends in the water works field we take pleasure in presenting his picture and in giving the reason for his recent change in business connections.

As publicity manager for the McWane Cast Iron Pipe Company, Arthur K. Akers entered the advertising field in 1922. This business grew rapidly until in 1929 it ranks with the larger producers of cast iron pipe in America.

Arthur K. Akers

It has new foundries in Birmingham and Provo, Utah, the latter operating as the Pacific States Cast Iron Pipe Company, and serving the eleven western states. The McWane companies have always been liberal users of trade journal space.

In 1925 Mr. Akers began contributing short stories to the magazines, principally to RED BOOK. His stories of negro life in Alabama have since become one of the features of that magazine, one of them appearing practically every month over the past two years.

Other magazines have since begun requesting material from him to the point where the double load of full-time advertising work and a heavy fiction output has become such a burden that Mr. Akers has been forced to make a change in his arrangements.

Under the new plan, he will devote himself more largely to fiction writing, but has associated himself with the Cox Advertising Agency, of Birmingham, where he will continue to create and place the McWane Cast Iron Pipe Company and Pacific States Cast Iron Pipe Company publicity, as well as have oversight of that agency's other new industrial accounts.

Mr. Akers expresses the hope that he may continue his attendance at the water works and gas association annual conventions where he has been a familiar figure in connection with the exhibits of the McWane companies for the past seven years.

We are very happy that Mr. Akers' services are still to be available in the field of industrial advertising, and feel sure that the circulation of RED BOOK will show a marked increase in readers from the water works field.

Chain Belt Appoints New Advertising Manager Trade Publications

Mr. R. A. Shilbauer, who joined the Chain Belt Company of Milwaukee in 1920 as a rate-setter (and worked in that capacity in the various departments of the company's Grey Iron Foundry and Chain assembly plants on Park street and later became assistant advertising manager, has now been made advertising manager. He has been connected with the advertising department since 1925.

The Chain Belt Company manufactures engineering and conveying equipment, chain, transmission, concrete mixers and pavers, which are recognized under the trade name "Rex." The company also operates a plant in Cleveland, Ohio, under the name of the Stearns Conveyor Company, where belt conveyors and bulk material storage systems are made. The Chain Belt Company is a part of an affiliated group of companies consisting of the Sivyer Steel Casting Company, Federal Malleable Company and Interstate Drop Forge Company, all of Milwaukee.

Distributor Notes from Barber-Greene

An office has been opened at 527-528 Merchants National Bank Bldg., Cedar Rapids, Ia., by the Barber-Greene Company of Aurora, Ill., manufacturers of ditchers, loaders, conveyors, coal equipment, etc. Mr. Jack Marson of the Barber-Greene Company will have supervision of this office. Mr. Marson has been with the Barber-Greene Company for a number of years.

Another branch office under the supervision of Mr. Marson has been opened at 1106 Nicholas St., Omaha, Neb. Mr. W. E. Toole is in direct charge of this office.

W. S. Dickey Clay Mfg. Co. has consolidated the Atlanta and Birmingham offices, and mail should hereafter be addressed to P. O. Box 1592, Birmingham, Ala.

Whitcomb-Baldwin Combine Forces

The George D. Whitcomb Company, an organization engaged for the past fifty years in developing a complete line of gasoline, oil and alcohol burning locomotives for railway, industrial and contracting activities, and the Baldwin Locomotive Works of Philadelphia, known as one of the largest steam locomotive builders in the world, have combined forces to the extent that a substantial interest in the Whitcomb Company has been purchased by the Baldwin Company.

There is an ever increasing demand for internal combustion engines for the larger locomotives. The George D. Whitcomb Company is now building straight gear driven machines powered by gasoline, distillate and oil in sizes up to fifty tons, developing draw bar pulls in low gear, up to 25,000 lb. They have developed gas and oil electric locomotives up to 100-ton sizes and can furnish railway locomotives with a maximum draw bar pull of 50,000 lb.

The Baldwin Company will handle the products of the Whitcomb Company through its foreign representatives in all parts of the world, and through its domestic offices will handle the railway field in the United States.

The combination of the two corporations places them in a position to build every size of steam, gasoline, alcohol, distillate, Diesel, gas-electric or Diesel electric locomotive. The works of the Geo. D. Whitcomb Company are located at Rochelle, Ill.

1929 Ushers in New Engines and New Plant of Waukesha Motors

The new engines and power units developed during 1929 by the Waukesha Motor Company, Waukesha, Wis., will receive adequate service by reason of the new buildings now placed in operation for the benefit of users of the Waukesha products.

Quoting from a statement of the president of the company, Mr. H. L. Horning: "New plant extensions increase our floor area 100 per cent and give additional production facilities for both our new engines and those which we have been building for some years past. Proving laboratories for both research and production engines are now starting operation. * * * Greater stocks and prompter shipments are assured by our new buildings."

Sales offices and representatives for the Waukesha Company are located in New York, San Francisco, Tulsa, Oklahoma and Houston, Texas.

Sullivan Spader Wins in "Blindfold Test"

Hoag and Rollins were tunneling in hard clay at Toledo. They knew air clay diggers could beat hand labor. They didn't know which diggers were speediest.

So they tried a "blindfold test." Four men in the heading got four different clay spades. Clay spattered over the names. The men exchanged tools. When the shift came out of the hole—the superintendent asked which spade they wanted.

All voted for the same tool. The superintendent scraped off the clay and recorded the name, "SULLIVAN." After one week of testing, the contractors standardized on Sullivan Spaders.

Sullivan Spaders are hard on clay, but easy on men. They are balanced, smooth-running, and powerful. They will save you money.

Send for Catalog 6081-N.

Useful Equipment Information

Watch these trade announcements for new and improved equipment

By writing the manufacturers named and mentioning this magazine, copies of the following catalogs will be sent to you without obligation

TRADE PUBLICATIONS

Pull-Shovel.—Koehring Company, Milwaukee, Wis., has just issued a very attractive broadside descriptive of the Koehring Pull-Shovel. The pull-shovel boom, instead of being hinged to the turntable casting, is hinged to a separate casting which forms the base of the jib frame. It is built in two sizes and three models; ⅞ and 1¼ cu. yd. dippers, line-of-plate struck measure. In actual operation, heap loads of 1⅛ and 1⅝ cu. yd. can be handled. Many outstanding desirable features are pointed out in this bulletin, which also gives working dimensions and specifications. Write to the manufacturer for a copy, using the name of our publication.

Gunite.—Write to the Cement Gun Construction Company, 537 S. Dearborn St., Chicago, for full information concerning this product. They will be pleased to furnish particulars and make contractors' estimates if desired.

Sani-Dri.—For all types of municipal buildings, schools and recreational centers having swimming pools, the Chicago Hardware Foundry Co. (Electrical Division), North Chicago, Ill., will be pleased to furnish complete information concerning the installation of Sani-Dri the modern, sanitary method of hair drying to prevent illness and relieve congestion in the shower rooms. Kindly give the name of our publication if writing for information.

Fiber for Sweepers.—The Huntsville Fiber & Veneer Works, Huntsville, Ala., will be pleased to send you a copy of their attractive booklet "The Story of Huntsville Hickory." This booklet gives the complete history of the growing of hickory and manufacturing process of turning it into the "Faultless Hickory Fibers" for long-life street sweepers. It contains much interesting information concerning fiber equipment, as well as about the service this company is able to render. If writing manufacturer, kindly give the name of our magazine.

Air Pump.—The Indiana Air Pump Company, Indianapolis, Ind., will be pleased to send you information concerning the air lift method of pumping wells. The catalog issued by this company stresses the dependability of this method with low depreciation and repairs. They will be pleased to send you catalog or to make quotations if you send them data and water requirements.

Paving Survey & General Highway Conditions.—To obtain an up-to-date picture of the present status of the highway business, the National Paving Brick Manufacturers Association appointed a committee of engineers to investigate the general economic status of the urban and rural highway conditions of the country. The result of this investigation is now presented as a report and may be secured by writing the association, 1245 National Press Bldg., Washington, D. C. William H. Connell was chairman of the engineering commission conducting the investigation. The report is well indexed and lists a wide range of topics such as: Highway expenditures; Highway cash dividends; Administration of the highway business; Planning highway systems; Signals; Trend in construction; Traffic and maintenance data; and an exhaustive study of the value of vitrified brick pavements. An informative and interesting book. If writing National Paving Brick Manufacturers Association for copy, kindly give the name of our publication. Ask for "Report of Investigations of Paving and General Highway Conditions."

Cement Lined Pipe.—The American Cast Iron Pipe Co., Birmingham, Ala., issued a book called "Cement-lined Cast Iron Pipe," describing the method of placing thin lining of cement in standard cast iron pipe to prevent tuberculation and reduce friction loss. If requesting copy of this book, please mention our magazine.

Centrifugal Pumps.—For a complete catalog on this equipment write to the DeLaval Steam Turbine Co., Trenton, N. J., asking for Catalog B. This is a very handsome 72-page catalog, discussing single stage and multistage pumps, for general water service, power plant service, including boiler feeding, condenser circulating and hot-well service, water works service, including main pumping units and booster, filtration and flushing service. Pumps for sewage, drainage and irrigation, elevator and hydraulic pressure, marine or fire service, oil, pulp, acid, etc. The catalog is beautifully illustrated and gives cross sectional drawings showing details of pumps. There is a section on manufacturing methods and materials, and one on testing, also just what information should be furnished in seeking plant for individual requirements. Manufacturer will be pleased to send you a copy of this informative book. Kindly mention our magazine.

Forged Steel Gate Valves.—A very handsomely bound book is catalog No. 10, issued by the Darling Valve & Mfg. Co., Williamsport, Pa., containing 32 pages filled with illustrations and giving prices and specifications of this product. Each valve is given a rigid test before leaving the factory and is subjected to hydraulic pressure equal to its rated tested pressure. If valves of standard dimensions and design cannot be used, company will be pleased to be consulted concerning deviations. If writing manufacturer, give the name of our publication, please.

Cast Iron Pipe.—For complete information on McWane Cast Iron Pipe, "what it is," "what it does," fields it serves, types, specifications, quality, special features, etc., are all told in a 54-page booklet issued by the McWane Cast Iron Pipe Co., Birmingham, Ala. The territory west of the Rocky Mountains is served by the plant at Provo, Utah, called the Pacific States Cast Iron Pipe Co., of which Mr. J. P. McWane is president. Write to the manufacturer for a copy of this booklet on McWane precalked joint cast iron pipe and fittings. Kindly mention the name of our paper.

Rawhide Packing.—Mabbs Hydraulic Packing Company, 431 S. Dearborn St., Chicago, will be pleased to send you information concerning sizes, weights and uses of their rawhide packing. This packing is practically anti-frictional, will not cut or score metal surfaces and never becomes hard or glazed. It works equally well on centrifugal or reciprocating pumps. This packing has been found of service for the marine business, in cotton gins, for mining purposes and in oil fields on pumps and wells. It is put up in standard tin pails of from 5 to 50 lb. and in kegs and barrels of 100 and 200 lb. This company makes a specialty of rawhide washers for packing the stems of water meters. They can be ordered by meter companies in 100,000 lots. Write the manufacturer for further information, kindly mentioning our magazine.

Fire Pumps.—Bulletin No. 104 has just been issued by the Chicago Pump Co., 2300 Wolfram St., Chicago, fully illustrating and describing their electric centifugal fire pumps. Booklet contains blue print drawings and a list of installations. If writing manufacturer for copy kindly mention our magazine.

Cast Iron Soil Pipe.—A very interesting booklet, containing twelve pages of beautiful modern buildings, has been

WATER WORKS

Detroit, Mich.
1,500,000 gallons

Elevated Tanks *for* Municipal Water Works

Pittsburgh-Des Moines steel tanks are especially designed for municipal water works, and have furnished water storage to many communities for over thirty years.

An elevated water storage tank takes care of the water consumption during the peak hours and insures a constant pressure at all times. It eliminates fire hazards when repairs are being made at the pumping plant.

We build complete water works system, including pipe lines, reservoirs and filtration and purification plants.

Protect yourself!

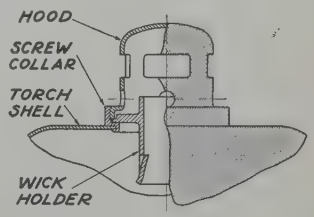
with simple and direct LIGHT

from a dependable source

in other words always use the

TOLEDO TORCH

PRETTY colored lanterns may get you by with cautious drivers, if you hire a watchman to keep them on the job. But it's the reckless ones who cause all the accidents. With them the use of uncertain signals, such as red lanterns, is a needless risk for you to take, especially when it is so much more costly than using TOLEDO TORCHES.



The New TOLEDO TORCH is dependable in all kinds of weather, is very economical in the use of fuel, and is never molested by petty thieves. The secret of its great success lies in the new ECONOMY BURNER. (Patents Pending)

IT is the only burner that will give you satisfactory service at all times. Observe carefully its construction, and *insist on having the genuine.* Similar looking imitations do not compare in performance.

Ask for the *'Champion'*

"the harder it blows the better it burns"

Made only by

THE TOLEDO PRESSED STEEL CO.
TOLEDO, O.

issued by The Soil Pipe Association, Birmingham, Ala. The booklet is an announcement of the willingness of this association to guarantee cast iron soil pipe for 100 years, or for the life of any building in which it is used. If writing the association for information concerning this proposition, kindly use the name of our publication.

"Water Services that Serve" is the title of a brochure just issued by the Copper and Brass Research Association for distribution to municipal authorities, engineers and contractors. The booklet gives general data on copper and brass tubing and pipe with special reference to copper for use in service pipe between water mains and house lines. Tensile strength, bursting pressure tests, sizes, lengths and general data about installation are included in tables and explanatory paragraphs. If writing the assocation for a copy of this booklet, kindly mention our magazine.

Boyer Riveting Hammers.—A very attractive bulletin, SP-1694, has just been received from the Chicago Pneumatic Tool Co., 6 E. 44th St., New York, covering in a very thorough manner this equipment. The booklet contains the announcement that after Feb. 1, 1929, all Boyer riveting hammers will be furnished with an improved hardened and ground valve unit, unless specifically ordered with the soft valve block. Write for a copy of the bulletin, kindly mentioning our magazine.

Pump Control.—Bulletin No. 140 has been issued by the Chicago Pump Co., 2300 Wolfram St., Chicago, listing complete pump control units for operating pumping plant. Control panels, control boards, float switches, automatic alternators, etc., are illustrated and described in this 12-page, loose leaf style bulletin. This will be an aid in selecting the proper pump control. . Manufacturer will be pleased to send you a copy, kindly give the name of our publication, if writing for copy.

Water Softeners and Purifiers.—The Graver Corporation, East Chicago, Ind., has issued a little booklet illustrating and describing the various types of water softeners and filters, as well as steel storage tanks. Hot process, cold process, zeolite and lime-zeolite treatment, for industrial plants, ice plants and railroads, as well as the smaller types for household purposes are described. More complete bulletins devoted to any special type are specified by letter. Filters for industrial and municipal works and swimming pools also receive attention. If requesting a copy of this booklet, kindly give the name of our magazine.

Dipper Trip.—A folder from the Morin Mfg. Co., 896 Main St., Holyoke, Mass., manufacturers of appliances and improvements, gives illustrations and detailed information about their Universal-Semi-Automatic Dipper Trip. This dipper trip may be adapted to any make or type of shovel, steam or air, gasoline, diesel, electric, or gas-electric and gas plus air. The outstanding features of this appliance set forth in circular are ease of operation and elimination of lost motion. Write for folder describing this equipment and also the friction-type dipper trip and tag line winder for gasoline, diesel and electric, and gas-electric and gas plus air shovels. If writing manufacturer kindly mention our magazine.

Paved Invert Culverts.—"Paving the Culvert to Combat Erosion" is the title of a comprehensive pamphlet issued by the Armco Culvert Mfrs. Association, Middletown, O. This product is designed for use where culverts carry highly sedimentary streams, on steep grades, in mountainous country, storm sewers, etc. The booklet illustrates in detail the paved invert and described tests applied in developing it. The culvert must be made to withstand hydraulic traffic within and vehicular traffic from above. The booklet described the Armco system. Kindly give the name of our publication if writing manufacturer for literature.

For Water Works Campaigns.—Of interest to city officials and water works engineers in promoting campaigns for securing water works or renewals is the booklet issued by the Cast Iron Pipe Publicity Bureau of the Cast Iron Pipe Research Association, 122 S. Michigan Ave., Chicago. It is called Community Advertising, and shows colored reproductions of posters, street banners, direct mail literature and newspaper advertising to be used in securing this type of improvements for the home town. This campaign material will be furnished free by the association to aid in the cause of water works. Write for a copy of Community Advertising and find out just how much free help is available in aiding you with your problems. Kindly mention the name of our publication when writing.

Automatic Valves.—Catalog No. 24 has been issued by the Golden-Anderson Valve Specialty Co., Pittsburgh, Pa., to present with illustrations and descriptions their well known automatic cushioned valves for steam and water service and to call attention to many new styles of valves. The catalog contains 200 pages, well printed on enamel paper, with a complete index. A very useful and attractive catalog on valves. The Pittsburgh address of the Golden-Anderson Specialty Co. is Fulton Building. Kindly mention our magazine, if writing.

Gasoline Hoists.—The American Hoist & Derrick Co., St. Paul, Minn., has just issued an eight-page folder concerning the "American" silent chain drive gasoline hoists for general hoisting work. The booklet gives specifications, outstanding features and construction details. The engine and hoisting drums are mounted on a cast iron frame insuring absolute alignment of all working parts. The unit is entirely self-contained.

Monarch Tractors.—Wise planning highway officials, who were snowed under during the past winter, will look to the snow removal machinery in time to have it on hand next year when the first snow flies. The Allis-Chalmers Mfg. Co., Milwaukee, Wis., will be pleased to send you literature concerning the outstanding features of the Monarch "75" with V-type plow for keeping the roads clear in the heaviest snows.

Expansion Joints.—Write to the Philip Carey Co., Lockland, Cincinnati, O., for full particulars concerning their Elastite Expansion Joint, which requires only ordinary tools and workmen for installation. If writing manufacturer for literature concerning this product, kindly mention our publication.

Snow Removal, 1929.—This is the title of a very attractive booklet which the Caterpillar Tractor Co., San Leandro, Calif., has issued looking forward to the work and equipment which will be needed for next winter to keep the roads clear. Removal in Cities; Cost of Removal; America's Snowbelt and Loss to Business are some of the topics treated. Equipment for meeting these problems is illustrated and described. Send for a copy of this booklet and plan to meet this situation before it becomes a problem. Kindly mention our magazine, if writing manufacturer.

Well Systems.—Write to Layne & Bowler, Inc., Memphis, Tenn., or any of their representatives located in all the principal cities, for information about the Layne Water Well Systems. They will be pleased to give you the benefit of their long years of experience in this field.

Leadite.—A self-caulking material for cast iron pipe manufactured by the Leadite Co., Land Title Bldg., Philadelphia, Pa. The manufacturer will be pleased to send you detailed information and records of pipe lines where this product was used. If writing, kindly give the name of our paper.

Sludge Removal.—The Link-Belt sludge collector is recommended by the manufacturer for its sturdy mechanism and reliability in removing sludge from sedimentation tank. An excess of accumulation of sludge will not slow down or stop operation. For complete information concerning this or other sewage treatment plant equipment, write to the Link-Belt Co., 300 W. Pershing Road, Chicago. Kindly mention our magazine.

Stops and Water Works Products.—For information on the full line of stops and other products for water works, write to the Mueller Co., Decatur, Ill., for catalog. They will be pleased to furnish information about water works companies using their curb stops and corporation stops for standard equipment.

GOLDEN-ANDERSON

GOLDEN-ANDERSON
Patent Automatic Cushioned Controlling Float Valves

Adapted to automatically maintain a uniform water level in feed-water heaters, tanks, reservoirs, and pans. Very sensitive.

Operating on ½-in. to ¾-in. variation. No. exhaust or expensive water waste. Can be furnished for hot or cold initial water supply. Reliable and dependable under varying pressure.

Sizes ½ in. to 24 in.

Automatic "Cushioned" Controlling Altitude Valves

Cushion All Water Surges

Automatically maintain a constant stage of water in reservoirs, tanks and standpipes.

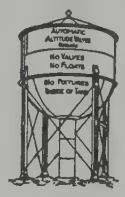
They do away with the annoyances of Freezing Valves and Float fixtures inside of the Tanks or Floats and Fixtures outside of Tanks. "Three Ways of Closing These Valves."

1st—Automatically, by water.
2nd—By electricity, if desired.
3rd—By Hand.

May also be arranged to automatically close when a break occurs in the mains. When necessary they may be so connected as to "work both ways" on a single line of pipe.

The double cushion effect of air and water eliminates water hammer.

There are no dangerous surges to burst water mains. **Write for details.**



REMEMBER
Valves cushioned at all times by air and water. No water hammer or bursting mains.

"Made with stop starter attachment for centrifugal pumps."

Golden-Anderson Valve Specialty Co.
1385 Fulton Bldg., Pittsburgh, Pa

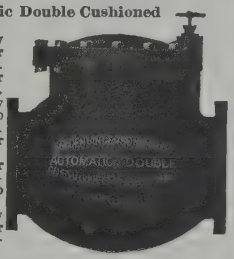
GOLDEN-ANDERSON
Patent Automatic Cushioned Water Relief Valves

1. Automatically relieve excess pressure.
2. Prevent stress, strain and bursting of mains.
3. Correct mechanical construction.
4. Perfect air and water cushioning.
5. No metal-to-metal seats. No hammering or shocks.
6. Angle and globe pattern. Sizes 3 to 24-in.

GOLDEN-ANDERSON
Pat. Automatic Cushioned Water Pressure Regulating Valves

1. Maintain a constant reduced pressure regardless of fluctuations on high pressure side.
2. Perfectly Cushioned by water and air. No metal-to-metal seats.
3. The best valve made for maintaining a constant low pressure where consumption is continuous.
4. Operates quickly or slowly as required—No attention necessary.
5. Positively no hammering or sticking. Sizes to 24 in.

GOLDEN-ANDERSON
Pat. Automatic Double Cushioned Check Valves

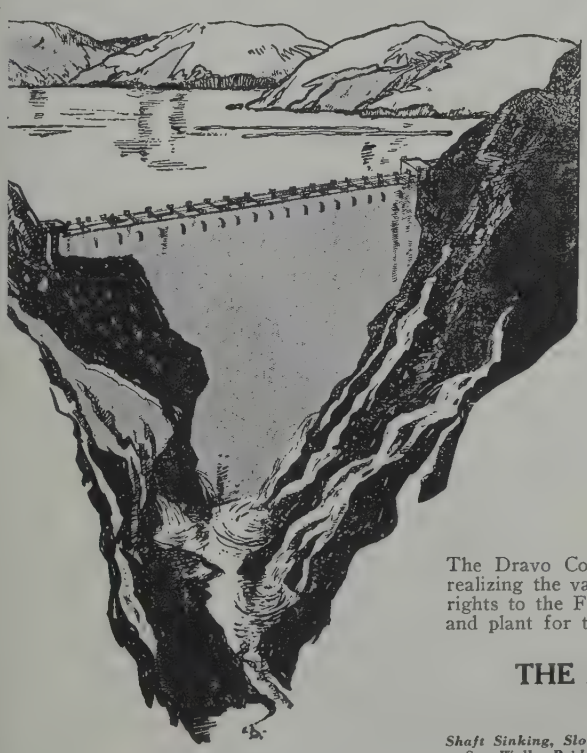


1. Especially adapted for Water-Service.
2. For High or Low Pressure.
3. Thoroughly Cushioned. No Chattering. Hammering, or Sticking.
4. Globe or Angle Patterns up to 24 in.
5. Especially adapted for hydraulic elevator service.

GOLDEN-ANDERSON
Pat. Automatic Cushioned Water Float Valves

1. Automatically Maintain Uniform Water Levels in Tanks, Standpipe, etc.
2. Instantly Adjusted to Operate Quickly or Slowly.
3. Floats Swivel to any Angle—Most Satisfactory Float Valves known.
4. No Metal - to-Metal Seats—No Water Hammer or Shock.
5. Cushioned by Air and Water.

Sizes ½" to 24".



Have You a Leakage Problem?

Francois Cementation Process

The surest and most economical method of overcoming difficulties due to the presence of water or bad ground.

The cementation process—the specialized high pressure injection of liquid cement mixtures into cavities, fissures, or cracks—has been developed to a high degree in Europe, and more particularly in Great Britain by the Francois Cementation Company, who have a long list of successful contracts to their credit, including internationally known structures.

Some features of the Francois Process are:

Grout is under perfect control;
Pressures to 3,000 pounds per square inch if required;
Chemical processes for a hundred and one different cases;
Wide experience in many years specialization.

The Dravo Contracting Company, after many years successful work and realizing the value of specialized grouting, have acquired the sole American rights to the Francois patents, and at their disposal is a highly skilled staff and plant for the execution of contracts.

THE DRAVO CONTRACTING COMPANY
PITTSBURGH, PA.

Shaft Sinking, Slopes, Tunnels, Pneumatic Caissons, Submarine Construction, Locks, Dams, Sea Walls, Bridge Piers, Steel Barges, Steel Towboats, Inland Waterway, Floating and Terminal Equipment, Steel Headframes, Steel and Concrete Tipples.

Meter Repair.—For repairing or testing any make or size of water meter, write to the Reading Meter Repair Co., Inc., Reading, Pa., for prices and particulars. They will be pleased to furnish information concerning any hydraulic supplies and equipment.

Deep Well Power Pump.—The United Iron Works, Inc., Springfield or Kansas City, Mo., will send upon request literature of interest on the "Pomona" double stroke deep well power pump. Booklet contains much interesting information on deep well pumping and pumping problems. If writing for literature, kindly mention our magazine.

Sanitary Specialties.—For information on a complete line of special sanitary products manufactured by the Servicised Products Corp., address the company at 6051 W. 65th St., Chicago. Among these products are bituminous rope, sewer compound, sewer belts, asphalt liner slabs, etc.

Road Oil.—Standard Road Oil is offered by the Standard Oil Co. of Indiana, 910 S. Michigan Ave., Chicago, for obtaining dustless dirt or gravel roads and giving a waterproof roadway. Write to the company for information on application.

Hydrants, Valves, Etc.—Write to the Columbian Iron Works, Chattanooga, Tenn., for descriptive literature of the Columbian Fire hydrants, Gate valves, Valve boxes, Hydrant extension sections, or other water works equipment. We would appreciate it if you would mention our publication if asking for information.

Cast Iron Pipe.—United States Cast Iron Pipe & Foundry Co., Burlington, N. J., will be pleased to send you literature explaining the differences between the deLavaud Cast Iron Pipe and other types of pipe. This is a centrifugally cast pipe in which the graphite particles are finely divided and evenly spread.

Pipe Cutting Tool.—A folder from the Tucker Company, Inc., 75 Murray Street, New York City, gives a detailed description and price list of parts in all sizes of their cutter for cast iron pipe. This tool can be used in any ordinary trench without extra excavating. It will cut a piece one inch long or more at any point without starting joints or otherwise disturbing the main, and will make a clean cut in a gas or water main in the trench. Write to the Tucker Company for literature and price list of the Anderson Pipe Cutting Tool. In writing, kindly give the name of our magazine.

Wrought Iron Pipe.—"The Installation Cost of Pipe" is the title of a Bulletin issued by the A. M. Byers Company, Pittsburgh, Pa., containing cost data and full particulars concerning this product and its uses. Ask for Bulletin No. 38, giving the name of our magazine.

Compressors.—The Sullivan Machinery Company, 122 S. Michigan Ave., Chicago, Ill., has issued a new handbook on Compressed Air Practice, containing numerous suggested uses for compressed air as an aid to speeding production and improving products. It also contains helpful information concerning piping, lubrication and the care of compressed air equipment. The manufacturer will be pleased to send a copy of this book upon request, and we would appreciate it if you would mention our publication if writing.

Automatic Control Valves.—The Ross Valve Mfg. Co., Inc., Archibald St., Troy, N. Y., will be pleased to furnish you with particulars regarding their automatic pressure control valves for feed water filters, portable fire hydrants, hydraulic engines, hydraulic booster pumps, etc. Write for information, giving the name of our publication.

Clay Pipe.—The Clay Products Association, Conway Building, Chicago, makers of vitrified clay pipe, will be pleased to send you full information regarding this product.

Meters — Gauges — Valves. — Information on complete equipment for filtration plants may be secured by writing the Simplex Valve & Meter Company, 6749 Upland Street, Philadelphia, Pa. The Simplex Rate of Flow Controller is adaptable to large and small filter plants from 30-inch effuent to 3-inch. The Simplex Venture Type Meter indicates, records and totalizes the rate of flow, and the Simplex Filter Gauges may be had in many combinations of Indicating, Recording and Totalizing. If writing for particulars on this equipment, kindly mention our nagazine.

Filtration Plants.—Norwood Engineering Company, Florence, Mass., will be pleased to send you full particulars regarding the Norwood Municipal Filtration Plants. Kindly give the name of our publication if requesting information.

Compressors, Drill Sharpeners, Pneumatic Tools.—The Sullivan Machinery Company, 122 South Michigan Avenue, Chicago, Ill., will be pleased to send you a copy of their new eight-page folder, Form 2007, calling special attention to their portable air compressors, mounted to suit your requirements; drills, spaders, hoists and sharpener—all illustrated and described. Catalogs will also be sent upon request, write for information. Kindly mention our magazine, if writing manufacturer,

Meter Boxes.—The Ford Meter Box Company of Wabash, Indiana, have a special bulletin on the Ford Type S Meter Boxes for "warmer climates." Meters can be set or removed in an instant. The Ford standard testers can be adapted for testing meters in a series, each meter clamped in separately and the work economically and conveniently handled.

Water Meters.—Write to the Badger Meter Manufacturing Company, Milwaukee, Wis., for detailed bulletin on their complete line of meters, ranging in size from the smallest disc to the 12-in. turbine. This information will point out the way to reduce your pumping costs, by the use of the Badger Turbine Meter at the pumping station and the meters on the service lines. Many changes were made during the past year to increase efficiency and serviceability. If writing for literature, kindly mention our magazine.

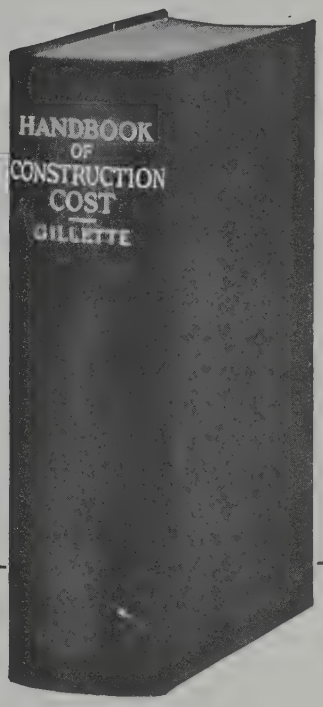
Excavator.—Write to the Bucyrus-Erie Company, South Milwaukee, Wis., or Erie, Pa., for bulletin on their D-2 Diesel Drag-Shovel. This shovel is built for the hardest work at a minimum cost. Easily convertible to clam-shell-crane, shovel or dragline. Manufacturer will be pleased to furnish you with performance records of this equipment.

Dosing Tank Counter, Sewage Tees, Nozzles, Etc.—Bulletin No. 100, issued by the Pacific Flush-Tank Co., 4241 Ravenswood Ave., Chicago, contains full descriptions, table of weights and price list of this equipment. The new dosing counter for checking the amount of sewage treated by keeping count of the number of times the dosing tanks have discharged may be mounted on the roof of the tank or attached by brackets to the side wall. The counter is protected by a weather-proof cover and has been operated in all kinds of weather. For complete information about the Marley Sewage Tees for sprinkling filter beds and nozzles of the threaded spindle type, lock spindle type and spindle and half spray plug, write to the manufacturer. If requesting literature on this equipment, we would appreciate it if you would mention our magazine. The New York office of this company is at 9 Park Place.

Industrial Engines.—Bulletin No. 201 has been issued by the Weber Engine Company, Kansas City, Mo. This is a horizontal, 2-cycle, single cylinder, medium compression engine, of comparatively light weight, designed and constructed to insure the greatest strength and rigidity. For users requiring power units of 30-hp., 40-hp., 60-hp., 80-hp., 100-hp. and 125-hp. it affords a thoroughly reliable, compact and economical oil or gas engine of great simplicity. This engine is adaptable for water, sand, drainage or irrigation pumps, electric generators, air compressors, rock crushers, pipe line machinery, mills and industrial plants. The bulletin contains illustrations and cross-sectional drawings and full description. Write for a copy of this bulletin, kindly mentioning our magazine.

What's the Last Step Before

"I Give Up" ?



In your experience did a particularly tough estimating problem ever have you on the verge of giving up? Whether you did or not you realize that "I give up" usually means the other fellow gets the job.

This book on Construction Costs was written to prevent most of those cases in which the contractor, estimator or engineer feels baffled. When you realize that you are never really stumped until after you have referred without success to Gillette's "Handbook of Construction Costs," you'll recognize the value of this book. Because you'll find in most cases that the Handbook quickly refreshes your mind or furnishes new information on every element of construction expense.

We'd like you to go through it on our recommendation. May we send the book postpaid for ten days, within which you will return it or decide to keep it? Send the coupon.

Francois Cementation Process.—The Dravo Contracting Co. have acquired the sole American rights to the Francois patents, and have a highly skilled staff who will be pleased to help you with your problems. This method of grouting covers chemical processes for a hundred and one different cases, the engineers of the Dravo Company are ready to help you solve your problems. Write to their company at Pittsburgh, Pa., mentioning our magazine.

Hydrants, Valves, etc.—Full particulars for supplies needed by water works and fire departments will be sent upon request by the Bourbon Copper & Brass Works Co., 618 E. Front St., Cincinnati, Ohio, manufacturers of fire hydrants, gate valves, and extension valve boxes. Write for their catalog, giving the name of our magazine.

Sewer Cleaning Machine.—W. H. Stewart, whose factory is at Walkerville, Ontario, has branches in St. Louis, Mo., Jacksonville, Fla., and Boston, Mass., so that his patrons on this side of the border may be served without paying duty. Literature describing his sewer and conduit rods will be furnished on request. Rods will be shipped on trial. If writing to Mr. Stewart for information concerning his equipment kindly mention our publication.

Zeolite.—"Softening Municipal Water Supplies by the Use of Zeolite" is the title of a bulletin issued by the Zeolite Chemical Company, 140 Cedar Street, New York City. This booklet describes Green Sand, a natural base exchange Zeolite Mineral, used for the purpose stated. Write to Mr. R. E. Wagner of the Zeolite Company for a copy of this bulletin. If writing, we would appreciate it if you would mention this magazine.

Trimo.—The trade name by which the wrenches manufactured by the Trimont Manufacturing Company, Inc., are known. These pipe wrenches are made with a braced frame to stand the hardest strain, with hard biting jaws that can be easily renewed, and the heat treated steel handles assure tremendous strength. Write for detailed information and prices to Roxbury (Boston), Mass., mentioning the name of this magazine.

Hydrants and Valves.—The Mathews Fire Hydrants, built for easy installation and so that an extension section may be used to adapt them to new grades, are described in literature of the R. D. Wood & Co., Philadelphia. If you will write to Mr. C. Becker of this company he will gladly send you full information about their sand-cast and "sand-spun" centrifugal cast iron pipe fittings, valves, boxes and hydrants. Please use the name of our magazine if writing.

Chemicals.—The Hooker Electrochemical Company of 25 Pine St., New York City, or Tacoma, Wash., will be pleased to send you literature concerning the Hooker chemicals. Among the products of this company are listed: Caustic Soda, Liquid Chlorine, Bleaching Powder, Muriatic Acid, Monochlorbenzine, Paradichlorbenzine, Benzoate of Soda, Benzoyl Chloride, Ferric Chloride, etc. Plants are located at Niagara Falls and Tacoma. If writing manufacture, kindly give the name of our paper.

Meter Boxes.—If you will write to H. W. Clark Company, Mattoon, Ill., they will be pleased to send you catalog No. 24, giving full information in regard to their meter protection boxes, constructed of bronze, with locking device and assuring safeguard from climatic conditions. Construction provides for access for repair work or replacements. If requesting copy of catalog, kindly mention our magazine.

Pumps. — New Catalog containing complete information on centrifugal pumps, plunger pumps, and deep well power heads may now be obtained by writing the American Well Works, Aurora, Illinois. Their engineering department will be pleased to discuss your needs with you, recommending the best equipment for your purposes. Kindly use the name of our publication if writing for information.

Disposal Plants. — Fairbanks-Morse and Co., Chicago, or any of their branch offices in the principal cities will be pleased to furnish complete details concerning their F-M Trash pumps for handling unscreened sewage direct from sewers. Write for information, giving the name of our publication.

Cast Iron Pipe.—National Cast Iron Pipe Company, Birmingham, Ala., will be pleased to send you particulars in regard to cast iron pipe for water and gas. Pipe made by sand cast and deLavaud centrifugal processes, also fittings and 2-in. cast iron service pipe. Branches in the principal cities.

Filtration Plants.—The Norwood Engineering Company, Florence, Mass., has much information on the installation of filtration plants which they would be pleased to send you if interested in municipal plants. Write for records of Norwood Municipal Filtration Plants. Kindly mention our magazine.

Reinforced Concrete Pipe.—The Lock Joint Pipe Company, Ampere, N. J., would be pleased to send you full particulars concerning Lock Joint Reinforced Pressure Pipe; its permanence, high carrying capacity, tightness, expansion joints, etc.

Sluice Gates.—Coldwell-Wilcox Company, South Water St., Newburg, N. Y., manufacturers of sluice gates, sheer, flap and butterfly valves, flexible joints, etc., will be pleased to send you full information concerning any of these products. If writing for catalog, kindly mention our paper.

Concrete Pipe.—Write to the Asphalto-Concrete Corporation, 1440 Broadway, New York City, for full information and manufacturing rights for the use of the Moir-Buchanan Centrifugal Process of making concrete pipe. Low manufacturing costs, low laying costs, high density, low absorption and long pipe life are features of this product.

Chlorinator.—The Paradon Manufacturing Company, Arlington, N. J., has issued Bulletin W-22, describing in detail the Paradon Chlorinators for city and private water and sewage systems, industrial plants and swimming pools. If writing for a copy of this bulletin, we would appreciate it if you would mention our magazine.

Gas Main Stopper.—The Safety Gas Main Stopper Co., 523 Atlantic Ave., Brooklyn, N. Y., will be pleased to furnish you with particulars on the use of the Goodman Cylindrical Stopper, to stop the flow in sewers. Write for information, giving the name of our publication.

Filter Sands and Gravel.—To meet the most rigid specifiactions on this product write to the Northern Gravel Company, Muscatine, Ia., for information on their "Standard."

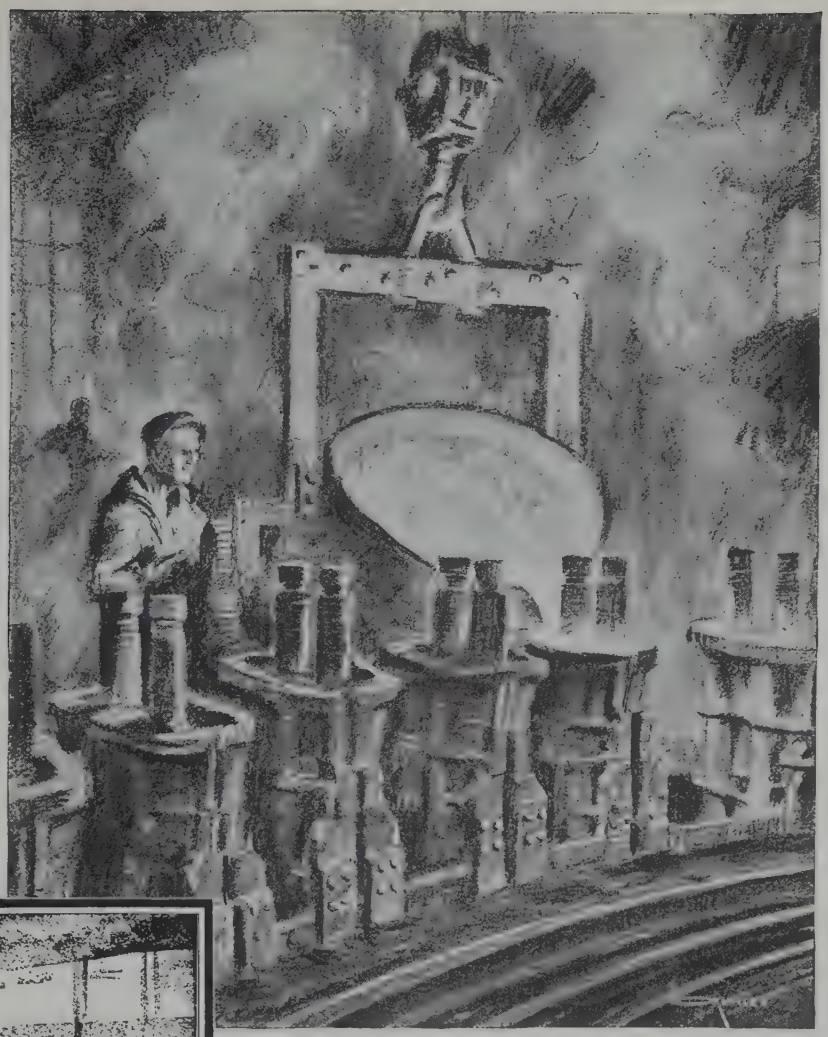
Castings.—Write to the South Bend Foundry Company, South Bend, Ind., for information concerning their patented chilled manhole covers. Information furnished on all kinds of gray iron castings.

Valve Housings.—S. E. T. Valve & Hydrant Company, 50 Church St., New York City, will be pleased to send, upon request, descriptive literature on their cast iron sectional valve housings, built in different sizes and depths. This company makes a complete line of municipal street castings and will furnish catalog if desired.

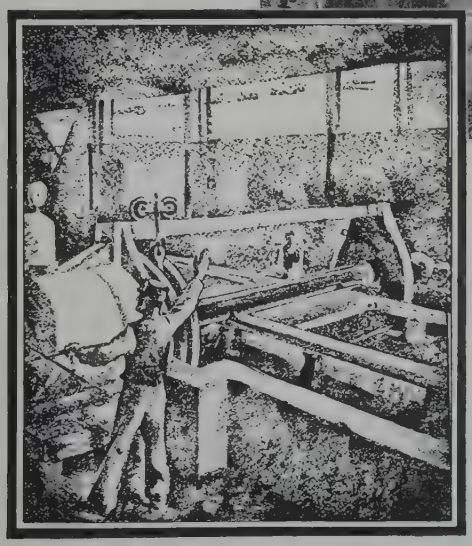
"The Cleaning of Water Mains."—This is the title of a booklet issued by the National Water Main Cleaning Company, 32 Church St., New York, describing the method so successfully used by them for the past twenty years. Write for a copy, giving the name of our magazine.

Chlorination.—Wallace & Tiernan, Newark, New Jersey, manufacturers of chlorine control apparatus will be pleased to send you full particulars in regard to the sterilization of water by their method, and to furnish you with record of cities where their apparatus is being used. If writing for information, we would like to have you mention our magazine.

SAVE YOUR TIME! USE OUR SERVICE! Prices on equipment, names of manufacturers or their catalogs will be cheerfully furnished to you by our Service Department. Write Municipal News and Water Works, 221 E. 20th St., Chicago.



Every length of cast iron pipe must pass a severe hydrostatic test as shown below. The pipes are brought into a testing press, sealed at each end and pumped full of water at a pressure as high as 300 lbs. per sq. inch according to the size of pipe.



NOWHERE is scientific control more in evidence than in the foundries of modern cast iron pipe manufacturers. Today, for example, the percentages of carbon and phosphorus necessary to produce greatest strength are known and accurately controlled. Today, the pouring and cooling rates of cast iron pipe are checked with extreme care, and the thickness and diameter of every pipe are tested with precision instruments. It is a noteworthy fact that the manufacture of cast iron pipe today claims a leading place in the ranks of *modern* American industry.

* * *

The Cast Iron Pipe Research Association is a service organization of leading pipe founders, formed to promote the scientific improvement and proper use of Cast Iron Pipe. Pipe bearing the Association "Q-check" mark may be obtained from the following: American Cast Iron Pipe Co., Birmingham, Ala.; James B. Clow & Sons, 219 N. Talman Ave., Chicago, Ill.; Donaldson Iron Company, Emaus, Pa.; Glamorgan Pipe and Foundry Co., Lynchburg, Va.; Lynchburg Foundry Company, Lynchburg, Va.; National Cast Iron Pipe Company, Birmingham, Ala.; United States Cast Iron Pipe & Foundry Company, Burlington, N. J.; Warren Foundry and Pipe Company, 11 Broadway, New York City.

CAST Q IRON

The "Q-check" symbol shown above has been adopted as the trade mark of The Cast Iron Pipe Research Association. Insist on this "Q-check" mark when specifying cast iron pipe for gas, water, sewer, or industrial service.

For complete information write to The Cast Iron Pipe Research Association, Thomas F. Wolfe, Research Engineer, Peoples Gas Building, Chicago.

DISTRIBUTOR NEWS

The Distributor's Department in the Gillette Construction Group

Kalbfleisch Corporation Celebrates Century in Chemical Industry

In March the entire organization of the Kalbfleisch Corporation of New York city, together with a few invited guests, gathered at the Fifth Avenue Restaurant to enjoy the company's century dinner and to do honor and tribute to the house of Kalbfleisch.

Mr. Hays H. Clemens, a director of the company, served as toastmaster. Mr. A. B. Savage, vice-president and treasurer outlined the development of the company, James W. Prendergast, general counsel, described operations at the various plants, six in number, stretching from Connecticut to Louisiana, and Mr. Harry L. Derby, president and chairman of the board, visioned the future of the corporation.

Mr. R. A. Asbury, plant manager at Erie, Pa., in behalf of the directors, officers and employees, presented an inscribed silver platter to Mr. Derby.

Kalbfleisch Corporation was founded in 1829 by Martin Kalbfleisch. His son Franklin H. was serving as president at the time of the late war, when he resigned in favor of Mr. Harry L. Derby who has held the office since that time. A message was read from Miss Augusta S. Kalbfleisch paying tribute to the founders of the organization and the present management and expressing the hope that in the future, as in the past, the corporation will stand always for the best.

Novo Engine Company Appoints Many New Distributors

The Novo Engine Company of Lansing, Michigan, manufacturers of hoists, drag lines, engines, pumps, lighting units and similar equipment announce the recent appointment of the following distributors to handle their products: Jersey Contractors Equipment Co., 1020 W. 8th St., Plainfield, N. J.; Fitzgerald & Hudson, 150 Nassau St., New York City; Fred Lemcke, Park & Liberty Ave., Jackson, Mich.; Wylie Bros., Inc., Tulsa, Okla; R. L. McDonald, Inc., Springfield, Mo.; Anderson Tractor & Equipment Co., No. 1 W. Chapel Road, Biltmore, N. C.; Tennessee Tractor Co., 208 Fourth Ave., S., Nashville, Tenn.; Mine & Smelter Equipment Co., 306-12 S. Seventh Ave., Phoenix, Ariz; Lund & Co., 425-8 Dooley Block, Salt Lake City, Utah.

R. T. McClelland, Inc., Oakland, California, who have been Novo distributors for several years are now located in San Francisco and the firm name is Krantz-McClelland, Inc. The San Francisco address is 522 Bryant Street.

American and Concrete "Form-Hold" Merge

A report from the West brings the information that owing to growth of business the Concrete "Form-Hold" Corporation of Culver City has merged with the American "Form-Hold" Corporation, and extensive plans are being made for additional manufacturing facilities.

It is reported that the officers will remain the same, but the sales organization as well as manufacturing facilities will be increased. The American "Form-Hold" Corporation will actively administer the business of the Corporation.

Cutler-Hammer, Inc., Opens Warehouse at Cleveland

Cutler-Hammer, Inc., Milwaukee, Wis., announce the establishment of a warehouse at Cleveland, O. The company has leased 1,600 sq. ft. of floor space for the storage of stock for quick deliveries. A complete line of standard motor control equipment and wiring devices will be available for immediate shipment.

The territory to be served by these new facilities include Cutler-Hammer's entire central district consisting of the states of Ohio and West Virginia, the province of Ontario, western New York and Pennsylvania and sections of Maryland, Indiana, Tennessee and Kentucky. Sales offices for the district are located in Cleveland, Cincinnati, Buffalo and Pittsburgh.

Albany Firm Arranges to Handle Trackson McCormick-Deerings

Among the well-known distributors of general contracting machinery who have recently added tractors and tractor equipment to their lines is the E. B. Kelley Co., Inc., at Albany, N. Y., who is now handling McCormick-Deering Industrial Tractors, Trackson Tractor Equipment, and other related lines.

In addition to their establishment at Albany, these distributors have several branches in New York State and Pennsylvania. For many years they have handled concrete machinery of all kinds, derricks, hoists, pumps, and concrete plant equipment. Mr. E. B. Kelley, President of the Company, and other members of the organization are well-known to the contracting trade.

With their long experience in these fields the E. B. Kelley Company were quick to recognize the increasing importance of tractors, and especially crawler tractors, for contracting and industrial purposes. Consequently they arranged for the distribution of Trackson McCormick-Deerings, which they felt would best meet the demands of their trade.

Located as they are in the Capital of New York, these distributors are in the strategic position to get a big share of the State highway business, and they expect to do a big volume on their new lines this year.

Young Lady at Wheel of Trackson McCormick-Deering in Front of Albany Headquarters of E. B. Kelley Co., Inc.

waterworks—sewage disposal—filtration plant—power plant—chemical plant—piping and equipment

The "Q-check" symbol has been adopted as the trade-mark of the Cast Iron Pipe Research Association. Cast Iron Pipe thus marked is produced in accordance with established technical standard specifications by the leading pipe founders of the United States. Clow Cast Iron Pipe is all "Q-Check" pipe.

Insist on the "Q-Check" mark when specifying Cast Iron Pipe for gas, water, sewer, or industrial service.

Because, at Clow, ten thousand tons of pipe and piping equipment are ready now—and always—emergency, and everyday, piping jobs can be filled to better satisfaction.

What's more, Clow makes and stocks equipment carried by no other concern.

Also, Clow Engineers "take off" blue prints, accurately, completely. They estimate the exact cost of the entire piping job.

This huge Clow stock—more complete than any other—and this Clow service, can mean more profits for you, and faster, better piping jobs—gas or water.

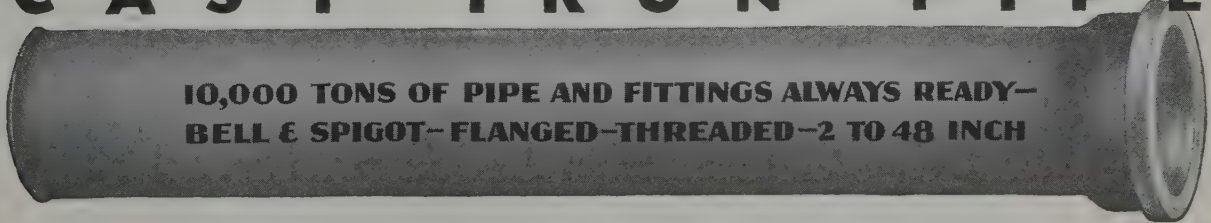
CAST IRON PIPE



E. P. Goodrich and W. B. Powell Form Association as Consulting Engineers

Formal announcement has been received to the effect that Mr. Ernest P. Goodrich and Mr. William B. Powell will be associated as consultants to municipalities on all traffic matters both in person and through assistants where required.

Mr. Goodrich, who has recently been retained as engineering adviser to the Chinese Nationalist Government, has arranged with his associates so that during his absences from the United States his clients will continue to receive the services of men of the highest reputation and experience. Mr. Goodrich has specialized on traffic matters for many years, having been a member of each Hoover Conference, of the American Engineering Council and the American Engineering Standards Committees, chairman of the New York City Aldermanic Traffic Committee and many others. He is an honorary vice-president of the National Highway Traffic Association, and chairman of the special Traffic Engineers' Committee of the National Safety Council. His traffic surveys cover nearly fifty municipalities.

Mr. Powell is consulting traffic engineer of Buffalo, N. Y., chairman of the American Engineering Council and of the American Engineering Standards Committee on Signs, Signals and Markings. He and Mr. Goodrich will undertake street traffic and related studies for cities and other governmental units, will make recommendations as to traffic signal installations, and will supervise their purchase and installation. Their New York offices are at 175 Fifth Avenue.

Eldon S. Clark Heads Consulting Service Department

The Michigan Valve and Foundry Company has recently inaugurated a new service, whereby technical advice is made available to those in charge of projects involving water supply and distribution, drainage and sewage works, particularly where piping is an important factor.

The administration of this service has been turned over to Mr. Eldon S. Clark, a well known engineer who has been associated with many important projects throughout the East.

Mr. Clark's experience since graduating from the Massachusetts Institute of Technology has included the construction of hydraulic and railroad projects for Barrows & Breed; designer and assistant engineer on power plant work and industrial building construction for Stone & Webster, and assistant engineer with Metcalf & Eddy where he was engaged in water supply and sewage disposal work, in the designing and construction of systems.

Among some of the projects with which Mr. Clark has been connected are the distribution system at Waterville, Me.; water supply work at Plattsburgh, N. Y., including a large earth dam and connecting works; extensive housing development at Hopedale, Mass., which included water supply, drainage and sewage disposal works; design and supervision of construction for additions to distribution

Eldon S. Clark

systems at both Quincy, Mass. and Revere, Mass.; in a consulting capacity on the construction work of the large earth dam now being built at Johnstown, Pa., and the investigation of the adequacy of the water supply and the requirements for distribution to districts not formerly supplied at Concord, N. H.

Mr. Clark is affiliated with both the American Society of Civil Engineers and the Boston Society of Civil Engineers. It is his intention to co-operate closely with both municipal and industrial engineers in supplying needed information in both design and construction of work under their jurisdiction. Requests for this service may be made directly to Mr. Clark in care of the Michigan Valve & Foundry Co., 3631 Parkinson Ave., Detroit.

Penn Machinery Moves to Larger Quarters

In order to care for their enormously increased business the H. O. Penn Machinery Company, 18 E. 41st St., New York City, are moving their general offices and warehouse to Bronx, according to statement of Mr. T. A. McDonald for the company.

The warehouse, now located at 134th St. and Third Ave., is being moved to Port Morris Terminal at 140th St. and East River, Bronx, New York, where extensive property has been leased. It is stated that by May 1 the warehouse and general offices will be fully established at the new location, thus placing this company in the front rank in the matter of office and warehouse facilities.

H. O. Penn Machinery Company is well known in the field of construction and industrial equipment distribution, handling Byers cranes and shovels, Chain Belt pavers and mixers, Rex pumps and saw-rigs, Butler bins and weighing devices, O. K. compressors and hoists, etc. In addition to the equipment named, they have recently secured the exclusive agency in their territory for the International Harvester tractors.

Stearns-Roger to Represent Chicago Pneumatic Tool in Intermountain Country

Announcement has been received to the effect that the Stearns-Roger Manufacturing Co. will act as agents for the Chicago Pneumatic Tool Company of New York, this to be in addition to its engineering, manufacturing and contracting business.

Messrs. Barrett, Townsend and Bartlett, who have been connected with the compressor and drill departments for so many years, will explain to all operators the merits of the various machines offered.

A complete stock of compressors, both stationary and portable, rock drills, pneumatic tools and repair parts will be carried in the Denver warehouse, 1720 California St., Denver, Colo.

Contractors Equipment Co. to Handle Manitowoc Products in Michigan

Announcement has just been made by Manitowoc Engineering Works, Manitowoc, Wis., that Contractors Equipment Company, Detroit, Mich., has taken on the sale and servicing of Moore speedcranes, shovels, draglines and trenchoes, also the Buffalo-Manitowoc clamshell bucket, in the state of Michigan.

W. T. Morgan Joins Chicago Pump

W. T. Morgan formerly with Gould's Pumps, Inc., has joined the Chicago Pump Company. He will be located at the New York Office, where he will serve as manager of Engineering Service. Architects, engineers or contractors in need of pump information will be referred to Mr. Morgan.

Sullivan Machinery Company, 122 S. Michigan Ave., Chicago, will be located at 819 Wrigley Building, 400 N. Michigan Ave., Chicago, after May 1.

SERVICE PIPE of COPPER or BRASS

protects health and cuts down repairs

COPPER AND BRASS *cannot* rust. By using them for service pipe, you protect the city water department from complaints arising from poor flow or discolored water. You safeguard the health of citizens. And you minimize the possibility of expensive repairs with consequent digging and paving work.

By urging the use of Brass for all *interior* water piping in the homes of your city, you make sure that the pure water supplied by the city will reach consumers in its original, clean, healthful state.

Copper or Brass pipe may cost a little more than the rustable or so-called *rust resisting* kind. But the many years of trouble-free service that they give make them a very worth while economy in the long run. Because they *cannot* rust, they do not leak or clog.

This association will be glad to supply full information about Brass or Copper pipe or cooperate with you to the fullest extent in any efforts you care to make toward furthering the use of these rust-proof pipes in your municipality.

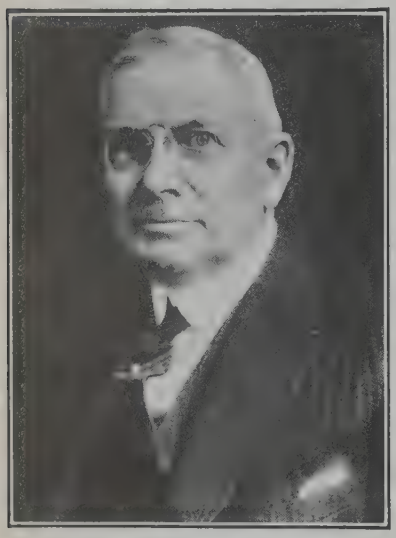
Theodore F. Merseles

The death of Theodore Frelinghuysen Merseles at Del Monte, Calif., on March 6th, removed from the business world one of its most successful organizers and managers, and one of the world's outstanding masters of practical merchandising, selling and administration.

Mr. Merseles was born August 17, 1863, in Jersey City, a descendant of Early Dutch settlers. He finished school at eighteen and began his long career of business achievement with the Pennsylvania Railroad and Trunk Line Association as clerk and stenographer.

His instinctive merchandising genius first found an outlet through the Western Wheel Works in the middle nineties when the bicycle fad was at its height.



Theodore F. Merseles

Competition in the field was intense, and as vice-president and general manager of this small company Mr. Merseles negotiated a combination with Col. A. A. Pope of Hartford and A. G. Spalding of Chicago, resulting in the American Bicycle Company, known as the "bicycle trust," with himself as vice-president.

In 1903, at the age of forty, Mr. Merseles decided to seek other fields of endeavor, and seeing opportunity in the mail order business, joined the National Cloak and Suit Company, which was then doing an annual business of about one million dollars. For eighteen years he stayed with this company, becoming vice-president and general manager. When he resigned in 1920, to become president of Montgomery Ward and Company, the business of the National Cloak and Suit Company totaled fifty million a year.

Selected by J. P. Morgan and Company to guide Montgomery Ward out of its post-war $9,000,000 deficit of 1920, Mr. Merseles with his new policies, new merchandising plans and able leadership brought this pioneer mail order house back to the top in its field until in 1926 its sales totaled over 185 million dollars and a profit of nearly nine million.

In 1927, J. P. Morgan and Company again called upon him, this time to become president of the Johns-Manville Corporation, which position he held at the time of his death. By application of his exceptional organization and merchandising ability he was again successful in increasing sales and profits, and in establishing and putting into effect further aggressive policies. The Board of Directors and Executive Officers of Johns-Manville have expressed the intention to continue and follow out all the progressive policies as planned and established by their president at the time of his death.

Mr. Merseles is survived by his widow, Mrs. Elizabeth Rich Merseles, and two sons, Herbert E. and Theodore I. Merseles. His home was in Bronxville, New York.

Chicago Pump Company Conduct School for Representatives

In order that the representatives of the Chicago Pump Company may give the architects, engineers, contractors and owners correct pump information where it is desired, the manufacturer has instituted a "Pump School," for instruction in the manufacture and merchandising of electrical centrifugal pumps. All new members of the Chicago Pump Company organization will be asked to go through the school.

The course is designed to educate the new men concerning the details of production, application of pumps and information necessary to properly figure a pump job. The production program calls for work in the machine shops, assembly floor, switch department, testing and service departments. The student also spends considerable time with experts to familiarize himself with the various conditions met with on pump jobs.

The three most recent graduates of the "Pump School" are Mr. Sidney Steiner of the New York office of the manufacturer; Mr. W. K. (Happy) Hornbuckle, representative at Memphis, Tenn., and Mr. Raymond Trethaway, who has taken the architect's engineering service, in order to cooperate with architects and engineers in Detroit, where he will assist "Tandy" Jackson.

"Business as Usual"

Mr. A. B. Chance, president of the Chance Company, Centralia, Missouri, believes in, "business as usual," despite such accidental interruption as fires.

When an explosion wrecked and set fire to the Chance Company warehouse recently Mr. Chance immediately telephoned the St. Louis Branch Office of the Truscon Steel Company for an engineer to assist in planning the replacement of the building.

Within four hours the engineer had traveled the 125 miles to Centralia and was estimating materials from hastily sketched plans. All night, while the fire burned itself out, the rebuilding program was revised and developed, and at 4:30 A. M. the contract for a new warehouse was signed while the ruins of the old one still smoked.

Work is being pushed to give the Chance Company a new Warehouse in record time. They make automobile and electrical specialties.

Cleveland Tractor Reports $100,000 in Cash Business from Two Orders

Mr. C. D. Fleming, vice-president of the Cleveland Tractor Company, reports the receipt of two large orders recently to add to this year's splendid record of sales. The orders were received from the State Highway Department of Arkansas and the Provincial Government of British Columbia, Canada, for large fleets of Cletracs.

These two orders alone, Mr. Fleming states, amount to more than $100,000 in cash business. Both orders represent repeat business for the company and bring the total number of Cletracs used by the Provincial Government of British Columbia up to eighty-two machines. The tractors are wanted for road construction and maintenance work.

The company reports notable progress in sales of large fleets of tractors to state highway departments throughout the country, individual purchases in some instances amounting to more than a hundred tractors.

Ferris Company to Handle United Tractor in Texas

The Ferris Tractor Company has been formed in Dallas, Texas, to distribute the full line of United Tractor & Equipment Corporation tractors and equipment in north and west Texas.

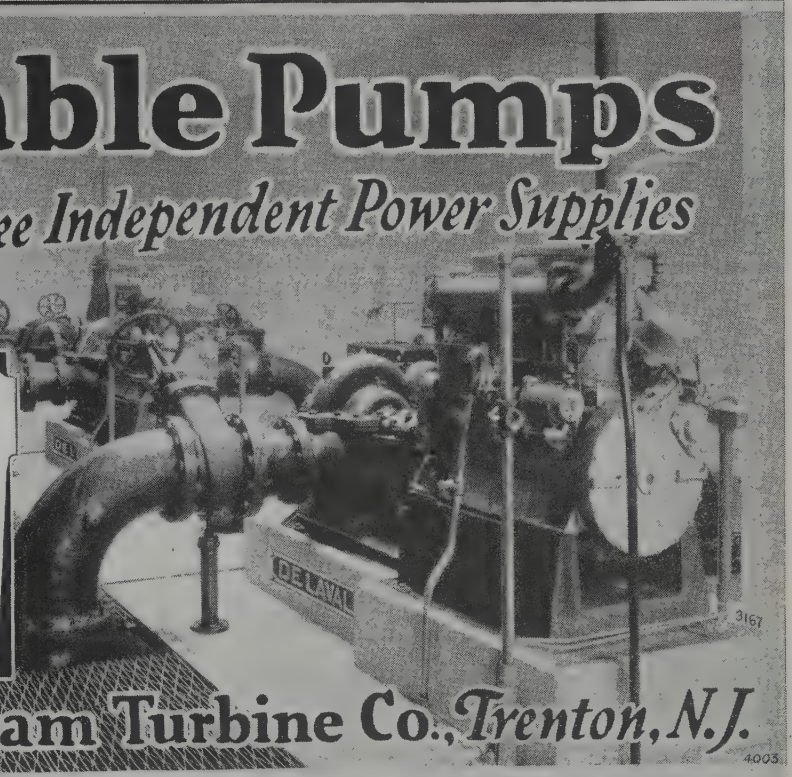
J. W. Ferris, president of the new company, has been connected with the tractor equipment business as president of the F-D Equipment Company, Fordson implement and equipment distributors, since its organization four years ago. F. A. Ferris, well known to the trade, will serve as vice-president, and H. L. Burleson as manager. Mr. Burleson has had 10 years' experience in the tractor and implement business in Texas, the past four with the F-D Equipment Company.

Change of Address

The New York Offices of Page Steel & Wire Company were recently moved from Grand Central Terminal Building to new quarters in the New York Central Building at 230 Park Avenue.

Reliable Pumps

with Three Independent Power Supplies



THE Bath Street Pumping Station of the city of Providence, R. I., is equipped with four De Laval centrifugal pumps, each having a capacity of 2000 gal. per min. against 98 ft. head. Two are driven by electric motors at 1750 r.p.m. and the other two by Sterling engines at 1200 r.p.m. De Laval centrifugal pumps are built to limit gages throughout, on an interchangeable basis. Parts subject to wear can be replaced by ordinary attendants, as the renewal parts do not require to be fitted. They are fully guaranteed as to head, capacity and efficiency, and are thoroughly tested before leaving our Works. If you are interested in pumping water or other liquids, ask for Catalog B.

ELEVATED TANKS

STANDPIPES AND STEEL RESERVOIRS

— FOR —

WATER WORKS

Bardstown, Ky.—150,000 gallons

Wherever water is needed, Pittsburgh-Des Moines elevated tanks, standpipes and steel reservoirs furnish economical, dependable storage. Large cities are giving better water service by installing several tanks for auxiliary storage in their outlying districts. Small communities are improving their systems and insuring steady pressure by installing a single central tank.

Our nearest office will gladly submit designs and estimates of storage tanks for your requirements.

SERVICE EXCHANGE
For
Manufacturers or Distributors

Editor's Note.—From time to time we receive letters from distributors wishing to be put in touch with manufacturers of certain lines of equipment, or from manufacturers seeking representatives for their products. Items of this kind will be published and names and addresses furnished interested persons upon request.

New Lines Wanted

Equipment distributor in Pacific Northwest desires line of road building equipment, structural building equipment, dump bodies and truck hoists.

Road machinery distributor would like to secure exclusive sales rights for state of Mississippi for line of automatic or self-loading wheeled scraper.

A Michigan distributor, with many years' experience, representing at this time prominent manufacturers of pumping machinery, offers the services of an established representative to manufacturers needing increased facilities in this region.

Manufacturers' representatives located in New York would like to add line of heavy contractors' equipment of established reputation, other than the lines now handled by them. They would like exclusive sales rights for such equipment.

New York company would like to represent manufacturers not already established in eastern market, or who would like to make a change in their sales arrangements.

Machinery company in the east is interested in representing established lines of road machinery, with the exception of graders.

A man of many years' experience in the machinery business in the south would like to make a business connection for the sale of road machinery equipment.

Eastern Distributor handling Brick and Clay Products, and similar commodities, would be pleased to get in touch with manufacturers desiring eastern representation.

Machinery distributor established in Porto Rico and Santo Domingo would be pleased to make arrangements to take on new lines in these territories.

Executive with 20 years' experience in selling contractors' and builders' machinery and equipment, is starting new organization and would like to hear from manufacturers desiring representation in Northern California.

A contractor's superintendent, located in Florida, would like to represent some road equipment manufacturers in his territory.

District respresentative for sanitary engineering specialties would be interested in any line in the water works field. Has had experience in field of filters, softeners and water meters.

Representatives Wanted

Manufacturer of hoisting machinery and air compressors has open territory in New York and New England states for aggressive distributor.

Manufacturer of excavating equipment desires to build up distribution organization throughout the country.

Manufacturer of non-clogging sewage pumps, both horizontal and vertical, as well as water works pumps suitable for municipalities of 50,000 or 60,000 people, is interested in securing additional sales representation.

Manufacturer of two cycle oil and gas engines in sizes from 30 to 125 H. P. adaptable for water works and many industrial purposes, wishes to establish points of distribution throughout the country.

New York corporation wishes to establish agencies throughout the country, prefer men specializing in heating and ventilating equipment.

A manufacturer of paving expansion joints is looking for distributors for northern California territory.

New York corporation, producing complete line of coal-tar products, wishes to make dealer connections throughout the country.

Manufacturer has some attractive territory available for distributors for complete line of generators, and centrifugal, diaphragm and piston pumps.

Manufacturer of metal lath, corner beads, channels and reinforcing mesh desires to secure distributors for products in the Southwest and Middlewest.

Manufacturer of building specialties wishes to establish distributors throughout the country. Manufactures concrete reinforcements and metal lath; Reed clips, form spacers, continuous column tie, continuous chair stirrup, beam bar spacers, slab bar spacers, continuous Hi-chair, continuous anchor slot, sleeping spacing anchor, humpback hairpin clip, lath hanger, stone anchors, straight wire lengths and special wire lengths.

Manufacturer of threadless pipe couplings and tees, with rapidly growing business, is seeking additional representatives.

Manufacturer of metal tie and spacer wishes to establish distributing points throughout the country.

Manufacturer of mechanical spreaders for cover material desires representation by organizations covering entire states. Several desirable states are still open. Number of inquiries now on hand for spreaders require immediate follow up.

Manufacturer of automatic dipper trip, adapted to any type shovel (steam, gasoline, diesel, electric, etc.); with rapidly growing business, is seeking additional representatives.

Our June Issue

The June issue of Municipal News and Water Works, which is to be a combination of the Water Works Convention issue and the 1929 edition of Water Works Catalog and Data Book, will contain a Geographical Index of Dealers and Distributors who handle the products of advertisers in the Catalog section.

The material for this Index was furnished by the advertisers, so if there are any distributors, representing advertisers, whose names are not listed call the attention of the manufacturers whom you represent to this in order that correction can be made when the list is revised.

The Water Works Catalog will take its place as a service book on the waterworks field as a worthy companion of the Road and Street Catalog and Data Book serving the highway field.

Change of Address

Announcement is made of the removal of the general offices of the United Iron Works, Inc., from Kansas City, to the 14th Floor of the Hunt Building, Tulsa, Oklahoma. It is stated that this location will better enable the company to care for their business in the oil industry field.

Automatic closing provides absolute safety if a break occurs

GOLDEN-ANDERSON
Patent Automatic Cushioned Controlling Float Valves

automatically maintain a uniform water level in feed - water heaters, tanks, reservoirs and pans. Very sensitive.

Operating on ½-in. to ¾-in. variation. No exhaust or expensive water waste. Can be furnished for hot or cold initial water supply. Reliable and dependable under varying pressure.

Sizes ½ in. to 24 in.

GOLDEN-ANDERSON
Automatic "Cushioned" Controlling Altitude Valves

These valves are always cushioned in closing and opening. They are extensively used for automatically maintaining a uniform stage of water in reservoirs, tanks and standpipes. No floats or fixtures inside or outside of tanks. No freezing troubles.

Three ways of closing these valves:
1st—Automatically, by water.
2nd—By electricity, if desired.
3rd—By Hand.

Sizes to 24 in.

"Works Both Ways"

Remember

Valves Cushioned at all times by air and water. No water hammer or bursting mains.

"Made with stop starter attachment for centrifugal pumps."

GOLDEN-ANDERSON
Patent Cushioned Water Relief Valves

1. Automatically relieve excess pressure.
2. Prevent stress, strain and bursting of mains.
3. Correct mechanical construction.
4. Perfect air and water cushioning.
5. No metal-to-metal seats. No hammering or shocks.
6. Angle and globe pattern. Sizes 3 in. to 24-in.

Golden-Anderson Valve Specialty Co., 1385 Fulton Bldg., Pittsburgh, Pa.

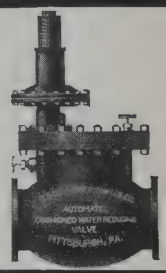
Sizes ½ in. to 24 in.

GOLDEN-ANDERSON
Pat. Automatic Cushioned Water Float Valves

1. Automatically maintain uniform water levels in tanks, standpipes, etc.
2. Instantly adjusted to operate quickly or slowly.
3. Floats swivel to any angle—Most satisfactory float valves known.
4. No metal-to-metal seats—No water hammer or shock.
5. Cushioned by water and air.

GOLDEN-ANDERSON
Pat. Automatic Cushioned Water Pressure Regulating Valves

1. Maintain a constant reduced pressure regardless of fluctuations on high pressure side.
2. Perfectly cushioned by water and air. No metal-to-metal seats.
3. The best valve made for maintaining a constant low pressure where consumption is continuous.
4. Operate quickly or slowly as required—No attention necessary.
5. Positively no hammering or sticking. Sizes to 24 in.



CAREY Elastite can be ordered in any quantity, from an armful to a trainload. And usually the shipment is on the way within forty-eight hours. Store it anywhere, pile it high—it does not weaken or warp with time.

Catalog Service

Useful Equipment Information

Watch these trade announcements for new and improved equipment

By writing the manufacturers named and mentioning this magazine, copies of the following catalogs will be sent to you without obligation

TRADE PUBLICATIONS

Meter Boxes, Valve Housings, Etc.—A new ten page folder has just been received from H. W. Clark Company, Mattoon, Ill., illustrating and describing their gray iron products. The meter boxes are equipped with Wonder Lock, the key serving as handle of box, which cannot be removed without locking box. Products shown are: Meter boxes, box covers, wonder lock, valve boxes, valve housings, extension rings, repair lids, service box wrenches, etc. Illustrations clearly bring out the advantages of these products.

Airports.—"Getting on the Air Map with Caterpillar" is the title of a very attractive booklet issued by the Caterpillar Tractor Company, San Leandro, Cal. Booklet states: "There are more than 1,000 airports in the U. S.—some still in the making. The country needs 10,000." Booklet gives much interesting information concerning what is being done in various parts of the country to meet this need. Send for a copy, kindly mentioning our magazine.

Foundries.—Three folders, of special interest to foundry men, have just been issued by the Link-Belt Company, 910 S. Michigan Avenue, Chicago. These booklets describe the Continuous Malleable Foundry of the Saginaw Malleable Iron Division of General Motors Corporation; the three foundries of the American Manganese Steel Company, and the Link-Belt Vibrating Screen. The Link-Belt Company will be pleased to send copies upon request. If writing kindly mention our magazine.

Sluice Gates.—W. C. A. No. 32 issued by Rodney Hunt Machine Company, 101 Lake Street, Orange, Mass., gives some valuable information on sluice gates and hoisting equipment. This company, manufacturers of water controlling apparatus, will be pleased to give you detailed information about their hand operated, motor operated and hydraulic cylinder operated hoists and stands and accessories for all types of sluice gates, wide bronze facings, eliminating corrosion.

Concrete Pipe.—A very attractive book, giving much useful information on the sanitary engineering field as it applies to concrete pipe, is that issued by the Independent Concrete Pipe Company of Indianapolis, Ind. It is printed on heavy enamel paper, with many clear and comprehensive illustrations and is stitched into a heavy cardboard cover of pleasing appearance, putting the information into permanent form. In addition to a short history of the field, it gives the design, specifications and manufacturing methods of Independent Reinforced Concrete Pipe. The illustrations show manufacture and installations in places described.

Reinforced Concrete Pipe.—A pamphlet issued by the Lock Joint Pipe Company of Ampere, N. J., gives complete description and illustrations of reinforced concrete pressure pipe, which is of three kinds, poured pipe, cylinder pipe and centrifugal pipe and with expansion joints of two types, "Lead and Iron Joint" and "Lead and Steel Joint." All forms are steel held by cast-iron rings, insuring great accuracy and especial smoothness. In addition to photographic illustrations booklet contains several blue print drawings. Copies may be secured from eastern office, or from Chicago branch at 110 S. Dearborn Street.

Wrought Iron.—The A. M. Byers Company, Pittsburgh, Pa., has issued in handsome pamphlet form a reprint from World's Work "The New Story of Ancient Wrought Iron," by Donald Wilhelm. This is a story of the making of wrought iron from the earliest record down to the Aston Process put into practice last year by the A. M. Byers Company at their plant near Warren, O., and for which a new plant is being constructed at Ambridge, Pa. The manufacturer will no doubt be pleased to send copy of this reprint to anyone interested.

Street Department Supplies.—Catalog No. 31 issued by the Safety Gas Main Stopper Company, 523 Atlantic Avenue, Brooklyn, N. Y., bound in loose leaf type, illustrates and describes a long list of products including gas main bags, main plugs, stoppers, gauges, pipe cleaning brushes, cylindrical stoppers for water mains, etc. The new gauge and gas bag valve combination eliminates guess work in the use of inflatable bags and stoppers on which a pump is used. The pressure gauge shows when the pressure is sufficient and whether the bag is holding or losing air.

Mixer.—Koehring Company, Milwaukee, Wis., will be pleased to send you a special circular on the Koehring Weigh Mix, a standard heavy duty mixer with weighing batch hopper and water tank mounted on an auxiliary frame. All operations are controlled from platform, all aggregate is weighed in one hopper and water weighed on same beam.

Deep Well Power Plant.—The United Iron Works, Inc., Tulsa, Okla., will send upon request literature of interest on the "Pomona" double stroke deep well power pump. Booklet contains much interesting information on deep well pumping and pumping problems.

Water Meters.—For literature on water meter setting and testing equipment write to the Ford Meter Box Company, Wabash, Ind. Meters can be set or removed in an instant. The Ford standard testers can be adapted for testing meters in a series, each meter clamped in separately and the work economically and conveniently.

Sewer Cleaning Machine and Rods.—W. H. Stewart, P. O. Box 581, Jacksonville, Fla., and branches in St. Louis and Boston, as well as factory in Walkerville, Ontario, will be pleased to send literature describing his sewer cleaning machine and conduit rods. Folder describes the hand power machine or the Wonder Bucket equipment. Sewer rods are also illustrated and described, and a list of hand tools for use with sewer rods. This sewer cleaning device will remove anything possible to get into a sewer and clean thoroughly with the least possible difficulty.

Zeolite.—The Zeolite Chemical Company, 140 Cedar Street, New York City, will be pleased to send you "Softening Municipal Water Supplies by the Use of Zeolite," a booklet which describes green sand, a natural base exchange Zeolite mineral, used for water softening. Much interesting information is given.

Stillson Wrenches.—Sando Original and Moroco Popular Stillson wrenches, formerly made by the Moore Drop Forging Co. of Springfield, Mass., are now manufactured by the Trimont Manufacturing Company, 55 Amory Street, Roxbury, Boston, Mass. The Sando has a drop forged handle and jaw, and is scientifically hardened for maximum strength. Handle is made in wood or steel type. Both Sando and Moroco are described and sizes and prices given in booklet which will be sent by manufacturer upon request.

Fire Hydrants and Valves.—The Mathews Fire Hydrants built for easy installation and so that an extension section may be used to adapt them to new grades, are described in literature of the R. D. Wood & Co., Philadelphia, Pa. A broken Mathews can be replaced is a very few minutes and without excavation or breaking up the pave-

Water Works, Once a Burden —now pays dividends with Sullivan Air Lift

For forty years, Greenleaf, Kansas, had water troubles. Many pumping systems were tried; but ample water was never certain; and repair bills in the pumping plant looked like power bills.

Then modern Sullivan Air Lift and "Air Made" Wells were adopted. The water supply became generous and permanent. And the Water Works changed from a burden on the people, to a revenue earner.

Greenleaf takes water from sand and gravel beds, forty to sixty feet from the surface. Fine screens were used in this strata to keep out the sand. But the sand choked the screens, and slowed up the wells. Coarse screens were tried, and sand cut the pumps.

But today, with the Sullivan Air Lift System—sand is repeatedly removed from the well and replaced by coarse gravel. Collecting basins grow larger and larger; and more and more water flows into the wells. Maintenance on the Air Lift System for three years was barely $10.00. And seventy thousand gallons of water are sold daily to the Missouri Pacific Railway.

There are no moving parts in Sullivan Air Lift Wells, to wear or suffer damage—no working barrels or sucker rods to pull—no trouble from varying water levels or crooked wells.

For you too—Modern Sullivan Air Lift means more water and less trouble. You will be interested in the latest information contained in the Sullivan Booklets.

Send for Catalogs.

Sullivan Machinery Company
418 N. Michigan Ave., Chicago

SULLIVAN AIR LIFT

For dependable water supply anywhere

ment. Manufacturer will be pleased to send you full information.

Chlorination. — Wallace & Tiernan Co., Inc., Newark, N. J., have had reprints made of a paper by Harry F. Ferguson (chief sanitary engineer, division of sanitary engineering, department of public health, Springfield, Ill.), and Clarence W. Klassen (assistant sanitary engineer, division of sanitary engineering, department of public health, Springfield), and appearing in the January issue of the Journal of the American Water Works Association. The title of the paper is "Are Your Wells and Reservoirs Contaminated?" The report treats of sources and reasons for water contamination, and states: "If owners of public water supplies overlook * * * or permit * * * contamination to continue * * * such owners * * * would be liable for damages for any illness * * * in accordance with recent court decisions." Wallace & Tiernan Co., Inc., will be pleased to send you a copy of this reprint, together with their technical bulletins describing their Chlorinators. Chlorination in the instances cited in the report would have protected the public health. Write for this literature.

Traffic Signals.—Catalog No. 129 has been issued by the Interflash Signal Corporation, 120 Broadway, New York City, describing Interflash "U. S. Standard" road signs and beacon signals for day and night service. Catalog describes the various types illustrated for use on highway and at street intersections where only a warning or cautionary signal is required. These are operated by either self-contained acetylene gas flushing equipment or direct from electric power lines. If interested in all-electric type of control signals ask for Catalog No. 229. For navigation lights for lighthouses, towers, buoys, wharves, bridges, etc., write for Catalog No. 329.

Chemicals.—The Kalbfleisch Corporation, 200 5th Avenue, New York, will be pleased to send you booklet on this subject in its connection with industries. The booklet is very handsome appearing, containing 84 pages, the first part being devoted to the sources, manufacture and uses of chemicals, together with a long list manufactured by the company—industrial and miscellaneous chemicals. The tables at the back of the book give atomic weights, corrections for temperatures and many other tables to serve the chemical user.

Hot Process Water Softener.—A new 12 page catalog in loose leaf style, Bulletin No. 5049, has just been issued by the Graver Corporation, East Chicago, Ind., describing their hot process water softener. Catalog gives views of installations and the component part of the softener. Booklet also contains tables showing savings made by use of softener. An extension to the front cover printed in colors enables the reader to refer to it as he reads the text of the booklet. An informative and attractive bulletin.

Paint Spray Brush.—Simons Paint Spray Brush Co. of Dayton, O., have issued a little booklet describing their paint spray brush and electric and gasoline air compressors to use with it. Containers, fittings, etc., are described and illustrations show the brush at work. For difficult painting jobs, such as large steel water towers, highway bridges, etc., this equipment saves in labor and paint. Ask for a copy of booklet G.

Tractors.—Catalog B-100 issued by Foote Bros. Gear & Machine Co., 215 N. Curtis Street, Chicago, covers all three models of the Bates "Steel Mule" tractor, 30-40-80. The Bates "Steel Mule" is easy to handle, has few wearing parts, and powered by Waukesha motor, it operates at high efficiency at all operating speeds. The crawlers run full length of tractor so it cannot nose into a bank with its radiator. Equipped throughout with IXL-ITE tool hard gears. Booklet fully illustrates, describes and gives specifications of all models.

Fire Hydrants, Gate Valves, Boxes, Indicator Posts, Etc.—A very attractive folder has been issued by the Iowa Valve Company, 701 Hubbell Building, Des Moines, Ia., giving the latest improvements on the products of this company, whose factory is located at Oskaloosa, Ia. Particular attention is called to the many improvements in the fire hydrant, such as the positive mechanical drip valve, bronze working parts, rubber mounted valve, new and improved adjusting feature which insures main valve in line with seat, all working parts removable through top of standpipe without use of special wrench or tripod, unrestricted water flow, delivering full pressure and simple construction. Folder gives description and illustration of fire hydrant and many of the other products of the company.

Chlorination. — Wallace & Tiernan Co., Inc., Newark, N. J., manufacturers of chlorine control apparatus, will be pleased to send you full information concerning their MSP Chlorinator. This equipment in duplicate is protecting hundreds of small cities by safeguarding their water supply. Records of cities where this method is in use will be furnished as well as much interesting information concerning sterilization of water.

Centrifugal Pumps.—Booklet W-67 issued by DeLaval Steam Turbine Co., Trenton, N. J., contains much interesting information concerning their geared steam turbine driven pumps, electric motor driven pumps or internal combustion engine driven pumps. Pumps for general water service, power plant service, sewage, drainage and irrigation, elevator and hydraulic pressure, marine or fire service, oil, pulp, acid, etc. Write for literature.

Planning a Waterworks System.—This is the title of a little booklet which the Cast Iron Research Association, Peoples Gas Building, Chicago, will be pleased to send you upon request. No community of 500 persons can afford to continue without a waterworks system, and many smaller towns have excellent systems. Booklet discusses Engaging the Engineer; Plans; Source of Supply; Estimating Requirements; Pumping System; Duplicate Equipment; Storage Supply; Distribution; Pipe; Hydrants; Records; etc.

Sewage Treatment Plants.—Bulletin No. 101, dated February, 1929, has just been received from the Pacific Flush Tank Company, 4241 Ravenswood Avenue, Chicago, or 9 Park Place, New York, describing the Sprinkling Filter Design using the Twin Dosing Tank Equipment. It is a very comprehensive presentation of this type of sewage treatment, and contains many detailed illustrations and data concerning large plants in use throughout the country. There are several pages of design data for single and twin tanks with percentage tables. There are also cuts and descriptions of dosing tank counter, nozzles and Marley Tees.

Chlorinizer.—Bulletin No. 20 put out by the Paradon Manufacturing Co., Arlington, N. J., gives full description of Paradon Chlorinizer. Chlorinization is in universal use for sterilization of water supplies, sanitation of swimming pools and for the disinfection of sewage. Operation, advantages, capacity, types of chlorinizers, applicability and specifications are all given in bulletin, and a list of a few typical installations is also included, regarding the Paradon equipment, a chlorinating device for small water supplies, swimming pools, and sewage plants such as in use in small municipalities, factories, camps, estates, country clubs, hotels, etc.

Cast Iron Pipe.—Write to the Central Foundry Company, 420 Lexington Avenue, New York City, for information concerning the cast iron pipe with machined hub and spigot ends, all cast iron, eliminating calking or use of any jointing material. No tool needed but a wrench.

Manhole and Catchbasin Covers.—Wm. E. Dee & Company, 30 North La Salle Street, Chicago, will be pleased to send prices and full particulars concerning their D & D Safety Cover. They guarantee this cover not to rattle or dish.

Diesel Engines.—A bulletin from the Busch-Sulzer Bros. Diesel Engine Company of St. Louis, Mo., has been issued describing the diesel power plant at Freeport, L. I., N. Y., where the 6th Busch-Sulzer Diesel—a 1,500 B. hp.—1,050 kw. unit, has just been purchased, making this the largest municipal Diesel plant in the United States, according to statement contained in folder. Their Diesel engines are built in 2-cycle and 4-cycle types, stationary and marine.

H. W. CLARK COMPANY
Manufacturers of Water Works Necessities
MATTOON, ILL., U. S. A.

Steel Storage Tanks.—Municipal Catalog No. 2 issued by the Pittsburgh-Des Moines Steel Company, 4 Neville Island, Pittsburgh, Pa., give description and information regarding the product of this company for taking care of water consumption during the peak hours and insures a constant pressure at all times. Use of these tanks eliminate fire hazards when repairs are being made at the pumping plant. Information will be furnished concerning complete water works system, pipe lines, reservoirs, filtration, purification, etc.

Fact Book of Steel Construction.—The American Institute of Steel Construction, Inc., 285 Madison Avenue, New York City, has just published a Fact Book which lists the steel fabricators of the United States, Canada, Mexico and Hawaii. It presents in chart and tables the statistics of steel, fabrication and construction work. In addition to presenting data relating to the tallest and largest buildings in the United States it also publishes for the first time the most complete list of steel bridges in the U. S. This book has been brought out because of the now general use of the skyscraper throughout the land and the widespread interest in the fabrication of structural steel.

Porous Concrete Well.—F. Thorpe, 1932 Illinois Avenue, East St. Louis, Ill., will be pleased to send you folder describing this type of well and will furnish a list of references. Some of the outstanding features are length of life, elimination of repair or maintenance costs, satisfied owners, etc.

Toledo Torch.—The new Toledo Torch "Champion" is the product of the Toledo Pressed Steel Co., Toledo, O. Write to the manufacturer for full information as to construction, service and costs.

Steel Sheet Piling.—Address Wemlinger, Inc., Singer Building, New York, or 228 North La Salle Street, Chicago, for information in regard to buying or renting steel sheet piling.

Clay Products.—Wm. E. Dee Clay Mfg. Co., 30 N. La Salle Street, Chicago, manufacturers of standard and double strength sewer pipe, drain tile, culvert pipe, well tubing, flue lining, wall coping and fire brick, will be pleased to send you full information on any or all of these products.

Sewer Flusher.—Petersen's Hydraulic Flusher Company, 277 First Avenue, Milwaukee, Wis., will be pleased to send you literature illustrating and fully describing their sewer and pipe flushers. It is made in three styles of heavy grade canvas and waterproof tubing. A labor saving tool for city, contractors and manufacturers, and an economical way of clearing sewers.

Cast Iron Pipe.—An attractive folder from the McWane Cast Iron Pipe Company of Birmingham, Ala., and Provo, Utah, shows many successful uses for this pipe. It is used in parks for feeding sprinkling systems, by railroads in yards for water, air and low-pressure steam lines, etc., all of the 2-in. size. It is also made in 4, 6, 8, 10 and 12-in. sizes. Manufacturer will be pleased to send literature illustrating and describing pipe in all sizes for all uses.

Pumps.—Bulletin P-29 issued by the Jaeger Machine Company, Columbus, O., gives illustrations, specifications and full description of diaphragm, plunger type, lift and force centrifugals. The Speed Boy is a 4-cycle high speed engine with foot starter coupled with non-clogging big volume pump with Jaeger open type brass impeller that handles 25 per cent to 28 per cent solid matter such as sand, mud or solid stones. Write for this bulletin.

Cast Iron Pipe.—A very attractive booklet called "Small Diameter Cast Iron Pipe" has just been issued bearing the name of the American Cast Iron Pipe Co., Birmingham, Ala. Types of small diameter pipe described in booklet include: Simplex Prepared Joint Cast Iron Pipe; Two-Inch Bell-and-Spigot Cast Iron Pipe; Two-Inch Prepared Joint Cast Iron Pipe; Threaded-End Cast Iron Pipe; Doublex Simplex Cast Iron Pipe; Flanged Cast Iron Pipe; Cast Iron Pipe for Vitaulic Joints; Bronze Welded Joints and Small Diameter Cement Lined Pipe. Booklet is printed on heavy enamel paper and has an extra heavy cover.

Calatom.—An admixture for concrete which is mined, milled and refined exclusively by Monterey Products Company, Monterey, Cal., and distributed east of the Rocky Mountains by Tamms Silica Company. Calatom is a low water absorption diatomaceous earth for workability and waterproof concrete. Write to the Tamms Silica Company, Stock Exchange Building, Chicago, Ill., for literature giving complete information concerning this powered admixture.

Deep Well Water Systems, Etc.—Alamo Engine Company, Hillsdale, Mich., has issued a very attractive 60 page booklet in loose leaf style, describing the use of Alamo-Dorward Rotary Power Head, for operating deep well and other types of reciprocating plunger pumps. Booklet contains cross sectional drawings, explanation of capacity table captions with several pages of capacity tables.

Meter Boxes, Couplings, Testers, Service Boxes, Etc.—Catalog No. 24 issued by H. W. Clark Company, Mattoon, Ill., gives full information in regard to their meter protection boxes, constructed of bronze, with locking device and assuring safeguard from climatic conditions. Construction provides for accessibility for repair work or replacements. Full particulars furnished on all equipment.

Gunite.—Write to the Cement Gun Construction Company, 537 S. Dearborn St., Chicago, for full information concerning this product. They will be pleased to furnish particulars and make contractors' estimates if desired.

Centrifugal Pumps.—The Byron Jackson Pump Co., Berkeley, Cal., will be pleased to send you literature giving full information concerning centrifugal pumps for any purpose. They have branch offices in San Francisco, Chicago and New York, as well as Portland, Salt Lake, Dallas and Phoenix. Their deep well turbines make available the water from deep stream sources. Write for particulars.

Cast Iron Pipe.—"Spi-Cor" is the title of a little booklet issued by the American Casting Company, Birmingham, telling the story of a new era in "culverting." It gives much interesting information in condensed form on spiral corrugated cast iron pipe. If writing for booklet, kindly give the name of our publication.

Paved Invert Culverts.—"Paving the Culvert to Combat Erosion" is the title of a comprehensive pamphlet issued by the Armco Culvert Mfrs. Association, Middletown, O. This product is designed for use where culverts carry highly sedimentary streams, on steep grades, in mountainous country, storm sewers, etc. The booklet illustrates in detail the paved invert and describes tests applied in developing it. The culvert must be made to withstand hydraulic traffic within and vehicular traffic from above. The booklet describes the Armco system. Kindly give the name of our publication if writing manufacturer for literature.

Excavator.—Write to the Bucyrus-Erie Company, South Milwaukee, Wis., or Erie, Pa., for bulletin on their D-2 Diesel Drag-Shovel. This shovel is built for the hardest work at a minimum cost. Easily convertible to clam-shell-crane, shovel or dragline. Manufacturer will be pleased to furnish you with performance records of this equipment.

Filtration Plants.—The Norwood Engineering Company, Florence, Mass., has much information on the installation of filtration plants which they would be pleased to send you if interested in municipal plants. Write for records of Norwood Municipal Filtration Plants. Kindly mention our magazine.

"The Cleaning of Water Mains."—This is the title of a booklet issued by the National Water Main Cleaning Company, 32 Church St., New York, describing the method so successfully used by them for the past twenty years. Write for a copy, giving the name of our magazine.

Well Systems.—Write to Layne & Bowler, Inc., Memphis, Tenn., or any of their representatives located in all the principal cities, for information about the Layne Water Well Systems. They will be pleased to give you the benefit of their long years of experience in this field.

When You Come To The River

You Must Know Highway BRIDGE Engineering to Carry On Profitably

To the aid of the highway engineer, county engineer and municipal engineer comes this new and straightforward treatise, "Economics of Highway Bridge Types." It fits the needs of the practicing engineer who, when his road must span a stream, meets a specialist's problem.

Such an engineer makes no pretense of being a bridge engineer. Oftentimes he does not at first grasp the scope of the problem. For it is not the problem of building a bridge, but one of *economic analysis and type selection.* Millions of dollars have been wasted through improper type adaptations, unwarranted first costs and needless maintenance expense. It is on this point that this author so squarely places his finger. Squarely and with immeasurable helpfulness. Necessarily the question of costs is exhaustively treated, and this feature of the book alone earns it a place in every civil engineer's library. Cost curves, quantitative and qualitative analyses and such factors as flood insurance, rental values, etc., bring this work a scope that assures its value. Send for a copy, read it, —then decide whether to keep it.

Centrifugal Pumps.—For a complete catalog on this equipment write to the DeLaval Steam Turbine Co., Trenton, N. J., asking for Catalog B. This is a very handsome 72-page catalog, discussing single stage and multistage pumps, for general water service, power plant service, including boiler feeding, condenser circulating and hot-well service, water works service, including main pumping units and booster, filtration and flushing service. Pumps for sewage, drainage and irrigation, elevator and hydraulic pressure, marine or fire service, oil, pulp, acid, etc. The catalog is beautifully illustrated and gives cross sectional drawings showing details of pumps. There is a section on manufacturing methods and materials, and one on testing, also just what information should be furnished in seeking plant for individual requirements. Manufacturer will be pleased to send you a copy of this informative book. Kindly mention our magazine.

Forged Steel Gate Valves.—A very handsomely bound book is catalog No. 10, issued by the Darling Valve & Mfg. Co., Williamsport, Pa., containing 32 pages filled with illustrations and giving prices and specifications of this product. Each valve is given a rigid test before leaving the factory and is subjected to hydraulic pressure equal to its rated tested pressure. If valves of standard dimensions and design cannot be used, company will be pleased to be consulted concerning deviations. If writing manufacturer, give the name of our publication, please.

Cast Iron Pipe.—For complete information on McWane Cast Iron Pipe, "what it is," "what it does," fields it serves, types, specifications, quality, special features, etc., are all told in a 54-page booklet issued by the McWane Cast Iron Pipe Co., Birmingham, Ala. The territory west of the Rocky Mountains is served by the plant at Provo, Utah, called the Pacific States Cast Iron Pipe Co., of which Mr. J. P. McWane is president. Write to the manufacturer for a copy of this booklet on McWane precalked joint cast iron pipe and fittings. Kindly mention the name of our paper.

Dipper Trip.—A folder from the Morin Mfg. Co., 896 Main St., Holyoke, Mass., manufacturers of appliances and improvements, gives illustrations and detailed information about their Universal-Semi-Automatic Dipper Trip. This dipper trip may be adapted to any make or type of shovel, steam or air, gasoline, diesel, electric, or gas-electric and gas plus air. The outstanding features of this appliance set forth in circular are ease of operation and elimination of lost motion. Write for folder describing this equipment and also the friction-type dipper trip and tag line winder for gasoline, diesel and electric, and gas-electric and gas plus air shovels. If writing manufacturer kindly mention our magazine.
